ORIGINAL LECTURES.

SHAKING PALSY.

A Clinical Lecture delivered at the Good Samaritan Hospital.

BY JAMES T. WHITTAKER, M.A., M.D.,
PROFESSOR OF THEORY AND PRACTICE OF MEDICINE IN THE MEDICAL COLLEGE OF OHIO.

(Reported by JAMES M. FRENCH, M.D.,
ASSISTANT TO THE CHAIR).

GENTLEMEN: It is pretty plain to see what is the most prominent symptom in this case—tremor; tremor which, as you see, is most visibly marked in the hands. If you make a study of the tremor in this case, you will see that it is rather more marked in the right hand than in the left. You observe that it extends also to the forearms; the arms are also slightly affected. I now call your attention to the fact, and wish to emphasize it, that there is no tremor in the head. The tremor extends also to the lower extremities; you observe that constant agitation of the legs, and perhaps you noticed when he was in bed that the feet were in constant motion too. You observe, again, a peculiar habitus of the body; you notice an inclination of the body forwards and to the left. The head is drawn down upon the body; the chin is depressed, the body is somewhat rolled up upon itself. You see that there is a peculiar expression about the face; the features have a fixed and rigid aspect; there are no changes with the emotions in a face like that. The patient has been in the house about six weeks. He has had this trembling of the hands about five years. He is now 69 years old; the tremor, then, came on at the age of 64. It attacked the left hand first, he tells us, then the right hand about a year later.

We have before us a patient who shows us some very peculiar symptoms, symptoms most marked in the hands, and accompanied by a peculiar deformity of the members affected, to which I shall call your attention a little later. The tremor first appeared in the left hand, then in the right, and then after a little lapse of time, a lapse which the patient scarcely observed, no doubt, it showed itself in the lower extremities. There is a rigid aspect of the face, an immobility of the features, and the patient talks in a monotonous, drawling tone. Now, if I were to ask you to make a diagnosis of this case, I have no doubt that many of you, and those, perhaps, who have had the best opportunity to study nervous diseases, would say that it is a case of disseminated sclerosis; but it is not sclerosis, and I have brought the patient before you to show you the difference between this disease and that. This is a case of what is commonly called "shaking palsy." But by no means every case of tremor in the aged is a shaking palsy, and the disease is not so common as perhaps you would suppose. The mistake in supposing that it is so common lies in the fact that, with the people, every case of tremor is called shaking palsy.

If we study what is to be seen in this case, you will observe in the first place that the disease attacks an old man; he was 64 when it began. This is a point of great importance, because the organic diseases which are attended with tremor generally attack young people. The most common form of tremor is chorea, St. Vitus's dance. St. Vitus's dance is, in the great majority of cases, a disease of childhood. It does occur in the adult, but such cases are rare. You know it by its bizarre, extravagant, fantastic movements; you know it by the irregular, jerking character of the movements. There is another kind of tremor which attacks extreme old age, the so-called senile tremor, that comes on in individuals most advanced in life, in individuals for the most part between 70 and 80. These are patients who suffer from the muscular atrophy of age, but that is a very different disease from shaking palsy. It distinguishes itself by attacking the muscles of the neck, so that the head and chin are in constant agitation. It is never very severe. It is plain to see that senile tremor is an expression of weakness, of the muscular failures of senescence. It would be a very exceptional case to see tremor of the head in paralysis agitans. Then paralysis agitans comes on earlier, at the age of forty, it may be. Charcot reports a case in which it appeared as early as the sixteenth year. Another case reported was eighteen; but these cases are rare, and for the most part we look upon young cases when reported as errors in diagnosis. For instance, many cases reported as cases of early paralysis agitans are cases of chorea or sclerosis. Ninety-two per cent. of the cases occur between the fortieth and the seventieth years. We see so many cases, however, between forty and fifty, that we cannot look upon it as a disease due simply to age. Senile tremor is due, then, to lack of nutrition in the muscles. This disease, however, is independent of any lack of nutrition.

Well, what is it that causes this disease? The attempt was made to show that, in many cases at least, there was a hereditary influence, but that attempt has not been very successful. It is by no means proven of it at least as clearly as it is of many other neuroses. This disease is purely a neurosis. Still Berger, who has studied this disease lately, thought that there was an element of heredity in many cases. By this we do not mean that the individual is born with the disease, but that the disease will develop in him at the period it showed itself in his parents. Calves are not born with horns, but they develop them later. In about eleven per cent. of the cases of the disease before us, he claims that there can be discovered an hereditary tendency. Nearly all neurotic diseases have a heredity as a prominent factor in their etiology. In epilepsy it amounts to about thirty per cent.

To show you how rare this disease is, I may say that, of 6000 cases of nervous disease observed in the Vienna

Hospital, there were only 37 cases of paralysis agitans. We say, then, that the disease is rare; that it occurs in advanced life; that it is to some extent hereditary. We next observe that it is sometimes due to some mental disturbance, being caused occasionally by excitement of the emotions, as by sudden fright. It is caused by domestic infelicities sometimes in women, and by financial distresses sometimes in men, for it occurs in the one sex about as often as in the other. Then it may occur as a result of getting wet, as a result of cold, we say, when we know not what else to say, and it may occur as a result of trauma. Charcot reports the case of a woman who had an injury to the leg, and in whom a tremor developed in that limb, afterwards extending to the rest of the body.

San Martin reports a case in which an injury of the arm was followed by a tremor which gradually extended to the rest of the body. Then, in a great many cases, we can not find any satisfactory explanation of its cause at all. The disease comes on in some individuals without any apparent cause. Some cases have followed typhoid fever and other infectious diseases, and some cases have followed burns.

It occurs most commonly in the hand, and most frequently in the right hand, but in this case it is most marked in the left. The tremor develops so insidiously that the individual does not notice it until his attention is directed to it by some of his friends. Another distinctive peculiarity of the tremor of this disease is that it does not occur only when he attempts to move. On the contrary, if the individual make an effort he can to a great extent control the tremulous movements for a while. In this case, however, the disease is, as you see, too far advanced for any arrest of tremor. If you tell an individual not so far along to "make a fist," he will generally succeed, and control the movements to a great degree, but, the moment he relaxes the volitional control of the member, the tremor returns. It is, therefore, not a volitional tremor, for it is somewhat, in early cases entirely, under the control of the will.

The disease may manifest itself in a number of ways. It may remain localized to one side of the body, to one arm or to one leg; it may affect the arm and leg of one side only, or it may affect both upper or both lower extremities, producing a kind of paraplegia. Sometimes it crosses, attacking the right arm and the left leg, or the left arm and right leg, but these cases are not common. There is always associated with it a paresis of the muscles; sometimes this paresis exists for several years before the paralysis ensues. Paresis you will readily detect. Put the dynamometer into first one hand and then the other, and you will find that the individual can swing the lever around with one pretty well, but it reaches only part way with the other. You notice, then, weakness and tremor; but you notice another thing, and that is the deformity which supervenes. A man who is familiar with this disease would recognize it in this case, as he walked into the room, without observing the tremor, simply from this peculiar deformity; and in some cases, I ought to say, there is no tremor at all. This is the hand of a man with paralysis agitans. The hands are bent at the metacarpo-phalangeal joints; it looks something like the deformity of arthritis deformans, but there is here no dislocation, and there are no nodular growths about the joints. You can see at once that the deformity is only a muscular affection; you can overcome it, but it soon regains its old position. The hand has the habitus of the writer. When a man holds a pen in his fingers the thumb passes under it, the forefinger over it, and the second finger around under it, and this is the position of this hand. It is often when attempting to write that this disease first makes its appearance, the individual writing in undulatory lines instead of following a straight line across the paper, and this is often noticed before the paralysis is observed. Sometimes the individual rolls the fingers as though he were rolling bread-crumbs between them, or beating a drum; but this deformity of the hand is sufficiently characteristic—the flexed metacarpo-phalangeal joints with the other joints extended. Then we notice great tension of the muscles —"Spannung," the Germans call it. There is a tension of the muscles making the deformity, and a tension of the muscles to overcome it. This is what draws the head down upon the trunk and gives the face such a peculiar expression.

In this individual the tremor does not extend to the muscles of the neck, but I see there is some tremor of the muscles about the chin and some tremor of the tongue. There is generally some tremulousness of the tongue.

There is another point to be observed in this case. When this individual attempts to walk without support he has to walk faster and faster. Nobody ever put that so nicely as Trousseau; he said that the individual has his centre of gravity before him, and he is constantly running after it. You ask the individual to take a step backwards, and he has to go faster and faster; he cannot stop until he falls over. This individual has his body so doubled up that it is thrown out of the line of gravity, and hence he has to walk rapidly in order to maintain his equilibrium. He seeks for some place to put his hands. Hence you may recognize the disease at first in the gait of the individual. You may see it in him when he rises from a chair or sits down. This man, however, is not able to rise or sit down unaided; he has gotten beyond that. In the earlier stages of the disease there is no affection of the inorganic muscles; the sphincters are not affected; but in this case there is some incontinence of urine.

With what disease would you confound it? I have spoken of chorea and of senile tremor. Then there is a mercurial tremor and a saturnine tremor, but in these cases the tremor is generally more universal, and the subjects are generally younger individuals. Then there is the history to aid you. Up to 1867 it was confounded with multiple cerebro-spinal sclerosis. Before that time it was called Parkinson's disease. He showed us how to separate it from chorea; Charcot has shown us how to separate it from multiple cerebro-spinal sclerosis. Sclerosis shows itself first generally in the lower extremities; then the agitation is not pronounced at all until the individual attempts to move himself; a man will have his hands perfectly still until he attempts to feed himself, then he is seized with a tremor. The point of distinction is that in these cases the tremor is volitional. Then, also, in multiple cerebro-spinal sclerosis we do not have this muscular tension, or this peculiar gate, or this peculiar deformity of the face or hands. Then there is no nystagmus in shaking palsy.

We separate the two diseases with a very superficial survey.

These are the only affections with which you are liable to confound the disease, and you see how easy it is to differentiate paralysis agitans. You see it in the fixation of the face, in the bending of the head upon the trunk; no disease closely resembles it, but only distantly simulates it. You will not, however, often see cases in which all the symptoms are so well marked as in this case. Mistakes do sometimes occur, for in post-mortem examinations cases of paralysis agitans, as they were supposed to be, have turned out to be cases of multiple sclerosis. In most cases, however, the lines are so distinct that he can see them who runs.

As a rare feature of this affection, we sometimes see a paresis of the eyes, and there is an inability to read. The eyes, instead of leaving the end of one line when it is read to return to the beginning of the next, will—and this is most pronounced when there are several columns on each page—run across into the adjoining column of the page. There is no lesion of the optic nerve, and no blindness occurs, as in sclerosis. Sclerosis is an organic disease, attended by organic changes in the brain; this disease, however, so far as is known, has no lesion at all. This is a functional disease, as we call it. There is no lesion, no hemorrhage, no hardness, no change in the course of the nerves, no induration, and no softening. We do find all sorts of lesions, softenings, etc., which are commonly found in the brains of old persons, but there is no constant lesion. This is a disease which as yet has no pathology. By that we mean that it is a disease with an anatomy which as yet eludes our investigations. It is a disease which, although it comes to a stand, nobody ever recovers from. Nobody was ever cured of this disease. We can make the individual comfortable to a great extent, and we will try to do that for this old man, but that is all.

I cannot repeat to you all the remedies that have been used in the treatment of these cases. Take your Materia Medica and read over the list, for they have all been tried. All the anodynes have been employed; the different preparations of opium, of which codeia seems the best, since it does not constipate. In the advanced cases we find great emaciation occurring. The emaciation is not on account of the disease, but because of the confinement to bed. That is generally the way these patients pass away, that is, by marasmus. Hydrotherapy has been found of no value in this disease. Gentle friction, massage, is of great use; the application of electricity is of use, not in the cure of the disease, but in the alleviation of the constant manifestations of the disease. Arsenic is a remedy which has been of some benefit in increasing the nutrition. Eulenberg has shown us what may be done with it. This man has been taking it for ten days, and when I went in to see him yesterday, after not having seen him for a week, I was surprised at the improvement in his appearance. The proper treatment of a case of this disease is to give him all the exercise he can take. This man must have passive exercise, for he is unable to take any other; he must have frictions, with alcohol or vaseline to prevent abrasions of the skin. Galvanization and faradization of the muscles with a very mild current would do him good. Only a mild current should be used, because a strong current only exhausts the nervous system and does more harm than good. In this way we may keep the individual comfortable for a long time, for the course of the disease is measured not by years, but by decades. There is nothing to curtail the disease. I brought the patient before you for the purpose of showing you not how to cure it, but how you can always recognize it and differentiate it from any other disease that simulates it. Its marks are very plain. Sometimes you catch it in the voice. This patient drawls his words in a monotonous tone. A sclerotic patient often disarticulates his syllables and scans his words. But there is no childish treble in this case. By the way, the childish treble is not due to age, as Shakespeare put it down. You all know very old men. How many of them have the voice that "pipes" in its sound? The childish treble is a manifestation of paralysis agitans, and often appears at the military and magisterial as well as at the age of the slippered pantaloon.

ORIGINAL ARTICLES.

TUBERCULOSIS OF THE UTERUS.[1]

BY W. J. JONES, M.D.,
RESIDENT PHYSICIAN OF BAY VIEW ASYLUM, BALTIMORE, MD.

THE purpose of this paper is to call attention to a form of uterine disease, which, though comparatively rare, seems not to have met with that recognition on the part of English and American authors to which it is entitled. Most authors — Thomas, Emmet, Meigs, Playfair, Lusk, Simpson, Cazeaux, Savage, and a few others—do not mention tuberculosis of the uterus at all, and those who do refer to this affection give it but a very slight notice.

Two cases have been seen at Bay View Asylum since May 1, 1884. These two cases, with one other, were kindly turned over to me for publication by my friend, Dr. William T. Councilman.

CASE I.—Fannie G., white, æt. 40 years; nullipara. The autopsy showed advanced tuberculosis of both lungs, tuberculous ulcers in the ilium, miliary tubercles in the liver and spleen and a few in the peritoneum. The uterus was small; flexed toward the left. On its posterior surface and in the fundus, immediately beneath the peritoneum, were two myomata as large as a pea. The uterine cavity was small and contained a small amount of caseous pus. The entire fundus was covered with a superficial ulceration, in which numerous whitish points could be made out. The distal ends of the Fallopian tubes were very much dilated, and, on squeezing them, a thick, grumous, caseous pus was exuded. The left Fallopian tube was very much twisted up and convoluted, the different parts being bound together by old adhesions. Both ovaries were rough and contracted, and of a dense, fibrous consistency. Microscopic examination of the caseous mass contained in the cavity of the uterus and in the Fallopian tubes showed the presence of abundant tubercle bacilli. Sections made through the ulcer in the uterus showed a tuberculous inflammation of the mucous membrane, The mucous membrane was wanting in most places, its place being occupied by a dense, small-celled infil-

[1] Read before the Clinical Society of Baltimore, Oct. 17, 1884.

tration which rapidly underwent caseation. In the cervix uteri there was a small hyaline plug of mucus which also contained bacilli.

CASE II.—Mahala D., colored, æt. 26 years; nullipara. Post-mortem showed advanced tubercular phthisis of the lungs, and miliary tuberculosis of the liver, spleen, and peritoneum. In the peritoneum the tubercles were most numerous in the fold between the uterus and rectum known as Douglas's cul-de-sac. The uterus was small and ulcerated over its entire inner surface. The walls were thin and the cavity somewhat dilated. It contained a quantity of caseous pus. The Fallopian tubes were enlarged, convoluted, and numerous adhesions existed between the convolutions. On section, they were seen to be filled with a dry, tolerably tough, caseous mass. Microscopic examination showed a caseous inflammation in the body of the uterus, with numerous miliary tubercles in the submucous tissues. In the Fallopian tubes the folds of the mucous membrane were involved in the caseation, and for the most part entirely obliterated, so that nothing but a caseous mass filling the entire lumen could be made out. Examination of the pus contained in the cavity of the uterus showed the presence of numerous bacilli. These were also found in the ulcerated surface and in the tubercles in this. In the latter, they were seated principally in the edge of the caseation.

CASE III. is the uterus of a woman, æt. 28 years, who had borne several children. Her last gestation was five months before her death from general tuberculosis. The uterus was of ordinary size, and contained in its fundus a large ulcer covered with a dirty, caseous mass. The ulcerative process here, as in Case I., only involved the superficial layer. The Fallopian tubes were distended, thickened, and filled with firm, caseous material. An examination of the ulcer showed the presence of miliary tubercles in the tissue beneath. Some of these were situated far down in the muscular tissue of the uterus. There was no examination made for the presence of tubercle bacilli.

That two cases should have been found at Bay View in so short a time would seem to indicate that the affection is not so rare as is generally supposed. According to Namias, tuberculosis of the uterus is met with twice in one hundred phthisical patients. Dittrich found one case in forty autopsies on tuberculous women, Peuch met with three cases in one hundred and fifty autopsies, Cless, of Stuttgart, found one in seventy, Courty found two in one hundred, and we have met with two cases at Bay View in five autopsies on tuberculous women.

Of course, one cannot argue in general from so small a number of cases, but still it would seem from this that the affection is not a rare one. According to a table deduced from data furnished by Kiwisch, "Out of 68 cases of uterine tuberculosis which he collected,"

6	subjects	were	between	10	and	20	years.
22	"	"	"	20	"	30	"
15	"	"	"	30	"	40	"
10	"	"	"	40	"	50	"
7	"	"	"	50	"	60	"
6	"	"	"	60	"	70	"
2	"	"	"	70	"	80	"

In forty-five cases collected by Dr. Geil, the uterus alone was affected but once. The uterus and tubes, with affection of the peritoneum, was found in 19 cases; without affection of the peritoneum, in 12 cases. The uterus, tubes, and vagina were all affected in three cases. Tubes alone in eight cases. Right tube alone in two cases.

Tuberculosis of the uterus is seldom a primary trouble. Some few cases, however, have been reported in which the uterus was either alone affected, or the process in the uterus was so much more advanced than in the other organs as to make it almost certain that the disease was primary here, and that the other organs were affected secondarily. Most often, though, it is one of the organs last attacked by the tubercular process. It is almost always associated with a tubercular salpingitis, and is secondary to this. In the three cases reported, this is evidently the fact. It is the result of a direct infection of the mucous membrane by the tubercular virus contained in the tubes. Still, we may have cases in which, owing to a general infection of the blood with the virus—*i. e.*, the bacilli—miliary tubercles form, just as in all other organs, from emboli.

Ordinarily, the tuberculosis of the Fallopian tubes follows on a tubercular peritonitis, and the affection of the uterus follows this. Certainly the possibility of infection in still another way cannot be excluded, viz., by coitus. In a case of tuberculosis of the prostate and seminal ducts, it is more than probable that the seminal fluid contains quantities of bacilli; and these, in case they found a suitable nidus in the mucous membrane of the uterus, might produce the disease.

The affection usually takes the form of an ulcerative process, combined with caseation. In the ulcer, miliary tubercles may or may not be found. The uterus contains generally a thick, yellowish-white, caseous mass. A similar mass is found in the Fallopian tubes, and the mucous membrane of these is in about the same condition as that of the uterus. The long, villous-like projections of the mucous membrane into the lumen of the tubes are very soon destroyed, and go to swell the caseous contents.

The seat of the affection in the uterus seems to be almost always in the body. In Case II., the ulcerative process had also affected the cervix, and might have extended into the vagina. Gusserow published, in a dissertation at Berlin, in 1859, several cases in which a tuberculosis of the vagina followed a tuberculosis of the uterus, the pathology of which is about the same as that in the uterus.

The clinical diagnosis of tuberculosis of the uterus can be based upon a persistent leucorrhœal discharge, and other symptoms which would point to uterine troubles; and in any patient of a tuberculous tendency, in which these symptoms are present, we should be led strongly to suspect an involvement of the genital organs.

The diagnosis is often aided by the expulsion of caseous masses from the uterus. The finding of such masses in the discharge as were contained in the uterus of Case II., should make us suspect very strongly the presence of a tuberculous inflammation. We have, however, now at our command one sure

method of recognition, and that is by the presence of the tubercle bacilli in the secretions. In the cases examined at Bay View, large quantities of these were found in the secretions and in the tissues after death, and there is little reason to doubt that they would also have been found during life, had an examination been made.

Siredy and Tomlinson have both shown, by published cases, that the disease is sometimes confined to the uterus and Fallopian tubes. When this is the case, it is of practical advantage for us to recognize it. For the disease may be primary here; and having developed in the uterus, would almost, without doubt, involve the other parts of the organism by travelling the Fallopian tubes and involve the peritoneum, taking a route just the reverse of that ordinarily followed.

In the event of such a case found during life, before the secondary involvement of the surrounding tissues has taken place, a knowledge of how to treat it will present itself for consideration. The authorities which I have examined upon that part of the subject have little or nothing to say. Good hygienic surroundings, tonics, and good food, and perhaps the use of iodoform topically, might at least keep the disease at bay, and thus prolong the patient's life.

NOTES OF A CASE OF HYSTERO-EPILEPSY.

BY ROBERT PATTERSON ROBINS, M.D.,
ASSISTANT DEMONSTRATOR OF CLINICAL MEDICINE IN THE UNIVERSITY OF PENNSYLVANIA.

I. E. C., aged twenty-seven years (but looking somewhat younger), unmarried, a teacher by profession, had been subject to epileptic seizures of varying intensity and frequency for eight years. The paroxysms were at one time diurnal; they were heralded by no distinct aura or premonitory symptoms of any kind, and under appropriate treatment their frequency was considerably diminished; but of late the disease had assumed the nocturnal type and was apparently intractable. That these attacks were genuinely epileptic is assumed, because in every case unconsciousness was present, and the appearance of the patient, the sallow face, the listless expression, and the dull, fishy eye all seemed to indicate the confirmed epileptic. There was apparently no connection between the advent of the epileptic seizures and the periods of menstruation, nor did the patient confess to any dysmenorrhœa or perversion of the latter function; on the other hand, menstruation began in the patient's fourteenth year, and had been always perfectly regular and comparatively painless, and the epileptic attacks did not supervene until her twentieth year. During the two years last past, her intellection, never very acute, had shown signs of impairment under the repeated convulsions, and in May last she had an attack similar in its nature (but of much shorter duration and of much less intensity) to that which is about to be described. Her family history was good, her habits of life quiet and regular, but her digestion was faulty, and she suffered from habitual constipation and hemorrhoids.

During the day preceding the attack, the patient had been peevish and listless, complaining of sore throat and loss of voice, speaking entirely in a whisper, excepting when angry or forgetful. I am inclined to believe that the sore throat was hysterical, as when I examined her throat with a light and laryngoscope twenty-four hours after the paroxysm, I found no traces even of pharyngitis, although she was still complaining of pain and dryness, and was markedly aphonic. She went to her room at nine o'clock and was asleep at eleven when the rest of the family retired. At half-past three o'clock A.M. they were awakened by her screams and ejaculations. and found her in the condition in which I first saw her, which was at four o'clock (August 6th).

The patient was lying upon her bed, forcibly restrained by several members of the family, her hair disordered and her night-dress torn, and in a wild state of excitement. Her delirium was decidedly religious in its nature, scraps of hymns and verses of the Bible being interspersed with promises to "stand up for the Lord," but inquiry afterwards failed to elicit any cause for religious excitement, and I am of the opinion that the latest subject upon which her thoughts had probably dwelt had given the color to her delirium. She did not respond to any appeals for recognition on the part of the members of the family, but I found that any directions given firmly and decidedly (such as to raise the arms above the head, to cross them upon the breast, to open or close the eyes, etc.) were promptly, but apparently automatically obeyed. After a moment, however, she would relapse into her condition of hysterical delirium. Firm pressure over the ovarian region produced neither amelioration nor any species of modification of the attack, and I may add here that during convalescence I examined the patient thoroughly from head to foot, but failed entirely to develop the hyperæsthetic point described by M. Charcot, either in the ovarian region or along the course of the spinal column. The axillary *temperature* of the patient taken at a quarter after four o'clock was 103°; as she became quieter, it rapidly ran down until at eight o'clock it was normal; during the morning, it rose again, and at twelve M. it was 102°. At five o'clock Dr. R. P. Harris saw the patient with me; the temperature was then 101.5°, and the delirium was not so violent, the pulse was rapid and feeble, and she refused her nourishment. We decided to administer nutrient enemata should this condition continue, but at eight o'clock P.M. this was rendered unnecessary by the voluntary imbibition of a pint and a half of milk with a little brandy (f℥j) and sugar. At half-past nine o'clock she fell asleep, so continued throughout the night, and the next morning (August 7th) I had the satisfaction of finding her perfectly quiet and rational, though somewhat weak. Her temperature was then normal. At the height of the paroxysm, I obtained a specimen of her urine, which, upon the application of the usual tests, showed the presence of albumen in moderate quantities (as asserted by Hippert in Virchow's *Archiv*, lix. 3 and 4, and quoted by Dr. Hartshorne in his *Essentials Pract. Med.*, p. 306). I was unable to find any tube-casts upon a microscopic examination. The patient, as far as I was able to ascertain, had no rational intervals whatsoever, between the beginning of the par-

oxysms, at half-past three A.M. on the morning of August 6th, until she awoke on the morning of the seventh at half-past six.

The treatment consisted in the administration of moderate doses of bromide of sodium (gr. x) and chloral hydrate (gr. v) every two hours. This was continued until the afternoon of the sixth, when, by the advice of Dr. Harris, the chloral was discontinued. During her sleep nothing was administered, and during convalescence, which was rapid and satisfactory, the quantity and frequency of the doses of the bromide of sodium were considerably diminished. The patient, up to the time of writing (October 24th), has had no return of the disease.

A curious case of hysteria, partaking rather of the nature of catalepsy than epilepsy, occurred in the service of Dr. Morris J. Lewis while I was an interne at the Episcopal Hospital. The notes of the case cannot be found, and I am obliged to give the details from memory.

The patient, aged about thirty-two, was admitted to the female medical ward of the hospital to be treated for dysmenorrhœa. She was short and very anæmic, and her disease was very stubborn. As far as I can remember, her family and personal history presented no points of interest bearing upon the disease. She was the mother of two illegitimate children, and had had one miscarriage. The usual course of treatment was prescribed, and the case presented no unusual characteristics until the fourth day after her admission, when the nurse hurriedly called me to the ward. I found the patient lying perfectly rigid, her eyes and mouth partly open, respiration and pulse normal, but all parts of the body entirely anæsthetic. We endeavored to arouse her by shaking, pinching, pricking with the needle of a hypodermic syringe, but without effect. Pressure over the ovarian region produced no effect whatsoever. The limbs were perfectly rigid and would remain in any position in which they were placed. The paroxysm terminated spontaneously in about fifteen minutes. These seizures recurred every two or three days; but after the first I found I could always speedily terminate them by the application of the interrupted current, one pole over the ovarian region and one at the nucha. The temperature taken at every attack was always nearly normal; the urine examined under every conceivable circumstance gave always negative results. There was no periodicity in the attacks, and a continuous course of nervines produced but little amelioration in the disease. The patient passed out of my hands when I was transferred to the surgical wards, and I have no further account of the case save the record in the hospital books that she was discharged, "improved," in August, 1881, about two months after she was admitted.

2226 LOCUST STREET, PHILADELPHIA.

MALARIAL HÆMATURIA, TREATED WITH QUININE HYPODERMATICALLY.

BY WHYTE G. OWEN, A.M., M.D.,
OF IBERVILLE PARISH, LA.

THE perusal of the history of cases presenting difficult or unique phases should not be devoid of interest to the profession, and may be of advantage "to a weary brother toiling" with another of the same description.

In the last decade the culture of rice has been extensively introduced into the sugar districts of Louisiana, which has exercised important modifications upon the types of malarial fever. Apropos of rice, I would state that the planters irrigate their fields from the Mississippi River, keeping them covered with water until the month of August, when it is turned off, leaving behind an immense quantity of fish, etc., to putrefy under the summer sun and poison the atmosphere. One result of this is that remittent fever attended with various complications is now generally substituted for intermittent, and the so-called typho-malarial fever is of frequent occurrence.

One of the complications, which is beginning to be quite common in this section, is hæmaturia, and I will give my notes of a case, recently treated, which required a departure from the usual régime:

Mr. A. N. R., aged 37, a native of Louisiana, and by profession manager of a sugar plantation, was taken sick on the 6th of September. I was called to see him on the 8th; found him in the following condition: Temperature 103½° F.; tongue coated; complaining of pain in head and back. I ordered to be taken at once:

R.—Hydrarg. chlorid. mit.
Pulv. jalap, . . . āā 0.5 gramme.
Quin. sulph., ... 5.0 "
Arom. sulph. ac., . . . q. s.
Aq. aurant. flor., . . . 60.0 grammes.—M.
S.—A teaspoonful every hour, the following morning, until five doses were taken.

Sept. 9.—10 A. M., found patient with temperature of 104° F. and urinating blood; other symptoms same as on previous day. The purgative had produced but one slight evacuation, so I prescribed 15 grammes of mag. sulph. to be taken at once, which gave six operations. The temperature declined to normal at 9 P. M. Ordered 2 grammes of quin. sulph. to be taken next morning.

10th.—8 A. M., temperature 103° F.; urine bloody. Manifests no symptoms of cinchonism. Ordered for the next morning, 3.25 grammes of quin. sulph. Temperature declined about 9.30 P. M.

11th.—9 A. M., temperature 103½° F.; other symptoms unchanged. Gave 0.25 gramme of hydrarg. chlorid. mit. and three drops of tr. acon. rad. every hour, and ordered same quantity of quin. sulph. to be taken the next morning.

12th.—Patient very weak; tongue heavily coated; temperature 103° F. Gave beef tea every two hours. Dr. Schwing was called into consultation that evening, and recommended that the patient be given every hour during the intermission 0.2 gramme each of quin. sulph. et. ferri subcarb., followed by twenty drops of arom. sulph. acid. in water.

13th.—The temperature became elevated, at 8 A. M., to 104° F.; stomach very irritable. Dr. Schwing remained all night with the patient, and administered between 10 and 12 grammes of quin. sulph., by mouth and rectum, during the intermission of six hours.

14th.—Patient very much depressed; temperature

105° F.; more blood passed than on any previous day. The patient expressed the conviction that he was a "gone case," and announced his intention of taking no more medicine, as he wished "to die in peace." I had a solution of quin. sulph. prepared and injected 1 gramme into his arm, with a hypodermatic syringe, at 1, 2, and 3 A. M. on the morning of the 15th.

15th.—9 A. M., temp. 100° F., but rose no higher during the day. Urine has been clear since last injection of quinine. 0.05 centigramme of podophyllin given this morning; milk punch during the day every two hours. At 8 P. M. an enema was given, which produced one movement of the bowels.

16th.—The same quantity of quinine was repeated this morning subcutaneously at the same hours as yesterday. No fever and no blood in urine. A large dose of hydrarg. chlorid. mit. and sod. bicarb. was given, which acted very efficiently.

17th.—1 gramme of quinine was given in the arm this morning, and two doses by mouth.

From this date the patient's convalescence was rapid, and he was able to leave for the seashore in five days. The subsequent treatment consisted of Fowler's solution of arsenic at each meal. No abscesses resulted from the injections of quinine into the arm, and its hypodermatic use undoubtedly saved the patient's life.

October 10, 1884.

HOSPITAL NOTES.

TERRACE BANK HOSPITAL FOR WOMEN, PITTSBURG.

Service of R. S. SUTTON, M.D.

ABDOMINAL SECTION FOR IRREDUCIBLE RETROVERSION OF THE UTERUS WITH DYSMENORRHŒA AND MENTAL DISTURBANCE.

Reported by W. L. STONE, M.D., Assistant.

MRS. S. R., aged 31, a woman of highly nervous temperament, was sent to the hospital by Dr. John P. Sterritt, of Pittsburg. Her married life had been a very uncomfortable one. Temporary fits of insanity took hold of her occasionally, and she would break up the furniture and clean out the ho e. When her husband exercised his authority she ould have him arrested. A number of gentlemen adjudged her insane and made out a commitment for her to Dixmont. She fled, and by some means avoided going to the asylum.

She came into the hands of Dr. Sterritt, who discovered the position of the uterus, recognized its fixidity and suspected that an ovary was also in the very tender mass supposed to be the fundus of the uterus, and that this condition accounted for her mental trouble. He sent her to Dr. Sutton for an examination and opinion. Dr. Sterritt's diagnosis was concurred in, and the patient conveyed to Dr. Sterritt a note saying, "I see nothing but an abdominal section for this case." Her menstrual periods were very painful, and between the periods pain was never absent. Sexual intercourse was always painful and often intolerable. She was admitted to the hospital on the 14th day of September, and the operation was done on the 16th, two days later.

Dr. Sterritt gave the anæsthetic. All precautions to have everything aseptic were taken, there were no spectators, and but one nurse present. Dr. Sutton performed the operation. He made an incision two inches in length and passed in two fingers of his left hand. He could not reach the fundus of the uterus or feel either ovary or tube. He extended the incision to five inches, and passed in his left hand. The uterus was found completely retroverted and fixed, the right ovary and tube were readily found, but the left ovary was not found at this effort. Expecting to need the scissors to aid in freeing the uterus he lifted the intestines out of the abdominal cavity and covered them with a warm wet towel, and I held them together above the wound as much out of his way as possible. He passed in his left hand and succeeded in breaking up the adhesions and pulling the uterus up into an erect position; he now found the left tube leading down to the left ovary still adherent, with his fingers he detached it and at once removed it with the tube, securing the stump by means of the Staffordshire knot. Having gotten the right ovary and tube, he detached the latter from an adhesion to the cæcum and removed both ovary and tube. There was some bleeding in the bottom of the pelvis, and it required considerable sponge packing and time before it was arrested. The uterus was left in position, the intestines were restored to the cavity of the belly, a big flat sponge was spread out over them, and the sutures to close the abdominal wound were introduced. The sponge was then removed. A small sponge was now passed to the bottom of the pelvis behind the uterus and fresh blood was found after several repetitions. A long glass drainage-tube was passed down and secured in the wound as it was closed. After an antiseptic dressing of iodoform and carbolized gauze was adjusted the patient was put to bed one hour from the time she began to take the anæsthetic.

On the following morning three and a half ounces of blood were taken from the tube, her pulse was 88, and temperature 99.4°. She had passed a comfortable night. Later in the day the tube was removed. During that night, the second, the nurse was napping, and the patient got out of bed and took a turn about the room. The nurse awakened and put her back to bed. She was probably dreaming, as she seemed astonished to know that he was up. She went along with pulse and temperature in nice condition, but very restless and nervous, and displaying much bad temper and obstinacy until the end of the second week. During the second week she had slight diarrhœa for a day or two. She slept some during the day and deviled the nurse all night, objecting to having the gas turned off, and insisting upon having a supply of waste paper. The latter she chewed into wads which she threw at the nurse when she wanted to keep her awake. At the end of the second week she began to eat well, sleep better, and to sit up in bed. By the end of the third week she was out of bed two hours a day, and on the twenty-sixth day after her operation she returned home in good spirits.

The result of the operation on her mental condition must be determined at a date later than the present, but after a sufficient time has elapsed to test the result, it will be reported.

The left ovary was enlarged and its capsule was torn

in detaching it. The right ovary was very slightly enlarged, possibly it was perfectly healthy; both tubes were congested. The operation was done about one week before an expected menstrual period. Some bloody discharge appeared at the vulva a day or two after the operation. The hot douche was resorted to daily until it disappeared. For many years she was in the habit of chewing snuff, and, in anticipation of a continual need of the article, had secreted somewhere a supply, and on the day after her operation the nurse detected her chewing it. It was taken away from her and she had no more during her stay at the hospital. Of this she complained bitterly, and much of her nervousness may have been due to being deprived of it.

The difficulties of operating in a case like this far exceed those of ovariotomy for cystic ovaries. The cavity of the abdomen is not distended, the bottom of the pelvis is dark, and, indeed, in the smoky atmosphere of this city it is often as dark as midnight in the bottom of the pelvis. The fingers and the sponge alone give information. Dr. Sutton is going to try the introduction, through the abdominal wound, of a small Edison lamp, into the pelvic cavity, the apparatus now in use by dentists. He has no doubt that it will illuminate the cavity with absolute safety, and expose all bleeding vessels and greatly assist in the diagnosis. The results will be communicated.

Since writing the above, Dr. Sutton informs me that he has just seen and examined the patient. Her recovery has been perfect; the uterus is in good position, and her mental condition is decidedly improved.

MEDICAL PROGRESS.

The Use of Cocaine in the Nose.—At the meeting of the Boston Society for Medical Improvement, on November 24th, Dr. F. H. Hooper spoke of the effects of this drug in a case of acute coryza. The left nostril was completely occluded, the right only partially. The sense of smell was absent. On applying a two per cent. solution of the muriate of cocaine to the interior of the nasal cavities by means of a cotton-tipped probe, free respiration was immediately established, the sense of smell returning at the same time. The nose remained perfectly free for three hours, when it began to close up again. This was followed in about an hour by a partial reopening, but at his second visit, five hours after the first application, the left nostril was again absolutely stopped, the conditions, in fact, being the same as at the morning visit. Cocaine was again applied in the same manner, and its use was followed instantly by the same result. Both nostrils have since (two days) remained opened. He had also used it in a case of chronic hypertrophy of the nasal mucous membrane, with the effect of causing a very notable contraction of the swollen tissue. Dr. Bosworth was the first, so far as Dr. Hooper was aware, to call attention to the use of cocaine in the nose. Dr. Bosworth supposes that it produces its effect by causing a tetanic contraction of the muscular fibres which are found surrounding the venous sinuses which form the erectile tissue of the nose.—*Boston Med. and Surg. Journal*, December 18, 1884.

Extrauterine Pregnancy in a Tubo-ovarian Cyst.—Dr. Vulliet, of Geneva, describes, in the *Archiv für Gynäkologie*, Bd. xxii. Hft. 3, a case which he believes to have been of the above kind. There was the history, common in such cases, of previous pelvic inflammation; of the symptoms of pregnancy, milk in the breasts, etc., and the discharge from the vagina of a decidual membrane. There was a tumor behind the uterus, pushing that organ forwards. An incision was made into the tumor per vaginam, but the wall found so thick (in consequence, as was afterwards found, of the implantation of the placenta in the lower part of the cyst) that nothing could be done by this method, and laparotomy was therefore performed, the fœtus removed, and drainage-tubes inserted both into the abdominal and vaginal wounds. The fluid contained in the sac was scanty, grayish, and fetid. The patient died on the day after the operation from septic peritonitis. On autopsy the uterus was found enlarged. The left tube and ovary were found adherent to the parietal peritoneum, and a small abscess between the tube and the ligament of the ovary. The gestation cyst was bounded in front by the right broad ligament and the uterus; behind by the rectum and the pelvic wall. The right tube was adherent to the sac, tortuous, and, when opened, was found dilated, thickened, and opening into the gestation sac. No trace of the right ovary could be found, and the most careful examination of the walls of the cyst failed to discover any ovarian structure in them. Nevertheless, from the fact that the ovary could not be found, and that the tube opened into the cyst, Dr. Vulliet endorses the view of Professor Zahn (by whom the cyst was examined) that it was originally a tubo-ovarian cyst; the ovarian tissue being, as is usual in such cysts, spread out over the wall of the cyst, but probably not recognizable in consequence of the secondary changes due to the pregnancy, death of fœtus, inflammation of cyst, etc. Dr. Vulliet has found, recorded by Cazeaux, an indubitable instance of pregnancy in a tubo-ovarian cyst. He points out, and shows from cases, that three forms of tubo-ovarian cysts are met with: (1) small and of recent formation, with the ovary unaltered; (2) those in which the ovary is wholly or for the most part converted into a membrane, but retains its proper histological structure; (3) those in which, from tension or other changes, the ovigenous tissue is destroyed.—*Medical Times and Gazette*, December 6, 1884.

The Use of Antipyretics in Fever.—At the meeting of the Society of Physicians of Vienna, Dr. Jaksch read a communication on a new antipyretic remedy. He had made a series of physiological and therapeutic experiments with the "chinolin bases," which had first been synthetically produced by Skraup. In the course of these researches he met with a body which must be looked upon as a secondary chinolin base, namely, "Tetrahydroparachinanisol," which had marked antipyretic properties. All the salts of this base dissolved easily in water, had an acid reaction and were distinguished by forming green salts when treated with ferric chloride or with any oxidizing agent. On account of this quality Skraup and Jaksch called this base Thallin, and the salts derived from it Thallin salts. Dr. Jaksch had tried the efficacy of three of these Thallin salts,

namely, the chloride, the sulphate, and the acetate, as well as another Thallin base, the chloride of aethylthallin, in eighty-six various cases of disease attended with fever, as *e. g.*, pneumonia, enteric fever, erysipelas, etc., and he found that these substances had a pronounced antipyretic action when administered in doses of gr. iijss, vijss, and xi .

The speaker remarked that experiments with new antipyretics, kairin, chinolin, etc., had shown that drugs which were only antipyretics were generally of very little use. He, therefore, suggested that further experiments with this drug should be tried on patients on account of its distinct antipyretic character, but he could not in the meanwhile answer the question whether it would obtain a permanent place in the materia medica. It should be remarked that in contrast with kairin, chinolin, and similar drugs, Thallin, when administered internally, caused no disagreeable sensations such as vomiting, cyanosis, collapse, etc., that it only now and then caused perspiration and very seldom gave rise to rigors. The antipyretic effect lasted much longer than that of kairin, and the subsequent increase of temperature developed gradually. Thallin was administered according to the following formula: R. Thallin sulph. gr. xxx, divide in doses quatuor, vel. octo. To be taken in wafer paper. Dr. Jaksch had also experimented with another drug, viz., "Parachinanisol" which, according to Skraup was about equivalent to the half molecule of quinine, but the antipyretic effects of this agent were so inconsiderable that he did not think it worthy of further trial. Another derivative of chinolin, viz., the "Tetrahydroparaoxychinolin" with which Jaksch had only experimented on rabbits, proved a strong poison, animals to which doses of from 0.6 to 0.2 grammes (gr. ½–j) had been given dying in the course of hours with strong tonic convulsions.

Prof. Nothnagel said that he had received the impression, during the last six years or so, that the employment of quinine has become a reflex phenomenon. We have begun to emancipate ourselves from the opinions which were general fifteen or twenty years ago. I would suggest that the fear of a temperature of 102.5° owes its origin to the scientific employment of the antipyretic method introduced by Liebermeister according to the method of Brandt, which in itself is an excellent procedure, and which has added much to our resources. As the treatment by cold baths is attended with some difficulty, and patients have some aversion to it, one began to employ quinine, and since then this drug has been given on a much larger scale than digitalis, nitre and nitrate of soda were employed in earlier times. The two latter have now fallen into disuse and only digitalis is now used as an antipyretic. I cherish the hope and the conviction that this false and erroneous employment of quinine will also in time be discontinued. I need not remark that the way in which quinine is, in most cases, administered, is quite incapable of diminishing temperature. Two, three, or five grains have no effect, nor, indeed, have fifteen grains if taken at intervals of twenty-four hours. Dr. von Jaksch has already remarked that the fever is not a symptom to be removed in every case; the fever, according to my conviction, which is also the conviction of many other investigators, is a most beneficial phenomenon, one of those processes of reaction which we must look upon as compensatory; we do not, however, know in what way these processes work. With respect to the infectious diseases it has been suggested that the growth of microorganisms is diminished in high temperatures; to me, however, they seem quite on the contrary to find more favorable vital conditions in fever. But attention has been drawn to a new point of view. I refer to the interesting writings of Metschnikoff, who is of opinion that the "Fagocytes" destroy the microörganisms and render them innocuous, and that these processes find more favorable conditions at a high temperature. I would only just mention it on this occasion, as our knowledge in this direction is not at all complete. Moreover, I maintain that we do not shorten the duration of the course of an acute fever, even by a single day when we have succeeded in diminishing the temperature; we even know that there are typhoid processes which run a non-febrile course without any therapeutic treatment, and in which, nevertheless, death occurs. We know of a great many accidents occurring in the course of a febrile disease which do not depend upon the high temperature, but which are due to other conditions. I do not mean to say, however, that we may be indifferent to very high temperatures. A temperature exceeding 104° must be energetically combated, but a temperature of 102.5° does not require such energetic treatment, and the less so in diseases which have a short course. This depends very much on the individual, on the constitutional conditions, and so on, and I only mention it *en passant*. In general we may say that a temperature which does not exceed 104° does not injure the patient. Every one who has had the opportunity of observing a case of recurrent fever knows that it is so. The patient suffering from recurrent fever lies in his bed with a temperature of 104°, 105°, or even 106°, quite untroubled, his sensorium is quite unaffected: when the temperature diminishes, the patient is exhausted, but we do not find that the high fever has done him much harm. To return again to the point from which I started, I maintain that it is an abuse to administer antipyretic agents, especially quinine, in temperatures of 102° and 103°, on the very first day of the treatment, when one has yet no definite idea of the development which the disease-process will take, letting alone the practical point of view, that quinine must rise in price if we employ it in all cases in which bicarbonate of soda, hydrochloric acid, or some similar drug would do as well.—*Med. Times and Gazette*, Dec. 6, 1884.

Benefits to Man from Experiments on Animals. —Until the results of the researches by Dr. Ferrier on the localization of the functions of the brain were made known to physicians and surgeons, diseased conditions intrenched within the bony cavity of the cranium had been considered beyond the resources of our art. Numerous benefits to practice have followed. Recently, Dr. Macewen, of Glasgow, reports the following case: Hemiplegia developed slowly in a female who had specific history. Vigorous treatment and counter-irritation were tried without benefit. By the advances made in recent years in cerebral localization, Dr. Macewen was enabled to become reasonably certain of the locality of the brain disease. He trephined over the middle of the ascending frontal and parietal convolutions. The internal table was thickened and rough.

A yellow, false membrane covered the dura mater; this was removed. The dura mater was somewhat thickened. An incision was made into the brain, and about two drachms of fluid escaped. The wound was closed, and it healed without the formation of matter. The next day the patient felt very much better. In three days she could move her toes; within a week she could move her fingers and the entire lower limb. In a short time, she was able to walk and do domestic duty in the hospital. Similar improvement took place in her memory and intellect. There is no doubt that the improvement was directly due to the operation. The results in this case point to the possibility that opening the cranial cavity has a much wider field than that occasioned by injuries.—*London Medical Record*, September, 1884.

Gastrostomy.—At the meeting of the Birmingham and Midland Counties Branch, Clinical Section, on October 31st, Mr. Jordan Lloyd showed a successful case of gastrostomy, performed on August 12th, for traumatic stricture of the œsophagus. Howse's operation was performed. The patient had quite recovered, was being fed through the stomach-tube, and was gaining flesh.—*British Medical Journal*, Nov. 22, 1884.

Absinthe.—At the close of a paper on this subject, Dr. Ferdinand Roux draws the following conclusions:

1. Absinthe obtained by the Duquesnel process is not toxic.

2. Absinthe is a useful drug in chloro-anæmia, convalesence from grave diseases accompanied by alterations of the digestive functions, and in the state of anorexia without lesion of the alimentary canal.

3. Absinthe is especially indicated when more or less obstinate constipation exists with the anorexia.

4. The usual dose should be about gr. jss, taken ten minutes before eating, twice a day, or a one-grain pill may be taken before each meal.—*Bull. Gén .de Thérap.*, November 30, 1884.

The Treatment of Pregnancy and Labor Complicated by Cancer of the Uterus.—In an article in the *Zeitschrift für Geburtshülfe und Gynäkologie*, Bd. x. Hft. 1, Dr. Alfred Goerner relates six cases illustrating the above complication. In one case Cæsarean section, followed by removal of the entire uterus, after the method of Freund, was performed, with the result that the mother died in nine hours. In the second case the cancer was removed during labor with the galvano-caustic wire; and one month after the labor, and again four months after, bits of cancer were scraped away, with much temporary relief; but the patient died ten and a half months after labor. The third case was a most encouraging one. Premature labor was brought on in the thirty-fifth week, and a living child born. On the eighth day after delivery the cancer was removed by the galvano-caustic wire. Two years afterwards no trace of cancer could be found, and two and a half years afterwards the patient was naturally delivered of a healthy child. The fourth case was also very satisfactory in its result. The growth was cut away with scissors, and thus room gained for the passage of the child, which was delivered with forceps, but died from asphyxia. Two days after labor the cancer was thoroughly destroyed with the thermo-cautery. Two and a half years afterwards Dr. Görner attended her for abortion with a vesicular mole, and found the cervix quite healthy. In the fifth case the growth was removed by cautery wire and cutting instruments during labor, and a living child born, but the mother survived only three months. The sixth case was treated in the same way, and a living child born; but the mother died four and a half months afterwards. These interesting cases, we think, tend to enforce the rule that in pregnancy complicated with cancer the first thing to be done is to remove as much of the cancer as possible; this proceeding being not attended with great risk, and often productive of much benefit.—*Med. Times and Gazette*, Dec. 6, 1884.

Biliary Salts in the Blood of Choleraics; Toxic Alkaloid in the Dejecta.—M. G. Pouchet reported, at the meeting of the Académie des Sciences, on November 18th, that in examining the bodies of four choleraics who died in the algid stage, he found, in the blood contained in the heart and large vessels, a considerable quantity of biliary salts. In the urine of patients who had come to the stage of reaction, he also found a large quantity of biliary salts.

In examining the dejecta of cholera patients, he found: 1. That they were almost always of a strong alkaline reaction; 2. That they contained an oily liquid, easily oxidizable and extremely toxic, which, says Pouchet, is certainly a ptomaine.—*Gazette Hebdom.*, Nov. 21, 1884.

Thallin, the New Antipyretic.—Dr. R. von Jaksch states that salicylic acid and its salts are not only febrifuges, but specifics also, whilst the other newly discovered antipyretics are only febrifuges. He has used the Thallin salt in typhoid fever with the result that the temperature fell several degrees in a few hours. The same result was obtained in acute articular rheumatism; it causes a rapid decline of fever and profuse perspiration. It seemed to have no effect upon the real disease; its antipyretic effect was also well seen in several cases of measles, puerperal fever, pneumonia, facial erysipelas, and tuberculosis.

The Thallin salts are, therefore, active antipyretics, and given in doses of gr. iijss, vijss, or xij will lower the temperature and keep it down for several hours.—*Deutsche med. Wochens.*, Dec. 11, 1884.

Subcarbonate of Iron in Surgery.—Dr. Timmermans calls attention, in the *Journal de Médecine de Bruxelles*, to the use of subcarbonate of iron in the treatment of wounds and ulcers, especially when the latter are chronic. In recent wounds it is a hæmostatic and hastens cicatrization, and rapidly heals ulcers due to excoriations or contusions. The ulcer is washed and dried, its surface and edges covered with a thin layer of the powder, and the whole covered with a pledget of lint or charpie and a bandage. During the first few days the dressing is renewed two or three times a day, according to the amount of discharge. Care should be taken that pus does not accumulate, as the iron should be in direct contact with the ulcer. (Timmermans considers it as efficacious as iodoform.)—*Medical Times and Gazette*, Dec. 11, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JANUARY 3, 1885.

FAREWELL—ALL HAIL!

THE old year has gone, and is irrevocable as the years before the flood. It is marked by important advances in the science of medicine, and has added much to the prophylaxis of disease, while new therapeutic agents or new applications of old are insignificant, unless the recent use of muriate of cocaine prove an exception.

The year has witnessed the death of many of the most illustrious in our profession, chief of whom in our own country was Dr. Samuel D. Gross. They have entered the invisible silence which few can contemplate without awe or reverence, but which so many, weary with life's years and burdens, come to entertain with peaceful hope. We are taught a too often forgotten truth that doctors like all men are mortal; that the best skill, the greatest usefulness, the largest fame cannot avert the shafts of death—cannot evade the great law—dust unto dust, ashes unto ashes.

Success and failure, sunshine and cloud, have been weaving the warp and woof of individual lives. The year brought disappointments to some, while others were made glad by hopes fulfilled; some it overwhelmed with financial reverses, while very few, if any, have escaped inconvenience, if not positive suffering from "hard times"—they have found it difficult or impossible to make outlay and income correspond; so that this new book could not be purchased or a subscription to that medical journal had to be deferred or relinquished, and even in this joyous season of gifts, in the gladdest period of the year when hearts are most open with love and kindness, wife and children could not be so generously remembered.

But what growth in professional skill, and knowledge, and in beauty and strength of moral character, in noble thought and generous feeling has the year brought to each one? It not unseldom happens that the boy home from school for the holidays eagerly measures his height by pencil-mark made on the wall or the door-jamb a year ago, and how he rejoices at the two inches or more that have been added to his stature! Is it not well for us who are children of a larger growth to measure from year to year our increase in moral and intellectual development? Mind may grow, though the body becomes old and feeble, therein giving promise and prophecy that this earthly life is not all.

To some the year brought weary, wasting sickness, and from others it took away loved ones, the light and joy of happy homes, filling the heart with a sorrow unutterable, inconsolable, and inanimate forms once radiant with all grace and beauty were laid in what faith believes is "God's field sown with the seeds of the resurrection."

But farewell to the old year, with its successes and disappointments, its gladness and grief, its crowns and crosses, its laurel and cypress.

Another year comes to wed our life—ours until death do us part, for some the parting will be by individual death, but unto most the year will die. As of old, the Doge of Venice, in official capacity, once a year, with pomp and stately ceremony, wedded the city to the Adriatic, for the sea brought prosperity; so do we wed the year whose hurrying days give us new opportunities for growth and usefulness. We may crown ourselves with rosbuds ere they wither, but let us also crown our lives with good deeds, make the world wiser or better for our living in it, help, each in his own way, each with full zeal and power, in enlarging professional knowledge, in lessening human suffering, and in lengthening human life.

Let us not carry into the new year any strife or animosity, any heart-burning or ill-will from the old, but cast them all into the deep sea of the years that are gone: "Do it straightway while the fateful future is not yet here."

All hail then to the New Year! May it be a happy one to each of our readers.

NEPHRECTOMY.

IN the issue of THE MEDICAL NEWS of last week DR. R. F. WEIR records a case of removal of a suppurating kidney through a lumbar incision, which proved fatal, in ten hours, from collapse. After securing the pedicle a severe venous hemorrhage followed the excision of the organ, which was finally controlled by plugging the wound with sponges, and which was found, post mortem, to have come from a large vein

three-fifths of an inch above the ligated pedicle. He also narrates a recovery after lumbar nephrotomy for an abscess consequent upon laceration of the organ, and states that nephrectomy has been resorted to at least 152 times, with 76 deaths, or a mortality of 50 per cent., although he analyzes only 141 cases, of which 71 proved fatal.

The kidney has been excised for wounds 5 times, with 2 deaths, or a mortality of 40 per cent.; for ureteral fistules 9 times, with 3, not 2, as given by Weir, deaths, or a mortality of 33.3 per cent.; for floating kidney 16 times, with 6 deaths, or a mortality of 37.5 per cent.; for hydronephrosis 21 times, with 12 deaths, or a mortality of 57.14 per cent.; for tumors 32 times, with 22 deaths, or a mortality of 68.75 per cent.; and for suppurative lesions 58 times, with 27 deaths, or a mortality of 46.5 per cent.

It will thus be seen that the best results have followed the extirpation of kindeys not altered by disease, as of 30 examples of the operation for wounds of the organ, mobility, and ureteral fistules, only 11, or 33.66 per cent., perished, which is less by 20.48 per cent. than for hydronephrosis, 35.09 per cent. than for morbid growths, and 12.84 per cent. than for suppurative lesions.

Dr. Weir is of the opinion that only small tumors should be submitted to the operation, or such as can be reached through the loin, since the mortality of the abdominal incision for neoplasms is 80 per cent., as against 28.57 per cent. for the lumbar incision. He also excludes hydronephrosis, since he shows that 16 cases of incision with drainage for this condition have yielded only 2 deaths, or a mortality of 12.5 per cent., as compared with nephrectomy, which furnishes a mortality of 57.14 per cent. Removal of a floating organ is also condemned, its fixation in the loin having afforded only 1 death in 16 cases, a mortality of only 6.25 per cent., while that of nephrectomy is 37.5 per cent. Hence, he concludes that the "principal, if not the sole, condition in a diseased kidney that justifies a nephrectomy is a suppurative process," from whatever cause it may arise, and that the organ should be removed by the lumbar method in the event of the failure of nephrotomy.

Dr. Weir is not singular in the opinion that a suppurating kidney should not be extirpated until after the failure of a preliminary nephrotomy, no matter whether the organ be drained through a posterior incision, as recommended by the majority of operators, or through an abdominal incision, as so successfully practised by Tait. In support of this view may be mentioned the names of Billroth, Tait, Clement Lucas, Rushton Parker, Wheelhouse, and Bryant, whose opinions are recorded, respectively, in the *Wiener medizin. Wochenschrift*, No. 24, 1884, the *Birmingham Medical Review* for July, 1884, and the *British Medical Journal* for September 29, 1883, and November 29, 1884.

In further support of this view, as well as of the greater safety of the lumbar incision, we may refer to the statistics of nephrectomy and nephrotomy for suppurative lesions. Thus, of 58 cases of the former operation collated by S. W. Gross, 27, or 46.55 per cent., died. Of the entire number, 16 were examples of laparotomy, of which 10, or 61.5 per cent., perished, while 42 were instances of removal through the loin, of which 17, or 42.8 per cent., died, the percentage of recoveries in favor of the latter procedure being 18.70. Of 37 cases of incision and drainage, on the other hand, examined by the same surgeon, only 7, or 18.91 per cent., perished; and as they include four examples of abdominal nephrotomy, they may very properly be compared with nephrectomy by both methods. Such a comparison shows 27.64 per cent. more of recoveries for nephrotomy; so that we think the rule may be safely established that a suppurating kidney should be cut into and drained in preference to subjecting it to extirpation. In formulating this line of conduct, we do not lose sight of the fact that nephrotomy leaves a permanent fistule in about one-fourth of all cases, which frequently proves to be a source of much annoyance and discomfort. In this event the shrunken sac may then be removed through the loin, as was done with uniform success, in 8 of the 37 cases to which we have referred.

Another and highly important consideration which favors a resort to a preliminary nephrotomy for suppurative lesions, is that it enables us, as pointed out by Czerny, to determine with almost a certainty the condition of the opposite organ. If, after a few days of drainage, no more pus appears in the urine, the probability is that the other kidney is sound. Should the case be one of calculous pyelitis, exploration with a needle through a lumbar incision, or pressing the organ against the psoas muscle, or exploration with the hand inserted into the rectum, or catheterization of the ureters, a device rarely practicable, may solve the problem; but should the suppuration be independent of a foreign body, either Czerny's plan, or an exploratory abdominal incision, as advised by Tait and Thornton, will be required to establish the condition of the opposite kidney. Mr. Thornton, indeed, prefers removing all diseased kidneys through the peritoneum, one of his chief reasons being that the other organ can be inspected and felt. Should nephrectomy without preliminary nephrotomy for doubtful suppurative lesions be decided upon, we think, however, that the surgeon will best consult his patient's interests by making an exploratory abdominal incision, when, if it be fitted for it, the wound can be closed and the diseased organ be removed through the loin.

Whenever it is practicable, the lumbar incision is to be preferred to laparotomy. Such, at any rate, is the view held by Czerny, Billroth, Von Bergmann, Lucas, Morris, and others, who have had the most experience with nephrectomy. The largest neoplasms can, of course, only be removed through an abdominal incision, while those of medium size can be reached by an extension of the usual lumbar incision. The ordinary vertical lumbar wound will scarcely suffice for the safe removal of a diseased kidney. Hence, Czerny and Billroth recommend Simon's incision from the border of the quadratus lumborum downwards and forwards to two fingers' breadths above the crest of the ilium, which can be carried as far forwards as may be deemed necessary for the extirpation of large tumors. Weir, in his case, obtained plenty of space by making a transverse cut, from near the top of the ordinary vertical incision, outwards for nearly five inches along the edge of the ribs. In a case of enlarged kidney, containing nine calculi, in which the organ was situated more toward the middle line, Kosinski carried an incision from the space between the eleventh and twelfth ribs, parallel to the fibres of the external oblique, to a point just above the umbilicus. Through such a mixed incision, if the term may be allowed, the operation could be made extraperitoneal or intraperitoneal, according to the requirements of the case.

Of the two abdominal incisions, that of Langenbuch, carried along the outer edge of the rectus muscle, is undoubtedly the best, and is the one preferred by Thornton. It should, however, if it be possible, be reserved for the removal of large tumors, and provision for free drainage should be made by carrying a tube through the loin.

Although we have declared our preference for the lumbar incision, hard and fast rules in regard to methods of operating can as yet not be formulated. Hydronephritic and pyonephritic kidneys should certainly be opened and drained through the loin before resorting to the more severe operation. Whether movable kidneys should be extirpated, or fixed in the loin, is an open question, since we need a much larger experience to determine the value of the latter procedure in relieving suffering. Small neoplasms should be removed through the loin; larger ones through the abdomen. Such are the axioms that we feel disposed to frame from the study of the paper of Dr. Weir, and of the many communications that have appeared upon the subject during the past three years. Be they well founded or not, it is very certain that growing experience tends to restrict more and more the operation of nephrectomy, which, under the best of circumstances, must be regarded as one of the most deadly of all surgery.

UNUSUAL SITUATIONS FOR ECHINOCOCCUS TUMORS.

ALTHOUGH echinococcus tumors are most commonly found in the liver, there would seem to be almost no situation in which they do not occur. In illustration of this, M. GÜNSBURG, of Cracow, Russia, has recently reported in the *Med. Obosrenie*, 1884, No. 6, the case of a woman aged 35, who presented herself at his outdoor service, and who had not menstruated for some months. Neither fœtal heart sounds nor placental murmur were audible. She said that nine years previously she had a lung affection, during which, after a paroxysm of coughing, she expectorated a number of white vesicles and membranous shreds. Four months after her first visit Günsburg was sent for, and found her in labor, but delivery of the head was impossible on account of the presence, in the lower segment of the uterus, of a round tumor of fleshy consistence, and as large as the fist. Its upper limit could not, however, be reached by the finger. As the child was dead, Günsburg delivered it with Braun's cranioclast. The woman left her bed in the third week. Twice during the next week, white vesicles and white membranous shreds passed out of the vagina. Shortly afterwards she became ill with cough and dyspnœa, and again expectorated the same vesicles and shreds; which, upon examination, proved to be fragments of echinococcus cysts, presenting the usual stratified layers, although scolices were not found.

More careful investigation of the case revealed the liver much enlarged, extending 4.3 inches below the border of the ribs, while numerous small inequalities on the surface of the liver could be felt through the abdominal walls. Three fingers' breadth below the umbilicus was a second movable and uneven tumor 6 inches long and 4.8 inches broad, and of fleshy consistence. The uterus was enlarged and extended 1.2 inch above the symphysis pubis in the left lateral position. Examination per vaginam revealed a bladder-like swelling with thick fleshy walls. In the thorax, dulness extended much higher than was normal on the right side posteriorly.

Echinococcus tumors of the uterus are exceedingly rare. Only one other case producing difficult labor has been reported, at Isumi, also in Russia. In this instance the woman was also delivered by craniotomy. In addition to this, however, four other cases of echinococcus cysts of the lesser pelvis, in association with the non-pregnant state, are reported in Russian literature. In one case, the tumor, proceeding from the liver, was diagnosticated as an ovarian cyst and operated upon, with a fatal termination. In another case laparotomy was performed and the patient recovered.

A knowledge of the possible occurrence of such cases may serve to prevent errors in diagnosis otherwise unavoidable.

Still another unusual situation for echinococcus cysts is the neck, a case of which is reported in the *Festschrift des ärtzlichen Verein*, by Dr. Lindpainter, who was called upon to do tracheotomy in a patient who had noticed enlargement of the left side of the neck from his earliest youth; and in whom more recently a tumor as large as a fist had developed behind the sterno-cleido-mastoid muscle, forcing the trachea out of place and compressing the œsophagus. Dyspnœa resulted, while fluids alone could be swallowed, and that with difficulty. Fluctuation was discovered, and, after a couple of punctures, accompanied by the discharge of a transparent fluid, the trachea straightened itself, and the breathing became easy. Examination of the clear watery fluid revealed numerous hooklets. The cyst was subsequently freely opened and a drainage-tube temporarily inserted. Complete recovery ensued.

THE SIGNIFICANCE OF ALBUMINURIA IN STRANGULATED HERNIA.

WHILE, at first thought, it would appear that the special value of albuminuria as a diagnostic sign must diminish as the number of conditions of which it forms a part is found to increase, closer investigation is gradually proving this to be an error. It is true of this, as of all other conditions, that the more we know of it the more accurate are the deductions we may draw from its presence, although such a state of affairs may be preceded for a time by another in which doubt and uncertainty seem uppermost.

In proof of these statements, we may refer to some recent extended studies by DR. JOSEPH ENGLISCH on "Albuminuria in Strangulated Hernia," published in the *Wiener med. Jahrbücher* for 1884, Hefte 1 and 2. He concludes that, in certain strangulations of the bowel, certain derangements in the renal functions ensue, including albuminuria, and in extreme degrees anuria. In what manner these derangements are produced—whether through scanty water absorption, the loss of liquid by vomiting, irritation of the kidney by the absorbed altered intestinal contents, or by deranged innervation of the intestine—he leaves to future researches, by the aid of chemistry and instruments of precision, but he is inclined to ascribe them to the presence in the blood of absorbed products of decomposition.

The albuminuria thus caused has both a diagnostic and prognostic value. When present, we may infer that a loop of gut is being strangulated, while, if the other symptoms of strangulation are present without albuminuria, we may conclude that it is an appendage of the bowel which is incarcerated, or a portion of the omentum, or that we have an inflamed hernia to deal with. The presence of the albumen also shows that the strangulation of the bowel has reached a degree which is dangerous to the individual. This is still more certain if there are found in the urine cellular elements derived from the kidney, its pelvis, the bladder, and ureters. The presence of the symptoms of collapse, with sudden increase in the quantity of albumen, announces the supervention of gangrene. The addition to the above of nervous symptoms of a decided character point to uræmia.

As to treatment, where albumen is present, only gentle taxis should be used, and, should this fail, section should be performed, and experience has shown that resection of the bowel, under these circumstances, is often a successful operation.

These are very striking results, and at first thought seem to promise too much. They are, however, easy to refute or confirm. Englisch indeed says of them that they are only a contribution to the symptomatology of strangulated hernia, the exact value of which can only be determined by numerous observations, to which we hope American surgeons will not be slow to contribute.

THE TRANSMUTATION OF BACTERIA.

THE subject of the genetic relations of the different varieties of cleft fungi is admitted on all sides to have a most important bearing upon the question of the germ theory of disease. The relation of the hay bacillus or bacillus subtilis to that of anthrax is a subdivision of this subject which has claimed considerable attention, and at the recent Congress of German Naturalists and Physicians, PRAZMOWSKI read a paper upon it, to the more important points of which Dr. Gaffky calls attention in the *Deutsche med. Wochenschrift*, November 20th.

It will be remembered that Buchner, in 1880, announced that he had, by appropriate cultivation, converted the bacillus of anthrax into the hay bacillus, and *vice versa*, although he himself had said that the mode of germination was different in the two bacilli. Prazmowski has called attention to the fact that the significance of this difference has not been appreciated, while Koch, Gaffky, and Klein have also shown that Buchner's experiments were defective, and the conclusions based thereon not justified. Prazmowski has shown how that, while in the hay bacillus the spores so germinate that the young rods burst forth laterally, that is, vertically to the longitudinal axis of the spore, in the anthrax bacillus they perforate the membrane in the direction of the longitudinal axis, at one of the two ends.

Prazmowski has further demonstrated that it is not true that under certain conditions of cultivation one organism is developed, and under others, another, but that we have to do throughout with two distinct

bacteria, and that the mode of germination of anthrax spores is equally characteristic and unalterable as that of the hay bacillus, and *vice versa*, and that this difference is due to the anatomical structure of the spore-membrane. Still another anatomical difference between the anthrax bacillus and the hay bacillus is found in the fact that the former is unprovided with cilia, while the bacillus subtilis has, as Brefeld has shown, two long cilia at each end. From all of these considerations, Prazmowski concludes that the genetic relation which Buchner sought to establish between the anthrax bacillus and the hay bacillus does not exist.

If these conclusions are confirmed, a most important objection to the acceptance of the germ theory is removed; and we feel bound to state that, in our judgment, the evidence of Koch and Prazmowski outweighs that derived from the apparently less guarded experiments of Buchner, although the latter are supported by Nägeli.

REVIEWS.

ON HEALTH RESORTS.

1. WIESEN AS A HEALTH RESORT IN EARLY PHTHISIS, WITH DIRECTIONS FOR CLOTHING, DIET, AND EXERCISE IN THE SWISS ALPS DURING WINTER. By A. T. TUCKER WISE, M.D., L.R.C.P., M.R.C.S. Formerly Visiting Physician to the Infirmary for Consumption, Physician to the Western General Dispensary, etc. Pp. 68. London: Baillière, Tindall & Co., 1883.

2. THE ALPINE WINTER CURE, WITH NOTES ON DAVOS PLATZ, WIESEN, ST. MORITZ, AND THE MALOJA. By the same Author. Pp. 83. 1884.

THE latter of these little volumes, which is largely a reprint of the former, constitutes a useful guide to invalids driven by pulmonary maladies to Switzerland, and is an important contribution to a solution of the sanitary problem in regard to the value of high altitudes in phthisis. Our author is a strong advocate for the advantages derivable by *poitrinaires* from a dry frosty atmosphere in localities elevated at least five thousand feet above sea-level, and claims that the drawbacks for patients in the first stage of consumption at least, are chiefly due to faulty sanitation of dwellings and their local surroundings. The influence of diminished pressure in producing hæmoptysis might well have been considered more at length, but much valuable advice is given in regard to diet, clothing, exercise, and so forth, at these resorts. It is so customary for British reviewers to triumph over any typographical errors or imperfections in the mechanical execution of works published in this country, that we cannot resist calling their attention to the word "damnness" near the bottom of page 13, which, as applied to the climate of Wiesen, affords an evidence either of careless proof-reading or of profanity, which we would be sorry to see displayed in an American book.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, December 9, 1884.

THE PRESIDENT, ROBERT F. WEIR, M.D., IN THE CHAIR.

THE discussion being in order of Dr. Weir's

REMARKS ON EXTIRPATION OF THE KIDNEY

(see THE MEDICAL NEWS, December 27, 1884, p. 707),

DR. HALSTED said that, irrespective of the question of comparative risk, one would admit that neoplasms of the kidney may be more satisfactorily dealt with through the abdominal incision. Certain operators who were complete masters of the technique of abdominal surgery would be justified in preferring and practising laparotomy in the removal of kidney tumors, whereas the great majority of surgeons may prefer, for the present, to confine themselves to the lumbar incision. Each surgeon should, therefore, be the conscientious judge of his own attitude. Thus it is easy to comprehend why von Bergmann, Thornton, Tait and others should adopt the abdominal incision; and, although Tait will not confess the secret of his success, it is quite apparent to others that it is to be ascribed to operative skill and most careful asepticism. Dr. Halsted was inclined to advocate, for the abdominal incision, a line lateral to that recommended by Langenbuch, for two reasons: 1st, to avoid, if possible, subsequent hernia, and 2d, to enable one, early in the operation to sew off the operation field from the general peritoneal cavity. It seemed to him that the suggestion from Hagen-Torn (*Centralbl. für Chirurg.*, No. 35, 1884), to cut through the musc. rectus abdominis rather than through the linea alba to prevent hernia after ovariotomy, was a good one. He advised also that especial attention should be paid to the sewing of the incision through the oblique and transverse abdominal muscles. A cross-cut of such a wound would give two lines, irregularly concavo-convex, demonstrating, that the various tissues divided had retracted unequally, and that to make the cut surfaces offer the broadest possible face, it would be necessary to convert the undulating into plane surfaces. This could be done by one or more rows of buried sutures aimed at the concavities. To enable one to operate outside of the peritoneal cavity, Dr. Halsted recommended a procedure to which he had resorted in his case. The abdominal cavity was entered along Langenbuch's line. In future cases he would enter outside of this line, as just described. In front of the carcinomatous kidney was the descending colon. The parietal peritoneum was a second time divided about three inches from the outer border of the colon and the kidney readily removed. The hemorrhage from the kidney-bed was rather profuse, from, perhaps, about one hundred oozing points. This was only partially controlled by about as many catgut ligatures. The peritoneal cavity was then closed off from the field of operation by uniting the mesial edges of the twice-divided peritoneum. Thus an extra-peritoneal cavity was formed, bounded postero-externally by the kidney-bed and the abdominal parietes which had been

robbed of its peritoneum; antero-externally by the isolated strip of peritoneum, the margins of which were the lateral edges of the original parietal incisions, and internally by the outer surface of the somewhat curtailed peritoneal cavity. The extra-peritoneal cavity was drained (anteriorly) by two large rubber tubes. The hemorrhage stopped at once from intestinal pressure, and convinced the operator that he might have spared himself much trouble and the patient some shock, if, instead of applying so many ligatures, he had earlier closed off the peritoneal cavity as described. The patient recovered rapidly from the shock of the operation and passed a comfortable night. In the morning he developed uræmic convulsions which recurred at intervals until his death, about twenty-seven hours after the operation. He secreted in this time only ℥jss of urine. A complete autopsy was not allowed. Injection of the extra-peritoneal cavity demonstrated that the peritoneal cavity had been completely shut off. In the latter was about ℥j of slightly stained serum, but no other evidences of peritonitis. Microscopical examination revealed advanced interstitial disease of the right kidney.

Dr. Halsted thought it fair to attribute the convulsions to the condition of the right kidney, for the patient's pulse was too strong to make it probable that diminished blood-pressure alone might have been the cause of the oligouresia.

FRACTURE OF THE BODY OF THE TWELFTH DORSAL VERTEBRA.

Dr. E. L. Keyes presented a specimen of fracture of the spine and dislocation forwards, accompanied by the following history: George H. McM., twenty-eight years of age, by occupation a driver, was admitted to Bellevue Hospital, November 15, 1884. His family history was good. The patient had a chancre six years ago. On November 18, 1884, the patient was standing in front of his horses when they started to run, knocked him down, and the axle of the truck struck him on the back as it was dragged over him. The wheels did not touch him. He was at once paralyzed. The patient was taken to Chamber's Street Hospital, and transferred to Bellevue on the following day, where he was examined and found to have total paralysis of motion below the umbilicus; sensation was not entirely lost, but was much blunted. It persisted for a long time, but could not be referred at all accurately to its proper source. The nature of the sensation was not recognizable. There was complete retention of urine. There was pain on pressure over the spinous process of the twelfth dorsal vertebra. This process was separated by twice the normal interval from that of the eleventh, and seemed to be displaced forward. The patient was placed on a water bed, and the urine was drawn by catheter three times a day.

November 16.—The patient vomited occasionally during the night, and had a burning pain near the left anterior superior iliac spine.

17th.—Considering that the elevation of the displaced spinous process and lamina was the only possible means of relieving the spinal cord from pressure, Dr. Keyes asked his house-surgeon, Dr. Pinkerton, to cut down upon the spine, and remove the depressed bone. A crucial incision was made, the muscles separated from the spinous processes, then pulled aside with retractors. The articular processes were then felt to be displaced from one another, admitting the index finger between their surfaces, the inferior of the eleventh and the superior of the twelfth dorsal vertebra. It was impossible to make out any fracture of the laminæ of the spinous process and laminæ of the eleventh, and the spinous process of the tenth dorsal vertebra were removed with the *rougeur*, the latter simply to give room to work in. There was a slit in the dura about one-fourth of an inch in length, which was accidentally increased to three-eighths of an inch by being caught between the forceps and the bone. The spinal cord felt firm and normal. After removal of the bone the cord was entirely free from pressure. The operation was thoroughly antiseptic. A rubber drain was inserted and the wound was dressed antiseptically. Stout zinc splints were applied to the back.

18th.—Temperature 99° to 100° F., and the patient feels a tingling in his feet, but is otherwise perfectly comfortable.

19th.—Examination of the urine showed specific gravity of 1010, albumen and blood. Temperature from 99° to 103° F.

20th.—At 1 P.M. the patient had a chill. The temperature rose to 104.75° F., and the wound was dressed. No pus was found; discharge only slight.

21st.—Temperature continued high. The patient feels badly, but has no pain, no increase of paralysis or of anæsthesia. Incontinence of urine and involuntary evacuations from the bowels continued.

22d.—The patient died at 5 P.M.

Autopsy. The appearance of the wound was healthy. Primary union of the incision. All of the organs normal except the spinal cord. The portion between the tenth and twelfth dorsal vertebræ was very soft. There was meningitis and acute ascending myelitis.

Dr. Halsted referred to a case in which he had trephined the vertebral column for a rotation-luxation forwards of the twelfth dorsal vertebra. The patient, male, aged about fifty, had been so caught between the top of an ascending elevator and a beam as to exaggerate the lower part of his dorsal arch. He was at once brought to Roosevelt Hospital (September, 1884). Examination revealed a depression and loss of spinous process at about dorso-lumbar junction. Just below the depression, on a line with the dorsal spines, was a sharp bony process which Dr. Halsted believed to be the transverse process of the vertebra below the dislocated one. There was complete paralysis of motion and sensation in the lower extremities. The abdominal reflexes seemed to be exaggerated, and all reflexes, superficial and deep, below these were absent. Retention of urine, and, two days later, incontinence of feces. Albumen and casts in urine. On the third day after receipt of injury, operation as follows: An incision in the median line, through badly contused soft parts, was made over lower dorsal and upper lumbar vertebræ. The spine of the dislocated and rotated twelfth dorsal occupied the frontal and sagittal level of the left upper articular process of the first lumbar vertebra. The right transverse process of the first lumbar vertebra, with its fractured tip, was thus driven into the muscles of the loin. Over the spine of the last dorsal vertebra were traces of central nervous matter. The left articular process of the first lumbar and spine of twelfth dorsal

being cut away, a strong Langenbeck's hook was inserted in the laminar fork of the twelfth dorsal. The patient was then doubled ventrally, and at the same moment pressure exerted by the hands of an assistant from behind forwards on the lumbar vertebræ, and traction backwards, by the Langenbeck's hook, of the twelfth dorsal vertebra reduced the displacement with a snap. Reduction of the dislocation was easily maintained. Patient did not, apparently, suffer shock from the operative interference, but died seventeen hours later. One of the internes stated that, shortly after the operation sensation extended almost to the knees. Before the operation, there was no sensation in parts below the distribution of the first lumbar nerve.

Autopsy. Double pleurisy with fracture of seven ribs on the left and of four on the right side. Both lungs œdematous. Fluid in pericardium. Small granular kidneys. Operation wound. Dislocation remains reduced. Comminuted fracture of body of first lumbar vertebra, a small opening into left pleural cavity between eleventh and twelfth ribs. Spinal cord (lumbar enlargement) completely severed and considerable effusion of blood in dural sac in the dorsal region.

DR. SANDS said that in Dr. Keyes's case the persistence of complete paraplegia after the removal of the depressed bone by trephining rendered probable a disorganization of the cord opposite the seat of fracture, which would make any operative procedure unavailing.

DR. HALSTED was quite sure that Brown-Séquard had demonstrated, experimentally, that wounds of the spinal cord may heal and its function be restored. Also that other investigators had observed regeneration, in animals, of excised portions of the spinal cord, and, furthermore, he thought there was clinical evidence sufficient to make it probable that, even if crushed, the cord might regain its function.

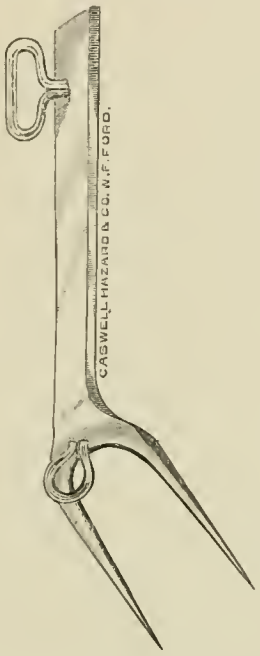
DR. STIMSON remarked that the question of trephining for fracture of the spinal column had been discussed for many years. The fact that the pressure which is sought to be relieved is made on the front of the cord by the displaced body of the vertebra, in a region which is not accessible for operation, indicates that the only value which trephining is likely to afford is that observable in Dr. Halsted's case, namely, to afford opportunity for the introduction of an instrument with which to correct the deformity.

DR. KEYES thought the fact of the existence of acute ascending myelitis, with blood-clot opposite the sixth vertebra, above the point of injury, would have made any other procedure inoperative in this case. The pressure seemed to be relieved at the time of the operation, but probably it was not.

FORK FOR FRACTURE OF THE PATELLA.

DR. L. A. STIMSON showed a fork to be used in the treatment of fracture of the patella. He had expected to show a patient upon whom he had used it with success, but the man had failed to come.

In using Malgaigne's hooks he had found it difficult to insert the hooks deeply enough to adjust the screw that connects them, and he had devised this fork as a substitute. The fork is of iron, two-pronged, the prongs bent in the flat at an angle of forty-five degrees at their junction with the shaft. The prongs are one inch long and three-quarters of an inch apart; the shaft is about three inches long. There is a small ring at the base of the prongs for the attachment of an india-rubber cord, and another at the end of the shaft for the attachment of a bandage encircling the thigh.



The instrument is used by inserting the prongs through the skin above the patella and pressing them down until they rest against the upper border of the upper fragment; the shaft lies along the median line of the front of the thigh, and is prevented from tilting or moving to either side by a roller bandage wrapped around it and the thigh. Traction downward is made by a piece of India-rubber tubing, one end of which is attached to the ring at the base of the prongs and the other made fast to the front of the skin by adhesive plaster. The introduction of the prongs can be made easily and painlessly by chilling the skin with ice and making two punctures with a knife.

In the case he had treated with this fork the fracture was transverse and the separation about an inch. The separation was readily overcome by the traction. The patient made no complaint during the five weeks the instrument was in place. The patient was kept in bed, with the limb suspended in a wire gutter, and the punctures kept dusted with iodoform; there was no inflammatory reaction about them, and only a slight discharge. The lower fragment was kept gently pressed upward by an oblique turn of a roller bandage. On the removal of the fork, five weeks after the occurrence of the fracture, the fragments were closely and firmly united, without independent mobility. As a precaution, a plaster bandage was then applied, and not removed until the end of the ninth week. The knee could then be flexed nearly to a right angle, and there was still neither independent mobility nor separation of the fragments.

DR. J. L. LITTLE exhibited Haid's electric battery, designed to give electric light to aid in the performance of operations within cavities.

CINCINNATI ACADEMY OF MEDICINE.

Stated Meetings, December 1 and 8, 1884.

THE PRESIDENT, W. H. WENNING, M.D., IN THE CHAIR.

(Specially reported for THE MEDICAL NEWS.)

DR. THAD. A. REAMY reported the following

FATAL CASE OF MORPHIA NARCOSIS FROM THE HYPODERMIC ADMINISTRATION OF A QUARTER OF A GRAIN.

Mrs. L., aged 28, a blonde of medium height, light eyes, phlegmatic temperament, large, robust, and well developed, weighing 165 pounds. She menstruated first at the age of 12, married at 20, and at the age of 23 gave birth to a healthy male child. The labor was natural. She never had a miscarriage. Her health and menstruation previous to confinement were both normal. Since her confinement, and during the time that she was under observation, the most important subjective symptom was pain in the pelvic region, constantly present, but exaggerated at the menstrual periods. She had also a constant feeling of languor since her confinement, especially after any exertion, when the localized pain was also increased. Her strength was not in harmony with her development and physique. Physical examination revealed no lesion of heart or lungs. The kidneys were supposed to be sound, in the absence of any symptoms to indicate disease. Examination *per vaginam* revealed a slight laceration of the cervix uteri and of the vaginal portion of the perineum. Some chronic cervical endometritis was also present with the characteristic discharge. In the bottom of the cervical laceration there was a firm cicatricial plug which was supposed to be the cause of the reflected pain.

At twelve o'clock, on the 29th of the month, the patient was operated upon for the cure of these two difficulties. The cervix was operated upon first, and three sutures were inserted for the closure of the lips after they had been denuded. The vagina was then operated upon. The latter operation did not involve the external perineum, but only the vaginal portion, as stated. The two operations together did not occupy more than from twenty-five to thirty minutes. After ten or fifteen minutes had been given for the patient to recover from the anæsthesia, she was taken to her bed. Although the quantity of ether used had not been measured, the time of the operation was so short, and the patient was so easily anæsthetized, that she could not have taken a large quantity. At no time during the operation was she profoundly anæsthetized. There was no stertorous respiration or even momentary stoppage of respiration. Dr. Hirons saw her two or three times after she was placed in bed, and was impressed with the rapidity with which she recovered from the influence of the ether, as well as with her normal respiration and normal, full pulse. Although she complained of pain, it was not of marked severity. A half-hour later, he was summoned to her room and found her suffering severe pain in the perineum in the locality of the sutures, as is commonly felt after such operations, and more especially in patients who are rather obese. She stated, upon inquiry, that she had never taken morphia or opium in any form. She was perfectly rational, conversed freely, and manifested no signs whatever of lingering anæsthesia; but was in excellent condition. Dr. Hirons then administered by hypodermic injection a quarter of a grain of morphia, dissolving the powder in fresh water, adding a ninety-sixth of a grain of atropia. In filling the syringe, a few drops of the solution were lost, so that he remarked that it would probably be necessary to repeat the dose in a few hours. In twenty minutes she ceased to complain of her pain, and for an hour conversed cheerfully with her friends. An hour and a half later, he was summoned to her room, and found the patient in an unconscious condition, so profound that he could not arouse her. Her breathing was difficult and shallow; her pulse was rapid but weak; her skin was cold and moist; the pupils closely contracted, and it was apparent that she was suffering from opium narcosis. Cold water was dashed upon the face, heat was applied to the extremities; the one-ninety-sixth grain of atropia was administered hypodermically, and all the usual methods were applied to resuscitate her. At the same time Dr. Reamy was summoned. When he arrived half an hour later, the patient was in about the condition described. Another dose of one-ninety-sixth of a grain of atropia was administered hypodermically. Coffee was given by enema; ammonia and brandy were repeatedly administered subcutaneously; mustard was applied to the chest and abdomen, and every effort was made by heat and frictions to the extremities, flagellations, etc., to arouse consciousness, but without success. The faradic current was applied, one pole being placed over the region of the phrenic and pneumogastric nerves, the other over the diaphragm. This for a time seemed to improve the breathing and the pulsations of the heart, but only for a time. Artificial respiration was now resorted to and persisted in until the heart had ceased to beat. As the pupils had not responded to the atropia already administered, another dose of the $\frac{1}{120}$th of a grain was given. All remedies failed, however, and death occurred eight and a half hours after the first administration of morphia, supervening upon a state of profound coma, the action of the heart becoming gradually more feeble, the breathing constantly becoming slower, until it amounted to only four or five respirations per minute.

DR. S. NICKLES remarked that, while very serious symptoms have been known to follow the administration of even less than a quarter of a grain of morphia, the case just reported was the first, so far as he was aware, in which the death of a healthy adult resulted from so small a dose. According to Husemann (*Die Pflanzenstoffe*, 2d edition, 1884), the smallest dose which has caused death was one grain. This had been given to a girl, aged nineteen years, in divided doses, within six hours. Death resulted in thirteen hours. Husemann also refers to a case, reported by Taylor, in which half a grain was supposed to have destroyed an unhealthy patient, but considers it a doubtful case. Not infrequently, after hypodermatic injection of small doses, there takes place sudden prostration, with marked giddiness and very difficult breathing. From the rapidity of action, it is inferred that the medicine was thrown into a blood-vessel, for it is now well established that such effects take place in a few seconds after intravenous injections.

The case reported by Professor Reamy was a doubt-

ful one. The patient died eight hours after the subcutaneous injection of a quarter grain of morphia with such symptoms as are usually produced by large or toxic doses. Administered subcutaneously, morphia produces its characteristic action upon the cerebrum in from five to twenty minutes. But in the case reported the narcotism did not take place before the lapse of an hour. Then the patient became comatose, the pupils contracted strongly, the respiratory movements became slow and shallow, and the pulse rapid and feeble. Notwithstanding the use of the various means usually resorted to in morphia poisoning, the patient succumbed in about eight hours. No post-mortem examination was made, and hence, to say the least, the case is a very doubtful one. It is not unlikely that a post-mortem examination would have revealed a cerebral hemorrhage.

However, if the case be considered one of medicinal poisoning, by so small a dose as a quarter of a grain of morphia, it will show that such a dose, administered subcutaneously to a patient unaccustomed to the action of morphia, is not a safe one. Some authors insist that the first hypodermatic dose shall not exceed one-sixth of a grain.

The case is certainly a remarkable one, in so far as death resulted, notwithstanding that the patient, a healthy, strong woman, was seen soon after narcosis began, and was at once placed under treatment. At no time did the measures employed diminish the coma, increase the respirations, augment the force of the pulse, or otherwise alter the symptoms which were supposed to be due to the quarter grain of morphia. This negative result of the prolonged efforts to save the patient is sufficient to justify the opinion that there was present some other cause of the coma. Usually, in poisoning by lethal doses of morphia or opium, the antidotal and antagonistic treatment, for a time at least, produces very obvious amelioration of the symptoms. And when these measures are efficiently employed, they usually rapidly improve the symptoms and save the life, even when many times the lethal dose has been given.

Morphia and opium poisoning being so frequent, the speaker thought it proper to make a few remarks on the treatment. Generally the poison is taken *per os*. In such cases the first indication is the removal of the contents of the stomach. Morphia is slowly absorbed, and, even after the lapse of hours, sufficient may remain in the stomach to destroy the patient. If the patient be seen early, before coma has taken place, means to excite vomiting are proper. Irritant emetics, especially sulphate of zinc and sulphate of copper, may be employed. But these emetics should be used in the ordinary doses, and not in quantities of half a drachm, as recommended by some authors. If the stomach is insusceptible to the action of several ten-grain doses of sulphate of zinc, larger doses will prove equally inactive. Absorption of the salt will occur, and the depressing effect of the morphia will be increased. Even when the stomach is not benumbed by a narcotic, moderate doses of sulphate of zinc more certainly produce the emetic effect than large doses. Toulmouche observed that doses of from six to twelve grains constantly cause vomiting, while doses of fifteen grains or more constantly failed to have this effect, while they generally produced purging. The vomiting process may be hastened by titillation of the fauces and the administration of large quantities of tepid water. As an antidote, tannic acid should be given; it will render the morphia less soluble, or, if the latter be in solution, will form with it a salt which is less readily absorbed. From twenty to forty grains of tannin will usually suffice.

Partly as an antidote, and partly as an antagonist, strong infusion of coffee should be given. Its tannic acid will retard the absorption of the morphia, while its active principle—the caffeine—will antagonize the general action of the poison by stimulating respiration, augmenting circulation, and elevating the temperature. If the patient be comatose, vomiting cannot be induced. Then the stomach-pump should be employed to evacuate the contents of the stomach. Instead of water, it will be prudent to employ an infusion of coffee to wash out the stomach.

The second indication when the poison was ingested, and the only one when it was thrown into the subcutaneous tissue, is stimulation of the central nervous system, especially the respiratory centre. Various measures are recommended, as flagellation, friction of the surface, ambulation, painful applications of the faradic current, and douches of cold water. When the patient has not yet become comatose, these measures are often useful, but usually completely fail, after profound coma and great prostration have taken place. Liebermeister reported a case of severe morphia poisoning in which the douche of cold water, applied at intervals of ten or fifteen minutes for six hours, proved successful. At the same time, however, the patient was kept in a warm bath. Perhaps the latter measure had much to do with the recovery, for heat is a powerful stimulant of the respiratory centre and the heart. During profound morphia narcosis the temperature of the body falls several degrees. Hence, the patient's room should be kept warm, the patient should be covered with warm blankets, and bottles containing warm water or heated bricks should be applied to his extremities. Frequently all these measures fail to increase the respiratory process and the heart's action. Then recourse must be had to the most powerful means of stimulating these functions—namely, artificial respiration and subcutaneous injections of atropine.

Various methods of practising artificial respiration have been recommended. Schüller succeeded in two cases with the following simple method: Applying his hands along the thorax, from above downward, he grasped the right and left borders of the chest and forcibly drew the ribs outward and upward, and then quickly pressed them back towards the abdominal cavity. These movements were repeated rhythmically, so as to correspond to the normal respiratory movements. An assistant at the same time maintained complete flexion of the thighs in order to relax the abdominal parietes. In order to restore the normal frequency of the respirations, the faradic current has been strongly recommended. The electrodes are applied in such a manner as to cause the current to pass through the phrenic nerve—first on one side, and, after an interval, on the other. This may be accomplished by firmly applying one electrode just behind and below the middle of the posterior border of the sterno-cleido-mastoid muscle, and the other electrode in the supra-

clavicular space. As soon as the diaphragm has contracted, one of the electrodes should be removed, and the abdominal surface should be compressed in order to promote expiration. After a few seconds the current should again be applied, and this be followed by abdominal compression. The application of the current should be repeated about fifteen times in a minute.

Recourse should also be had to atropine. Its utility consists not in a complete antagonism to morphia, but in an antagonistic action of the respiratory centre and heart. Hence the condition of the respiratory and circulatory functions is the index to the use of atropine. Abnormal slowness of the respiratory process and feebleness of the pulse indicate its use. According to the reports of good observers (Johnson, Binz, Robert, Fothergill), soon after the hypodermatic injection of atropine, the respirations become accelerated and the pulse stronger, How much atropine should be injected? Evidently this will depend on the condition of the functions to be excited, and the effect of the first moderate dose. Some authors recommend the small dose of the fortieth of a grain. If the respirations should become increased in frequency, a few repetitions of this dose may suffice; but should no effect have taken place in ten or fifteen minutes, the next dose should be larger—say one-twentieth or even one-tenth of a grain. Johnson, who had perhaps greater experience in the treatment of opium poisoning than any other physician, having treated more than three hundred cases, employed large doses, from one-third to one-half of a grain. According to him, the cold douche, artificial respiration, the application of electricity, and all kinds of stimulation are usually of no utility, while the administration of atropine is speedily followed by wonderful effects, the pulse becoming stronger, the respirations more rapid and tranquil, and the coma a peaceful slumber, from which in a few hours the patient awakens fully conscious.

DR. P. ZENNER remarked that it seemed to him that atropia had been rather too freely administered, since atropia antagonizes the action of morphia on the heart, as well as on the respiration, and in this case the heart's action was too rapid, instead of too slow. Was it not possible, then, that the atropia only exaggerated the injury already done to the heart? In regard to the application of electricity in cases of this character, he had no faith in the efficiency of the remedy further than the action it had in stimulating the peripheral centres, and through them acting on the circulation, the impulse being finally carried to the heart. He thought that the best method was to apply a strong current to the skin by means of the electric brush.

DR. J. T. WHITTAKER, in renewing the discussion, said that the Academy was to be congratulated in having received so faithful a report of a case that had turned out so unfavorably. He also congratulated the reporters of the case for having had the courage to present a report of this kind. If all the cases of mysterious death were reported to medical bodies, the profession would be benefited rather than suffer.

The most powerful weapon that we have, the "*magnum donum Dei*," has been assailed in this case. We might feel the consternation of soldiers who learned that their chief weapons were dangerous to themselves. When a case of this kind occurs, we want to be entirely sure of the accuracy of the reported facts; exactly how much morphia was given, how it was given, under what circumstances. We must question the competency and the credibility of the witnesses. In this case he was personally acquainted with the physician who administered the drug, and he knew him to be perfectly competent and trustworthy, inasmuch as he had been for a year his assistant at the hospital. The physician administered the morphia from a powder of known quantity, freshly dissolved in a spoon—a practice which it is probable he had learned from the speaker, for that is the method he employs and teaches. The atropia must necessarily have been added from a solution to the powder. The speaker expressed a desire to know how the powder appeared to the physician as he dissolved it, whether it appeared large or small; whether it was in crystal or in fine powder, for a given quantity pulverized appears not more than a quarter or a sixth as large as the same quantity in crystals. A mistake might have been made in this way, for we are all familiar with the manner in which druggists divide their powders. It is stated in this case, on the authority of several witnesses, that the druggist was cautious and careful. The question next arises, Did the accident occur on account of the morphia alone, or were there other agencies that influenced the result? We must consider, first, the operation; second, the ether; third, the atropia; fourth, the possibility of compression from cerebral hemorrhage, and, fifth, the possibility of the formation of a thrombus. All these questions would have to be discussed if the case were brought up before a court of justice.

The operation was a trivial one, and the patient appeared to recover perfectly. She recovered properly also from the ether. Had the anæsthetic used been chloroform, we would have had to consider the possibility of a collapse even some time after recovery, but with ether this is not the case. It would be barely possible to have such a result from ether.

The ninety-sixth of a grain of atropia could not possibly have done fatal harm. The smallest dose of this drug that the speaker knew of having caused a fatal result was two grains. There remained only the question of apoplexy, thrombus, and morphia. The patient was too young for cerebral hemorrhage, and she had no heart disease to account for an embolus. Very vague ideas, he said, prevail regarding the formation of a clot, a thrombus. It appears to be generally believed that all that is necessary to the formation of a clot is to have the circulation stopped. That is not true. Blood coagulates in a vessel in which the endothelial covering of the internal coat of the vessel has been broken up or diseased in some way. There is nothing that so quickly causes disease of the endothelium as septic poison. There was, however, nothing in the case under discussion that could have produced an injury of the endothelium. There was no infectious process. There was no inanition, no marasmus to have impaired the vitality of the endothelium. Moreover, the signs of morphia poisoning were present in the individual. The pupils were contracted; the face was suffused and cyanotic. As stated by a previous speaker, morphia kills by attacking the respiratory centres of the brain; when an individual dies by morphia, he dies asphyxiated. There was the additional fact in this case that the res-

pirations were reduced to six per minute, though the rapidity of the heart was increased, contrary to the rule. He differed from one of the previous speakers in his statement that morphia has no action upon the heart. According to the experiments of Witkovski, toxic doses diminish very decidedly the frequency of the heart. There were formerly different opinions expressed in regard to its action on the eye. In the celebrated Castaign case, Orfila declared that morphia always contracted the pupils, while Chaussier maintained that it sometimes dilates them. Now, however, we know that it at first contracts them, and that as soon as the stage of asphyxia comes on, the pupils often dilate. Mistakes have been made by physicians who saw cases only after some time, and observed only the dilated condition of the pupils.

In regard to the amount of morphine that will produce a fatal result, the speaker said that Taylor, in his *Jurisprudence*, reports that five cases are on record in which death was produced by a single grain; but a large number of cases have been reported in which the equivalent of less than one grain has caused death. A drachm of the tincture of opium is the smallest amount of this preparation that has produced death in the adult.

Opium poisoning is the most common of all. In England, from 1837 and 1838, there were 527 cases of poisoning, and, of these, 198 were by opiates, while of arsenic there were but 185. Guy, in his report for 1852–56, says that half the cases of poisoning in these years in England were from opiates.

Galtier reports eighty-three fatal cases of poisoning in New York in 1880–83, of which thirty-nine were by opium. In recent years opium poisonings continue to increase.

It is more important for us to know that the great majority of the cases of opium poisoning are not the result of intention—that is, suicidal—but are accidental medical cases.

In all cases it is necessary to consider the question of age, of habit, of circumstances and condition. The question of age could not enter in this case; neither need the question of habit be considered. The danger of opium in early life has been thoroughly discussed. The most significant fact is the statement made by Guy that over two-thirds of the fatal cases are children under the age of five. This patient had no opium habit. The tolerance to opium is something wonderful, but the opiophage constitute a respectable contingent of the fatal cases. They resume it in large doses after having ceased to take it for a time, and fall easy victims to its toxic effects.

Husemann reports the case of a woman with cancer who took twenty grains a day; Credé a case in which fifty-two grains was the daily dose. Albin Eder's preacher took at least forty-five grains of morphia a day. Otis reports a patient who injected, hypodermatically at a single dose, sixteen grains; Burkhardt a case in which thirty grains were injected; and the speaker had a patient who used hypodermatically twelve grains at a time, usually repeating the dose three times daily. It is not infrequently that accidents supervene in these cases, for the individual having, to a great extent, broken off the habit, or reduced the quantity, returns to it, and is unable to endure the larger dose.

He agreed with a former speaker in his statement that morphia has the same effect whether taken hypodermatically or by the stomach. The only difference is in regard to time. Husemann states decidedly that there is no proof that morphia acts any more powerfully hypodermatically than by the stomach, but that it is only more prompt. If all the morphia be absorbed from the stomach, the effect is the same. As a rule, it is all absorbed, and the same effect is soon produced as when taken by the stomach.

On the other hand, there are individuals who cannot take opium at all without danger. In other words, there is an opium idiosyncrasy. We know that some people require twice as much as others to produce sleep under the same circumstances.

In regard to this inability of some persons to take morphia, he referred to the case of deep narcosis reported by Christison after seven drops of the tincture, and related a case that he had himself seen, with another member of the Academy, in which, after the administration of a half grain of morphia in two doses, they were compelled to watch the patient for twenty-four hours; and a case in his own practice in which he had administered five grains of Dover's powder, notwithstanding the protestations of the patient, because he did not credit her statements, and he was compelled to watch with her all night. Viber had a case that was poisoned by two milligrammes—about the thirtieth of a grain. Fortunately, he remarked, such cases are so extremely rare, that the accuracy of the statement is always questioned.

Referring to the statement that the patient did not exhibit signs of intoxication until an hour and a half after the dose had been administered, he said that there was nothing remarkable in the fact. It is not at all uncommon for the remedy to act in this manner.

Christison reports a case in which ten hours intervened between the ingestion of an ounce and a half of laudanum and the narcotic effects. Taylor mentions a case of interval of three hours, during which time the individual walked the room, and another case of an individual who, after taking half an ounce, talked two hours with a neighbor before the toxic effects supervened. Moore's patient walked about one hour and a half after the enormous dose of seventy-five grains of morphia. More numerous and more dangerous are the so-called cases of secondary asphyxia, in which the patients recover, and die in twenty-four to forty-eight hours of a relapse. Such phenomena are explained upon the assumption that the remedy is not at all or not all absorbed for some time.

In conclusion, he stated his belief that the case reported had been a clear case of morphia poisoning, and, as for the treatment, he thought all had been done that was justifiable, unless it had been a bolder use of atropia.

Were he called upon to treat a case of poisoning by the hypodermic use of morphia, he thought that he would give not less than a tenth of a grain, and, if this did not have the desired effect, he would repeat it until a half or even a grain had been given. All the measures used are with a view to stimulate the respiratory centres until the morphia is let loose from its combination with the protoplasm of the nerve cells. Crecy had a good result in one case from the inhalation of

oxygen, a treatment in scientific accord with the indication in a case. Unfortunately, the treatment is not practicable in most cases, and we must reply upon coffee, flagellation, faradization, artificial respiration, and atropia.

DR. P. S. CONNER remarked that the case under consideration was of more interest to surgeons than to those engaged in medical practice, for morphia is the strongest support of the surgeon. He would feel exceedingly sorry if the report of a single case or any number of cases of death from so small a dose should lessen the confidence that we have in the remedy. He agreed perfectly with the last speaker in attributing the death to an idiosyncrasy. The patient was not able to tolerate an ordinary dose. The question of idiosyncrasy is an exceedingly interesting one. Every one has peculiarities at one time that he has not at another. This is true not only of opium, but of very many other drugs. Vincent, of Lyons, has recently reported experiments upon animals, in which drugs were administered by intravenous injection, and the most varied idiosyncrasies were observed. The most extraordinary differences were observed in different animals under the same conditions, and in the same animal at different times. The speaker referred to the enormous doses that are sometimes tolerated by individuals who are not accustomed to the use of opium, and instanced the case of an army associate whom he knew not to be accustomed to it, and yet took five grains of morphine with no effect more than to secure him a night's relief from severe pain.

That death should result from so small a dose he considered remarkable, but he thought that such a case should not influence our faith in the use of the remedy. In regard to the use of atropia, he thought that it might have been more freely administered, because it is generally so well borne. He remembered a case in which he had given an eighth of a grain to an individual in three doses, and where it was very difficult to satisfy the "intelligent" jury who sat on the case that the death was the result of hydrophobia, and not the result of atropia. So, while it was very easy to look back and say that a larger amount might have been given, it would have been much more difficult to determine the question at the bedside of the patient; and he had no doubt that if a grain, or even half a grain, had been administered, there would have been more than one ready to attribute the death to the atropia instead of to the morphia, and it would have been said more than once that the individual would have gotten well easily enough had not the atropia been given.

In regard to the use of electricity, he said that nearly every report that one reads of a patient being overcome by chloroform or any of the narcotics, states that the battery had been used to stimulate the pnemogastric. In his opinion, nothing worse could be done: since the pneumogastric was the inhibitory nerve of the heart, and its stimulation would only add to the existing trouble. He agreed with a previous speaker who thought that electricity was of service by its stimulation of the skin. It was all the more surprising that so small a dose of morphine should result fatally after an operation, for it is a well-known fact that individuals who have been the subjects of operations generally bear morphia better than those who have not been operated upon. It is customary to give not a quarter of a grain, but a third, a half, or even a full grain after an operation; such had been his practice, and he had never had any evil result from it. This individual was unfortunate in that she had an idiosyncrasy; and the reporter might, changing the words of Paré, say, "I dressed her, and God (not cured, but) killed her."

DR. S. NICKLES stated that nearly all authors who discuss the measures appropriate in morphia poisoning recommend the application of electricity to increase the frequency of respiration. They do not, however, direct that the current shall be passed through the pneumogastric nerve, which would retard the heart's action, but only through the phrenic. The question of importance to us is, Will the electric current properly applied increase the depth and frequency of the respirations? for this is the most important indication in all cases of morphia poisoning. That the faradic current passed through the phrenic nerves in persons whose respiration is failing from narcotic poisoning, will cause very active contraction of the diaphragm has been repeatedly observed. A case treated by the speaker a short time ago demonstrated the power of electricity. The patient was found in profound coma, with slow stertorous breathing, and cold, moist, cyanotic skin. After a prolonged spree, he had taken bromide of potassium, chloral, chloroform, and morphia. The faradic current was passed through the phrenic nerve, and produced deep inspirations. The respirations were thus maintained at fourteen in the minute for several hours.

In Dr. Reamy's case, no such effects were obtained. This, as well as the supervention of the coma, renders the case a very doubtful one. Cases of supposed opium poisoning had been reported, the patients having taken lethal doses of the narcotic, in which post-mortem examination revealed cerebral hemorrhage. Johnson had reported several cases. He did not believe that in a healthy adult between the ages of twenty and fifty years there could exist so strong an idiosyncrasy that a quarter of a grain would produce death. The smallest dose of opium known to have destroyed an adult was four grains. The best opium may contain as much as twenty per cent. of morphia, and three grains may be considered equivalent in therapeutic activity to one grain of morphia. Opium, however, contains besides morphia a large number of alkaloids, although in smaller quantity.

He said that no antagonism exists in the action of morphia and atropia on the pupil. When atropia is instilled into the eye, rapid dilatation of the pupil ensues; a similar application of morphia produces no effect. In the one case the remedy, atropia, acts upon the peripheral part of the oculo-motor nerve; in the other, no action whatever takes place. How morphia produces myosis is still unknown, except that it is due to a central influence. The fact alluded to by a previous speaker that atropine will dilate the pupil contracted by morphine proves nothing, since morphine applied locally will not contract the pupil dilated by atropine.

A previous speaker referred to the experiments of Witkovski, as proving that therapeutic doses of morphia do affect the heart's action. The experiments of Witkovski were performed on animals. The action of morphia on different species of animals differs widely; it differs still more between man and all species of animals. Hence, no conclusions can be drawn, as to

the action of morphia upon man, from the effects observed in animals. But Witkovski did not conclude that morphia markedly affects the circulation. On the contrary, in the summary of the results (*vide Archiv f. exp. Pharm. und Path.* Bd. vii. p. 268), he says: "The centres of the inhibitory vagus fibres of the vasomotor nerves, and the contraction of the pupil, are not directly influenced by morphia, either in the form of paralysis or excitation," and "the heart itself is not influenced."

Experiments of real value were performed on healthy men by Riegel and Priesendörfer. They administered from a sixth to a half grain of morphia to healthy adults. In no instance did they notice any variation in the force or frequency of the heart's action, and hence they conclude that "morphia, in doses of from one to three decigrammes (one-sixth to one-half grain), exerts no action upon the vascular system of man."

Toxic doses, on the contrary, do affect the circulation, the pulse becoming feeble, slow, and irregular. The slowing of the heart's action is attributed to the excitation of the inhibitory nerve of the heart. But the slowing persists when the inhibitory centre has become paralyzed, in consequence, it is supposed, of paralysis of the musculo-motor ganglia of the heart.

The action of morphia, introduced hypodermically, differs from the action by the stomach chiefly in quantity and rapidity, not in quality. It is quickly absorbed by the subcutaneous lymphatics, and hence acts in a few minutes. But from the stomach, absorption takes place slowly, and often incompletely. Morphia has been detected in the human stomach fifteen hours after the administration of small doses. It has been discovered in the small intestine of the cat from fifteen to eighteen hours after administration. Sometimes, after the therapeutic use of morphia, it is not completely absorbed, since small quantities have been detected in the feces.

Morphia is not rapidly eliminated, from ten to twenty hours elapsing before it, or the products of its oxidation, have entirely disappeared from the urine.

That morphia diminishes the secretions, is usually held. But there is no positive proof that it directly diminishes any secretions, except those of the mouth and trachea. After very minute doses, the salivary secretion may increase, but the mouth becomes dry after large doses. Rossbach found, in experiments on animals, that the secretion of the trachea is rapidly diminished. It is often asserted that the secretions of the stomach, intestines, and liver are diminished. This is inferred from the anorexia, indigestion, and constipation resulting from large doses, and often from small ones. Rutherford, in his experiments, could detect, after the use of morphia, no difference in the quantity of bile secreted. The constipation has been shown by Nothnagel to be produced by arrest of peristalsis, in consequence of excitation of the inhibitory fibres of the splanchnic nerves. The difficult micturition is ascribable to modification of the innervation of the urinary bladder, not to changes in the quantity of urine. The secretion of the skin usually becomes increased; and when this occurs to a marked degree, the urinary secretion becomes lessened indirectly. Toxic doses of morphia, which greatly reduce the blood-pressure, will rapidly diminish all the secretions, because these cannot take place when the blood-supply is insufficient.

DR. REAMY, in concluding the discussion, said that the most striking point in the case was the first startling announcement that the woman had suffered the symptoms stated from the exceedingly small dose of a quarter of a grain.

The woman was perfectly healthy, so far as the most careful examination could determine. She had willingly submitted herself to an operation that could not be considered absolutely necessary; notwithstanding, he regarded it as warranted for the relief which would follow. He had assured her that there was no danger in the operation itself. She was young and of high social connection, and the mother of one child.

When he saw the case, it was after the second administration of a ninety-sixth of a grain of atropia, including the amount first given with the morphia. A third dose of the same amount was then administered. It was with a full knowledge and appreciation of the fact that atropia was given for the relief of the respiratory centres; but the attendants were also aware that the books, as well as his experience, taught that the action of the heart was also influenced by it. Since the heart was already acting with abnormal rapidity, and the quantity of morphia had been so small, it was feared that any more atropia might further stimulate the cardiac ganglia and paralyze the inhibitory pneumogastric nerve, thus rendering the difficulty more pronounced. All these things were considered, as well as the question asked by one of the speakers, namely, was there nothing else that could produce this condition? After the third dose of a ninety-sixth of a grain had been given, the pupils responded to a slight degree. He was aware that the condition of the pupils was no guide to the effect being produced upon the respiratory or cardiac centres by the atropia, and that, as a rule, the remedy ought to be continued until it showed some effect on the respiration. But in this connection, he felt that it was necessary to take into consideration also the amount of morphia he was endeavoring to counteract. Did the respiratory centre need stimulation on account of the effect of morphia poisoning? Finally, it was decided to give another dose of $\frac{1}{120}$th of a grain. He had felt that they would not be justified in giving more, lest they might substitute belladonna for opium narcosis, and only further paralyze the centres they desired to relieve. The danger of this, he said, was strongly insisted upon by Bartholow (*Therapeutics*, fifth edition, page 519), where he says, that "Belladonna in too great quantity, or too long inaction, exhausts the irritability of the unstriped muscular fibre, and thus induces the very state which its administration is intended to relieve," etc. This view is also concurred in by other high authorities.

While the amount of atropia that had been administered was not enough to prove at all dangerous to life, there were other things to retain him from giving more. One of these was the possibility, not yet positively eliminated, of the case being one of apoplexy. Still he regarded this at the time as an improbable condition, from the absolute equality in the degree of contraction of the pupils. Then, too, he agreed with the speaker who had remarked that if he had given more, it would have been said that the patient died from bad

therapy, rather than from the effects of opium. He must insist that, sustained by the highest authorities, as well as his own judgment, *he was bound, in determining the quantity of atropia, to consider the quantity of morphia which had been given, as well as the character of the heart's action.*

In regard to the faradic current, attention was called to the fact that it was applied over the course of the phrenic more diligently than to the pneumogastric.

Speaking of the amount of morphia that may prove fatal, the speaker referred to Wood's *Therapeutics*, third edition, page 125, where it is stated that the smallest dose that has proved fatal in the adult was the sixth of a grain, administered hypodermically. In a foot-note on the same page, the statement is made that the literature now presents many similar cases. Although we do not know the nature of the condition we call an idiosyncrasy, he thought it strictly correct to attribute the accident he had reported to such a condition, rather than to state that, because the dose had been so small, it must have been due to some other trouble.

In conclusion, he narrated a case that had occurred in his practice a number of years ago. He was called one evening, just as he was starting to attend an obstetrical case, to see a patient to whom he had been accustomed to administer morphia subcutaneously, in the dose of a quarter of a grain, at intervals of two or three weeks, for the relief of a severe neuralgia. At that time, he was in the habit of keeping his morphia for hypodermic use in a solution which he always had prepared by the same pharmacist, and in the same quantity. When he arrived at the home of the patient, and was about to prepare the usual dose, he discovered that the greater part of his solution had escaped, so that there was not enough to give the usual amount. Being pressed for time, he clandestinely filled the bottle with water, diluting the remaining solution at least ten times. From this, he administered the usual quantity, intending to return in a short time and repeat the administration with a stronger solution. When he returned, about two hours later, he found the patient in a coma, with another physician in attendance, and both were required to remain all night in order to restore her. The woman died suddenly a few years after, and her death was attributed to apoplexy.

RHODE ISLAND MEDICAL SOCIETY.

Semi-Annual Meeting, December 18, 1884.

THE PRESIDENT, DR. OLIVER C. WIGGIN, IN THE CHAIR.

(Specially reported for THE MEDICAL NEWS.)

THE PRESIDENT addressed the Society in behalf of the

ESTABLISHMENT OF AN ANATOMICAL MUSEUM,

emphasizing the importance and value of such a collection, and expressing the opinion that there were young men in the Society abundantly qualified to take the initiative steps. He thought it best not to draw upon the funds of the Society for the object in question, but to meet the few incidental expenses from other sources.

Upon motion of Dr. Terry, it was voted that the Chair appoint a committee of five Fellows, to be known as the Museum Committee, with full powers to act.

The Chair constituted the Committee as follows: *Chairman*, Dr. W. J. McCaw; Drs. G. T. Swarts, T. B. Fuller, C. M. Godding, and B. R. Lymonds.

DR. EZRA DYER, of Newport, reported a case of

FISTULA OF THE ANTITRAGUS,

and said this affection was very rare. It is one that causes some annoyance. Properly described, it is not a fistula, but a minute sac situated about a centimetre above the antitragus. His patient was a young lady, fourteen years of age, who was annoyed by the offensive matter exuded from the little sac, which was a centimetre in depth. She had been treated by several New York physicians without benefit. Caustics had been employed, and the sac had been partly slit down, among other procedures. Dr. Dyer armed the point of a curved needle with hard wax, making it probe-pointed, and passed a heavy silk suture through the sac, as a seton. This was allowed to remain ten days, but did no good. Finally, a loop of platinum wire was passed into the sac and brought to a white heat by galvanism. The patient complained of a good deal of pain at the time, and the operator had not seen her since, but had been told by her father that the sac closed up entirely, and without further trouble.

DR. E. W. TENNEY reported a case of

RETAINED PLACENTA.

The woman was thirty-six years old, and had menstruated normally up to eleven months ago. Since that time she had flowed for two or three days, at intervals of two months or more. These hemorrhages, at first, were not very copious, and were painless, but had increased in severity of late. He first saw the case Dec. 10th, and found the patient flowing freely and suffering intensely. Suspecting abortion to be near at hand, she was questioned as to her condition, when she denied that she was pregnant at all, and, upon further inquiry and examination, he decided that probably she was not so. The mammæ were soft and flabby, and the uterus little if any enlarged. Digital examination revealed a fleshy mass occluding the os internum, which was then thought to be a pediculated fibroid which the uterus was trying to expel. Morphine was given hypodermically to relieve the pain. The next day the mass was found crowded lower down in the vagina, and was extracted without much difficulty. It proved to be a placenta about two and a half inches in diameter and studded with pea-sized cysts filled with clear fluid. Evidently hydatiform degeneration had occurred.

It was the opinion of the writer that pregnancy began eleven months previous, and that the placenta had been retained that length of time—a very rare occurrence, so far as he could learn.

THE PRESIDENT remarked that he had not supposed such cases were so rare, and mentioned two from his own practice. In the first case the placenta was retained in the uterus for eighteen months, and had become contracted into a round, fibroid mass, and nided, as it were, in a sac on one side of the fundus, making a ball the size of a walnut. Dr. Wiggin introduced his finger and released the round mass from its enveloping sac, leaving it free within the cavity of the womb, from which he did not attempt to remove it. A dose of ergot was given, which was followed, within twenty-four hours, by the expulsion of the placental mass. In the

second case, on delivering a child at full term, he was surprised to find in the uterine cavity an old placenta, which had been retained there since the occurrence of an abortion some time previous to this pregnancy.

DR. D. H. BATCHELDER remarked that he had a patient now under observation who has a retained placenta from an abortion that occurred three months ago, because she refused to have it removed by his method. It was his belief that the advice of some authors to leave the expulsion of the placenta to nature, in cases of abortion, was wrong, and that it should be accomplished without delay. His own method was to introduce a home-made instrument, viz., a piece of large-sized wire bent into the form of a ring. He would turn this, in the uterine cavity, with considerable force, so as completely to break up the placenta, which was sure to be expelled within twenty-four hours without serious hemorrhage or other bad results.

DR. F. B. FULLER then read a paper on

THE NATURE AND PREVENTION OF PUERPERAL FEVER.

The various theories of eminent authorities, as to the nature of the disease, were carefully reviewed. The writer claimed that the connection between zymotic causes and puerperal disease is too close to be overlooked, and, in the way of prevention, it is the physician's duty to see that the most perfect ventilation possible is maintained in the lying-in room. The invasion of the genital tract by germs before labor is to be guarded against by cleanliness and the use of antiseptics. After delivery the firm contraction of the womb is a most important condition in the prevention of puerperal fever. To insure this, pressure over the fundus is to be kept up for some time by the hand and then by a binder, together with the administration of ergot and opium. All lacerations of the perineum should be stitched. The bed should be kept clean and its linen frequently changed. The napkins should also be frequently renewed and disinfectants used.

DR. TERRY remarked that he believed puerperal fever to be of septic origin and nature, and not zymotic at all; even though it may occur before labor, and in waves, as it were. When we have no cases of puerperal fever, we get careless, and doors are left open, inviting septicæmia. He also alluded to the connection between offensive lochia and septicæmia, and said it was a common thing, when he was in the lying-in hospital, for the lochia to be offensive, but that he had seen only four instances of it in his private practice, three of which occurred in one week—just following the case of a patient who died of self-induced abortion and septicæmia. He thought he himself carried the disease germs from this case to the other three.

He also thought we have in milk fever, so called, a mild form of septicæmia. In the lying-in hospital the patient's temperature was very apt to be from 101° to 103° on the third day after confinement, but this is not the case in private practice.

DR. NEWHALL claimed that we possess no certain knowledge of germs as the cause of puerperal disease, and that the question is still unsettled.

DR. TERRY remarked that he supposed no one claimed, as yet, that the germ theory is anything more than a theory, but it is found that treatment based on that theory is the most successful.

DR. BATCHELDER said that he had attended about three thousand confinements, and had seen only four cases of puerperal fever among the entire number.

DR. FULLER said that he was glad some of the speakers had been fortunate enough to have so few cases of puerperal septicæmia in the long series of cases mentioned, but statistics showed that in New York City during one year, one death out of every one hundred and twenty-seven had been caused by that disease. If we could all live as the primitive man lived, we would need no antiseptics and hear of no puerperal fever. To acknowledge the identity of septicæmia and puerperal fever is not necessarily to accept the germ theory. The existence of septicæmia is undoubted, and hence we should take all possible precautions against it.

DR. CASWELL thought that septicæmia is liable to occur after confinement, when the cervix or perineum has been lacerated and neglected, or when the medical attendant has recently come from a case of erysipelas or septicæmia or a post-mortem, and has not observed the proper rules for cleansing and disinfecting himself. He did not think we were expected to follow *all* the directions set forth by Dr. Thomas, but there was surely a middle ground we could occupy with safety. In ordinary cases he would do away with much that Dr. Thomas has advised, but in times of epidemics or under unfavorable circumstances every precaution should be observed.

DR. ELY also believed a middle course to be the best. Absolute cleanliness is the important element. There was no doubt as to the great value of intrauterine injections in certain cases, but he inclined to the belief that the good accomplished was not so much due to the potency of the fluid injected as a *germ destroyer* as to its effect simply in rinsing and washing out the uterine cavity, and thus freeing it mechanically from decaying matter and germs. Probably the injection of *pure* water would accomplish as much. It certainly is the duty of every physician to free himself from dangerous contamination before approaching a case of parturition.

DR. CHARLES O'LEARY expressed his concurrence in the remarks of Dr. Caswell, and said he believed that too much meddling in midwifery was injurious.

Upon motion of DR. CASWELL it was voted that

THE ANNUAL MEETING

of the Society be held on the *second* Thursday of June instead of the *third* Thursday as heretofore.

DR. CASWELL reported a

CASE OF LITHOLAPAXY.

About two years ago he first operated on the patient, removing a small stone intact, and the fragments of a second one. The cure was complete until symptoms of stone reappeared a few months ago. On December 2d, he operated again with exactly the same result, viz., the removal of a small stone unbroken and the fragments of a slightly larger one which could not enter the tube intact. The recovery of the patient was rapid, he being about the house the following day, and at his place of business on the third day. Dr. Caswell alluded to this illustration of the immense advantage of the crushing over the cutting operation in case of a small calculus.

DR. G. T. SWARTS then read a long and interesting

paper, giving the statistical and other conclusions based on his personal investigation of three hundred out of the five hundred cases of

TYPHOID FEVER

reported to the Superintendent of Health in Providence, during the epidemic of 1882 and 1883. The special object of the investigations had been the causation of the disease.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Stated Meeting, December 5, 1884.

(Specially reported for The Medical News.)

The President, T. G. Roddick, M.D., in the Chair.

The President exhibited a

TUMOR OF THE BLADDER

about the size of a hen's egg, which he had successfully removed from a patient under his care in the General Hospital. A microscopic slide of the tumor was also presented, which showed that it was a cystic papilloma.

The history of the case is as follows: Patient, aged fifty-three, ten years ago first noticed difficulty of micturition, three years ago passed blood with his urine; at that time he was making water every hour; this was preceded by pain, referred to the end of the penis and neck of the bladder. Since then he has been troubled with frequent and painful micturition, for relief of which he applied for admission to the Hospital. When admitted into the Hospital he was making water every hour, but from a bladder so distended that it reached nearly to the level of the umbilicus. He complained of great pain in the left iliac region, especially during the act of micturition. The prostate, on examination, proved to be only very slightly larger than normal. The bladder was sounded carefully, but nothing definite could be made out. Dr. Roddick, thinking the case was either one of encysted stone or tumor, determined to explore the bladder after the manner recommended by Sir Henry Thompson. This he did on November 12th. A staff was introduced and the perineum incised in the middle line and the urethra opened in the membranous portion; the finger was then introduced through the prostatic urethra, and almost immediately something was felt. On examining more carefully, Dr. Roddick discovered a pedunculated tumor attached to the side of the neck of the bladder; this he freed with his fingernail and extracted with forceps. For a few days the man had some elevation of temperature, but afterwards he did well, and was, at the present time, passing his urine by the urethra.

Dr. Roddick remarked that he had several times explored the bladder according to Sir Henry Thompson's method, but that this was the first time he had discovered a tumor.

CHICAGO GYNECOLOGICAL SOCIETY.

Stated Meeting, December 19, 1884.

The President, H. P. Merriman, M.D., in the Chair.

Dr. Etheridge exhibited

A PLACENTA WITH CALCAREOUS DEPOSITS.

The placenta was removed from the body of a woman, pregnant for the first time, who had probably carried the fœtus two hundred and ninety-two days. The calcareous deposit was probably the result of fatty metamorphosis of the upper layers of the *decidua serotina*.

Dr. Sawyer said that the placenta was interesting but not uncommon. It has been erroneously believed that such *placentæ* are of syphilitic origin. He thought the connection with prolonged gestation was established.

Dr. Dudley referred to the calcareous deposit in the walls of the arteries supplying an ovarian cyst which he had removed some years previously.

Dr. Jackson related the history of a case in which he had removed a mass of calcium carbonate, situated in the recto-vaginal septum, an inch and a half from the vulvo-vaginal orifice. There was no fatty metamorphosis in this case.

Dr. Earle thought there was an unreasonable tendency to ascribe such cases to the effects of syphilis. Hydatidiform degeneration of the chorionic villi and hydrops amnii received a similar erroneous etiology.

Dr. Etheridge said that the deposits were composed of the phosphate and carbonate of calcium. These salts had an affinity for albumens and fatty acids resident in the cotyledons. Similar calcareous deposits were found in fibroid, thrombi, encysted trichinæ, and in the lithopædia of extrauterine pregnancy.

Dr. W. H. Byford thought the connection between prolonged gestation and calcareous deposits in the placenta was established. He thought that Dr. Etheridge would find, on microscopical examination, that the changes had occurred exclusively within the vessel walls.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

Dr. William Darling, the eccentric Professor of Anatomy of the University Medical College, died last week of pneumonia. Prof. Darling was a man of profound learning of a limited kind, and his studious habits and retentive memory made him, without doubt, one of the best living anatomists. His room at the college, where he lived, was a perfect Golgotha, and he might have been said to live cheek by jowl with his subjects. He was exceedingly simple and penurious in his habits, and for many years walked several miles to the lower part of the city for his economical, farinaceous meals, which, for great occasions, were supplemented with a piece of meat.

The stories regarding him which have floated about the College are very entertaining, and his avidity for morbid specimens, and anxiety in regard to approaching deaths, was comical. His pathological tastes rather led him to acquire the strange and picturesque than those specimens which were of absolute scientific value. In spite of certain peculiarities, he was an agreeable, quaint old Scotchman.

The Board of Health are again in trouble, and a committee of "ladies" have prodded them into indicting one Kane, who stores vast quantities of manure on the east side of the city. This board, as well as others, has shown singular incompetence in taking care of the great nuisances of this character, and a remarkable vacillation which is not creditable.

COCAINE IN DENTAL SURGERY.—Cocaine has been used here in dental surgery, and Dr. W. Halsted has, by means of injection of a four per cent. solution (and even one of greater strength) with a curved point caused anæsthesia of the inferior dental nerves. Several operations have been performed without discomfort to the patient, and one dentist has filled teeth quite painlessly.

SCARLET FEVER.—The city is suffering from a rather decided outbreak of a very malignant form of scarlet fever.

OUR WAITING ROOMS.—Your correspondent has been impressed with the cheerlessness of many of the waiting rooms of medical men. While such places are exposed to the incursions of petty sneak-thieves, still it is possible to make them much more attractive than they now are by means of pictures and books. Illustrated and other papers several weeks old are scarcely profitable reading, and patent medicine circulars, illustrated catalogues, and such literary rubbish are scarcely calculated to engage the impatient patient. In one anteroom we found last week a large bible, bearing the imprint of the American Tract Society, was the only pabulum. When one stops to think of the diverse character of his patients, he will be a little more liberal in his provision of reading material.

CINCINNATI.

(*From our Special Correspondent.*)

MORTALITY STATISTICS.—It has always been the pride of our unprofessional Board of Health to report a lower rate of mortality at the close of each week than was reported for the corresponding week of several preceding years. The exceptionally healthy condition of the city during the last year has enabled them to accomplish this end without difficulty. But with the coming of winter the rate of mortality has very decidedly increased, so that the reports are less pleasing and, as the Board seems to think, less creditable to it than they have been for several years. In order at least partially to overcome this state of affairs, and to guard against its occurrence in the future, the Health Officer has addressed a communication to the Board, in which he recommends that the average hereafter be reckoned on a higher basis of population. Since the 1st of January, 1877, the rate of mortality has been computed upon an assumed population of 280,000. On the assumption of the Health Officer that *six* is the ratio of vote to population, the recent election would indicate that the population of Cincinnati is 353,100, or 73,100 more than the present estimate. Although the ratio six appears rather high, we are told that it is lower than the estimate made in Chicago or Cleveland. The officer very modestly recommends that on and after the 1st of January, 1885, the population, so far as the Board of Health is concerned, be considered not less than 325,000.

The report for the week ending Saturday, December 6th, indicates a total of 123 deaths, or a rate of 22.91 per annum per thousand. Deaths during the week ending December 8, 1883, 100; during the week ending December 9, 1882, 109.

YELLOW FEVER IN HAVANA.—For the week ending December 11th, Dr. D. M. Burgess, Sanitary Inspector, Marine-Hospital Service, reports only three deaths from yellow fever in Havana.

PROPHYLACTIC MEASURES AGAINST CHOLERA IN PARIS.—THE Préfecture de Police has issued the following rules, to be observed in case of an outbreak of cholera in Paris. They relate: 1, to the precautions to be taken against cholera, preventive measures, care and isolation of the patients, and disinfection; 2, to persons who have come in contact with choleraics; 3, to the certificate of death and proper burial of the dead body.

Notification. When a case of apparent cholera has come to the knowledge of a magistrate, either by communication of the physician in attendance, of the police, or by public rumor, the magistrate shall cause a special physician to see the case immediately and make a report, which shall be sent to the Chief of Police as soon as possible.

Special Physicians. In each quarter of the city, and in each ward, one or more physicians should be appointed to visit the sick persons at the first order of the administration. These physicians shall visit every case which is suspected to be cholera. They shall go to the house in which the patient is, make the diagnosis, and make out a report which must be sent to the police magistrate.

Transportation of Patients. Special vehicles have been made for the transportation of patients with choleriform affections, who cannot be cared for at home. Independently of these vehicles, others have been set apart to be used in cases of necessity. When a patient has to be carried to the hospital, the request must be made by the family to the police magistrate or to the police post of the quarter, from which place the name and address of the patient shall be telegraphed to the Chief of Police. The Chief of Police shall immediately send the ambulance, to which the horses shall be always hitched. After the transportation, the ambulance shall be washed and thoroughly disinfected. These ambulances shall be at the disposal of the public at all times, free of charge. The citizens should be advised of the existence of these special ambulances through the newspapers.

Disinfection of Contaminated Places. Disinfectants shall be furnished to the public free of charge, at all police stations; and to insure the proper execution of the prescribed measures, a special service of disinfectors has been created. These agents will immediately disinfect every place contaminated by a choleraic, either after the decease or after removal of the patient to the hospital. The disinfection is done by two persons, who shall always be ready to set out at the first call. The orders to them shall be sent by telephone. The *personnel* and the disinfecting materials are to be carried in a vehicle, which must always be ready. The number of disinfecting agents may be increased when necessary. The men shall be of age, and shall be of good moral character. The physician in charge will see that the disinfection is properly carried out.

The Burial. The police magistrates shall, as soon as possible, inform the mayor of all persons dead of cholera, so that he may at once order the burial. Special measures are to be taken that the coffins are absolutely impermeable.

Medical Service. The Mayor has been asked to organize a special Medical Service, so that families may be sure of finding physicians at certain places at any hour of the day or night.

The Chief of Police will see that ovens for the disinfection of clothing, bedding, etc., are constructed at certain places; and they shall be so made that dry or moist heat may be used, as necessary. The following are the instructions for the squads of disinfectors;

I. When a disinfecting squad is called to a room which has recently been occupied by a sick person, it shall go immediately, carrying the following articles: 1. An iron plate, two feet in diameter. 2. A bag of sand. 3. Flowers of sulpher, in packages of lb. 1¼ each. 4. Alcohol in six ounce flasks. 5. A clay furnace, or some bricks. 6. Matches. 7. Small kindling wood. 8. A metre (yard) measure. 9. A step-ladder, six feet high. 10. A pot of glue, and a brush. 11. Some paper (as newspapers). 12. Bottles of chloride of zinc.

II. Having arrived at the house, the room to be disinfected is first measured; the height being multiplied by the length, and the product by the breadth. This measure shows what quantity of sulphur is necessary for disinfecting it, ʒv being used for each cubic yard. A room of twenty-five cubic yards requires lb. 1¼ of sulphur, or one package.

Everything which has come in contact with the cholera patient should be spread on the floor, or on tables. The chimney, windows, doors, and every chink leading out of the room should be closely stopped by pasting paper over them. The furnace (or the bricks) is placed on the iron plate in the middle of the room, every precaution being taken against accident from fire, papers and inflammable material being removed from it. If a furnace is not to be had, a temporary one may be made with some bricks and sand. Into this the necessary quantity of sulphur is poured; some alcohol poured on the sulpher, so as to moisten its surface; a few bits of the kindling wood placed on, and the fire lighted. The process is similar with a furnace.

The remaining open door is then closed, and the chinks stopped from the outside; the key is given to the janitor, with instructions that no one shall enter the room. Before leaving the house, all water-closets and sinks should be disinfected with a solution of lb. 1¼ of chloride of zinc in ten quarts of water.

III. The house is to be visited on the next day, the water-closets and sinks again disinfected with the solution of chloride of zinc, the doors and windows opened, and a report made to the Chief of Police.

To complete the system of notification, the telephone companies are required to place their instruments and lines at the service of the public. Every person having a physician's certificate, showing that he wishes to use the instrument on cholera business, will have this privilege accorded him.

On November 10th, the Municipal Council of Paris voted the sum of 150,000 francs to organize the cholera service.—*Gazette Méd. de Paris*, Nov. 15, 1884.

OBITUARY RECORD.—WILLIAM DARLING, M.D., F.R.C.S., Professor of Anatomy in the Medical Department of the University of the City of New York, died in New York on Wednesday, December 24th. Dr. Darling was born in Berwickshire, Scotland, in 1815. He came to America in 1830, and in 1841 he began the study of medicine in the University in which he subsequently became a distinguished professor. In 1840 he was appointed Assistant Physician to Bellevue Hospital, and while acting as such had charge of the male and female hospitals, and of the Smallpox Hospital on Blackwell's Island. In 1845 he was appointed Demonstrator of Anatomy by Prof. Granville Sharp Pattison, which position he held until the death of Dr. Pattison, when he became Acting Professor. In 1856 he went to London, and was admitted a member of the Royal College of Surgeons. He remained abroad for ten years, most of the time in London, attending the lectures and clinics at the various hospitals. In 1866 he was appointed Professor of Anatomy in the Medical Department of the University of the City of New York, and before leaving London he obtained his Fellowship in the Royal College of Surgeons. In 1873 he was appointed Professor of Anatomy in the University of Vermont, and in 1877 he was elected Foreign Correspondent of the Société d'Anthropologie of Paris.

Dr. Darling was not a dry teacher of anatomical facts, but, having a thorough knowledge of ancient and modern classic writings, he used them in the lecture-room with great interest and benefit to the student. He was an enthusiastic collector of anatomical specimens, and had probably the best osteological museum in the country, if not in the world.

—— AUGUSTUS VAN CORTLAND, M.D., one of the oldest physicians in Westchester County, N. Y., died at Mount Vernon, on Tuesday, December, 23d, at the age of fifty-eight years. He was a surgeon in the Union Army during the late Civil War.

—— A despatch from Berlin says that DR. GRIMM, the Body Physician of Emperor William, is dead. He was the originator of the sanitary system adopted by the German military authorities.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 23 TO DECEMBER 29, 1884.

MCPARLIN, THOMAS A., *Lieutenant-Colonel and Assistant Medical Purveyor.*—Granted leave of absence for three months, on surgeon's certificate of disability.—*S. O. 301, A. G. O.*, December 24, 1884.

JOHNSON, HENRY, *Captain and Medical Storekeeper.*—Directed, in addition to his present duties, to perform the duties of Assistant Medical Purveyor in New York City.—*S. O. 301, A. G. O.*, December 24, 1884.

WALES, P. G., *First Lieutenant and Assistant Surgeon.*—Relieved from duty in Department of Colorado, and ordered to Department of Arizona.—*S. O. 128, Division of the Pacific*, December 27, 1884.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

ORIGINAL LECTURES.

PSEUDO-HYPERTROPHIC MUSCULAR PARALYSIS.

A Clinical Lecture delivered in Rush Medical College, Chicago.

BY NORMAN BRIDGE, M.D.,

PROFESSOR OF HYGIENE, AND ADJUNCT PROFESSOR OF THE PRINCIPLES AND PRACTICE OF MEDICINE.

GENTLEMEN: The lad who is before you has a curious disease. As he walks in, you observe that he has a waddling gait, and seems to be lame on both sides; he lifts his feet as if they were weighted, and carries them far apart, and as he steps he throws the foot forward slowly and with difficulty, and his step is short. As he sits here before you, he would hardly be supposed to be sick. He looks a little pale from having been much indoors; his face is thin, and his large head and broad forehead give him an appearance of mental strength that does not exist. His peculiar movements as he walks in are the result of weakness; all his muscles are weak, and his movements indicate this fact. He sits easily in his chair, but when he attempts to get up he is unable to do so in the usual manner. He has not strength to rise directly from his seat as one usually does, but he awkwardly turns his body round before rising, faces backward, and by the aid of his hands, resting them first on the seat and then on the back of the chair, he helps himself to rise to a standing posture. In executing the manœuvre he uses all fours, and if he should attempt to rise from the recumbent posture he would be obliged to turn first to the prone position and, after rising to a position on his hands and knees, to help himself up to a standing posture by means of his hands against his knees and thighs. As he reaches the perpendicular, you discover that he first staggers and shakes slightly till he gets the grasp of his equilibrium, when he slowly walks off with the peculiar gait. In going up stairs he is obliged to use all fours, creeping from step to step.

As he stands, you see that his shoulders are thrown far back, and the lumbar region of the spine is deeply arched; the spinal column is in a state of lordosis. This curvature is seen to be even more marked when the clothing is removed. The lordosis is present only when standing—as the patient sits it disappears entirely. On stripping the patient another feature is noticeable, namely, an attenuation of the muscles over portions of the body. Not only is there little adipose tissue, but the muscles seem to be even thinner and less developed than normal. Possibly over the pectoral region and over the area of the latissimus dorsi muscles the flatness is greater than over the general surface, but the difference is not very marked. The calves of the legs are an exception to this general appearance of muscular poverty; they are actually enlarged beyond their normal size. We are told that they were formerly much larger than they are now; so large, indeed, that they were the subject of remark by all who saw them, and that medical advice was sought on account of this unusual appearance.

The boy is ten years old, and, his mother tells us, has never had any acute sickness, except an occasional slight sore throat. He was tardy in learning to creep and to walk, and was always weak in his legs. He early—probably by or before his fifth year—showed the lordosis of the spine, but since his sixth year this symptom has steadily grown worse, and the weakness has also steadily increased. For half his lifetime he has been obliged to rise from his chair and to go up stairs in the way I have described. The calves bulged markedly till within two years—latterly they have become less prominent. Slight exercise causes fatigue, and on becoming chilled he often complains of aching of his thighs and back. He has dyspepsia, and often passes undigested food by the bowels, and his extremities are often discovered to be cold. Otherwise he seems to be in fair general health. He acts and talks in a shy manner, and like a child somewhat younger. He is very quiet, and does not attempt to join his playfellows in any active sport.

This clinical picture is that, almost unmistakably, of one disease. So far as is now known, no other disorder much resembles it. It is pseudo-hypertrophic muscular paralysis, and is so named—or receives its qualifying designation—from the apparent hypertrophy of the muscles, as we see in the calves of this patient.

In this disease the muscles actually waste, while there occurs an increase in the connective tissue and fat about and among them. Some of the muscular fibres undergo degeneration and apparently become connective tissue. The tissues surrounding the muscular fibres undergo hypertrophy, the muscular tissue wastes (from pressure, probably), and the paralysis is the paralysis of weakness. Nearly all the muscles waste, the pectoral and the latissimus dorsi perhaps most, but the hypertrophy is not uniform over the body. The bulging occurs most in the calves, as in this case, but may occur at the seat of the masses of muscle in various parts of the body, giving a false appearance of great muscular development. Some cases, unlike this one, have slight talipes, the heels being raised, from contractures in the muscles connected with the tendo Achillis. The disease invades the muscles of the heart, and causes death from weakness or paralysis of this organ. The invasion of the muscles is general over the body, and so, while it is a muscular atrophy, it differs in this particular from the so-called progressive muscular atrophy. In the latter disease the several muscles are attacked in succession, those of the upper extremity first, and the muscles that are spared remain in their integrity for years after the disease begins. Moreover, in the progressive muscular atrophy there is no pseudo-hypertrophy, and the disease usually occurs in adults.

The pseudo-hypertrophic muscular paralysis begin

in childhood, attacks the muscles of the body generally, slowly and progressively increasing, usually without a halt, till death ensues. This event usually occurs by or before the period of puberty is reached. If the disease ceases its progress for a time, it does not disappear nor much improve, but after a period of quiescence it marches on to a fatal termination. It occurs most often in boys. In a portion of the cases there is a lesion of the spinal cord, probably consisting in an inflammatory change in the gray matter. The anterior cornua and the lateral portions of the gray matter have been found, post mortem, in a condition of disorganization. What relation the changes in the muscles bear to those in the cord nobody knows; which of these lesions precedes the other in point of time is not known, and all calculation as to whether the disease begins in the cord and leads to the changes in the muscles, or *vice versâ*, is unsettled by the fact that in some of the cases careful post-mortem examinations have failed to discover any lesion of the cord of any kind or degree. Possibly more searching methods may in the future demonstrate that lesions of the cord are invariable. The clinical fact of significance to us is that in this affection the lesion of the muscles always exists; of that we are certain. That there is always lesion of the cord, gross or minute, is perhaps true.

The mind is usually unaffected except that it is weak, in some cases very weak. A few of the children late in the disease pass into a condition of idiocy. This is an event that should not surprise us when we consider the spinal lesions which sometimes exist and when we reflect that such changes may easily extend to the brain.

There has been some speculation as to the mechanism of the lordosis. It has been attributed to weakness of the extensor muscles of the spine, but on this theory the phenomenon ought not to disappear in the sitting posture. A better explanation is this: that as the patient stands the pelvis is unnaturally flexed upon the thighs owing to weakness of the extensor muscles that counteract this tendency; it is tipped or inclined forwards and the deep curvature of the spine is simply in compensation for this and to enable the patient to maintain the erect posture and his equilibrium.

There ought to be little danger of confusing this disease with any other. A few symptoms are always present, and, appearing together, they are diagnostic. Yet the disease has been mistaken for some affection of the spinal bones, for disease of the hip-joints and partial paralysis of the lower extremities. In a child with lordosis of the spine, a waddling, unsteady gait with the feet far apart, and the peculiar manœuvre on rising from the sitting and recumbent postures, if there is bulging of the calves with or without the same feature in other parts of the body, you may say surely that it is a case of this disease. These few elements are always present in greater or less degree: the youth of the patient; the lordosis; the characteristic gait; the peculiar manner of rising to the standing position; bulging over of certain muscles and the general weakness. Not only are all these present in this disease, but they are not present together in any other affection whatsoever.

The prognosis is grave indeed, and must so remain till more is known of the etiology and proper treatment of the disease. So far the patients all die before they reach adult life. Death may occur from exhaustion—which means, chiefly, heart exhaustion—and it may result from some intercurrent disease.

This peculiar affection is to a certain, probably we ought to say to a slight, extent hereditary. It would be more properly called a diathetic disorder that may be peculiar to a family. Certain families have shown a predisposition to it and have suffered its occurrence in several successive generations.

The treatment is theoretical and experimental. No treatment has had any particular influence over the disease. Various tonics, phosphorus and arsenic, and electricity, have been tried, with slight or no effect on the progress of the malady. As the weakness rapidly increases when the patient ceases to exercise, it is desirable to keep up some vigor of the muscles as long as possible by exercise and manipulation. In the present case some elixir of calisaya with nux vomica has been given during the past week for the dyspepsia, with the effect of partially removing it. But we cannot look for any improvement in the condition of the muscles and connective tissue from this treatment. The improved digestion may enable the patient to maintain his strength a little longer and postpone a little the day of dissolution, but I have no faith that anything more will be accomplished by it. To facilitate the general nutrition daily inunctions of oil over the entire body, with rubbing, have been ordered.[1]

ORIGINAL ARTICLES.

THE GERMICIDE POWER OF POTASSIUM PERMANGANATE.

By GEORGE M. STERNBERG, M.D.,
Major and Surgeon, U. S. Army.

In the very instructive paper by Prof. Bartholow on "Permanganate of Potassium: its Action and Uses," published in The Medical News of November 22, 1884, the following reference is made to my experiments relating to the germicide action of this agent:

"Most of the experiments made have been with microbes contained in culture-fluids; for example, the very able and elaborate research made by Dr. Sternberg.[2] Under these circumstances, the results are better than can be achieved from the use of the same antiseptics in disease, *cæteris paribus*."

This statement is undoubtedly correct, and is especially true as regards an agent like potassium permanganate, which is very quickly decomposed in the presence of organic matter. It is for this reason that in the experimental research referred to by

[1] This case was reëxamined four months after its presentation at the clinic. It was found that the boy had added perceptibly to his stature; that he had been in better vigor than for several years; that no dyspepsia had occurred and that he was able to move about quite as well, possibly slightly better, than at his former visit. There had developed slight talipes varus and the bulging of the calves had decreased. The treatment had been continuously kept up, both as to the medicine and the inunctions and manipulations. The material used for the inunctions was, most of the time, olive oil, and it had been applied each day once.

[2] Experiments to Determine the Germicide Value of Therapeutic Agents. Amer. Journ. Med. Sciences, April, 1883.

Prof. Bartholow, which had special reference to therapeutic possibilities, the writer dropped the permanganate from the list of substances to be studied from this point of view, after having determined that it had very decided germicide power. It destroyed the vitality of the micrococcus of pus in the proportion of 1 to 833.

This germicide power cannot, however, be made available for the destruction of germs in the blood or tissues for the reason that the permanganate is itself quickly decomposed by contact with organic matter. This point will be referred to later, and some recent experiments will be reported which show that, under the conditions mentioned in my paper above referred to, this agent does destroy germs in the proportion given. Prof. Bartholow continues:

"Sternberg assigns to bichloride of mercury (mercuric chloride) the first place as an antiseptic; yet he puts permanganate of potassium second."

There is a mistake here which seems to result from the use, by Prof. Bartholow, of the terms germicide and antiseptic as synonymous. Mercuric chloride does appear at the head of the list both of germicides (Table No. III.) and of antiseptics (Table No. IV.); but potassium permanganate only appears in Tables Nos. I. and II., which relate to the *germicide* power of the agents named, as proved by their power to destroy the vitality of a single test organism—a micrococcus.

For the reason already stated, the permanganate was dropped, after this preliminary trial, from the list of *therapeutic* agents which the writer proposed to test with reference to their *germicide* power. As I consider the distinction between germicides and antiseptics to be a very important one, I take the liberty of introducing here the definition which I have given in the chapter on "Germicides and Antiseptics" in my work on *Bacteria*.

"By a *germicide* agent we mean one which has the power to destroy the vitality of the various species of bacteria known to us, including those disease-germs which have been demonstrated, such as the anthrax bacillus, the bacterium of symptomatic anthrax, the micrococcus of fowl cholera, that of septicæmia in the rabbit, etc. *Germicides* are also *antiseptics*, as the bacteria of putrefaction are killed by them as well as those mentioned. They may also arrest putrefactive decomposition in quantities less than are required to destroy completely putrefactive organisms. But an antiseptic is not necessarily a germicide, for experiment proves that certain substances arrest putrefaction which have not the power to kill the bacteria to which this is due. This they do by arresting the vital activity—multiplication—of the germs of putrefaction, or by so changing the nutritive pabulum required for the development of these germs that they are unable to appropriate it to their use."[1]

As examples of antiseptics which are not germicides—except in the strongest solutions and after very long exposure—we may mention chloroform and alcohol, which inhibit, so to speak, the development of germs; and the metallic salts, such as sulphate of iron, sulphate of zinc, etc., which prevent the multiplication of germs by precipitating the albuminous material in fluid media which would otherwise furnish abundant pabulum for the development of putrefactive bacteria.

Having thus made clear the distinction which the progress of our knowledge in this direction has made it necessary to establish, with reference to the agents which were formerly all classed together as "antiseptics"—a distinction which alone justifies the use of the term *germicide*—I would remark that permanganate of potassium occupies the second place in my Table No. II., not because it ranks next to mercuric chloride among all known germicide agents, but because it has this relative position in the limited list which I selected, for special reasons, for the experimental research, the results of which are reported in the paper referred to.

I may be permitted to remark, *en passant*, that experiments of this nature take a great amount of time, and that the only reason why a larger list of chemical agents was not included in the above-mentioned research was that the writer had no assistance and was obliged to restrict his experimental work within the limits imposed by his own available time and pecuniary resources. Fortunately, circumstances are at present more favorable for the prosecution of work of this character, and I am now engaged in an extended research upon the "comparative value of disinfectants," which I have undertaken in conformity with the wishes of the American Public Health Association, and with the substantial assistance of several of the most active State Boards of Health. This pecuniary aid has enabled the committee, of which I am Chairman, to secure the services of two very competent assistants, who are now actively engaged in the work under my direction and with all of the personal assistance which other duties enable me to render. It has been decided by the committee that the results of our investigations shall be published from time to time in some leading medical or sanitary periodical, in advance of our complete report to the Public Health Association, at its next annual meeting, in order that they may be utilized by health officials and by the public in case of an epidemic of cholera next summer.

I proceed to quote from Prof. Bartholow's article, which, with due respect, I have taken as a text in the present communication, with a view to showing how many elements enter into the equation when the statement is made that a given agent is a germicide in a given proportion. Dr. Bartholow says:

"Whilst bichloride is effective in the proportion of 1 part to 20,000 of fluid, the permanganate of potassium acts to the same degree in the proportion of 1 part to 833 of solution."

Now, it must be remembered that these results relate to a single test-organism, and that the time of exposure adopted was two hours. They cannot, therefore, be compared directly with other experiments made by a different method, upon different organisms, and with a different time of exposure. All of the results reported by different authors, even by those who have been the most careful and exact in the application of the tests adopted, must be looked upon as approxi-

[1] Op. cit., p. 210.

mate, and not as exactly representing the germicide power of the agent named. Thus in my experiments with permanganate of potash, I commenced with a four per cent. solution, and, finding this effectual, sought to ascertain the limit of germicide power by diluting my standard solution after each experiment with an equal quantity of distilled water. This gave me the following series of experiments, in which no development of the test-organism occurred in a sterile culture-solution inoculated with the germs—micrococci—after two hours' exposure to the germicide agent, viz.: 4 per cent., 2 per cent., 1 per cent., 0.5 per cent., 0.25 per cent., 0.12 per cent. (last experiment in duplicate). Upon again diluting the standard solution one-half (making 0.06 per cent.), it failed to destroy the vitality of the micrococci, which multiplied freely in a sterile culture-solution in the presence of this amount. Here, then, we have the line between success and failure drawn between the limits 0.12 per cent. = 1 : 833, and 0.06 per cent. = 1 : 1666. To establish the exact limits for the germ in question, it would be necessary to try numerous experiments between these limits, and not only to exercise the greatest care in weighing or measuring the standard solution, but to operate each time upon the same number of germs contained in a uniform quantity of culture-fluid of uniform composition. These conditions might possibly be fulfilled, but from a practical point of view it is hardly necessary to insist upon their being fulfilled, inasmuch as the limits established are sufficiently accurate to serve as a guide for the use of this agent in disinfection. But in applying the experimental data here given, it must be remembered that the permanganate itself is destroyed by contact with organic matter, and that the destruction of micrococci in a drop of culture-fluid is a very different thing from the destruction of the same microörganisms in a large amount of organic material, as, for example, in the blood of an animal, or in liquid feces, by which the permanganate in dilute solution would be almost instantly decomposed.

In the writer's experiments, made in Baltimore in 1881,[1] it was found that 1 part in 50 was required to destroy the septic micrococcus in the blood of a rabbit just dead from induced septicæmia, the test of disinfection being inoculation of healthy rabbits with the disinfected material. According to Arloing, Connevin, and Thomas, a five per cent. solution destroys the fresh virus of symptomatic anthrax, but has no effect upon the dried virus. These statements are not at all in conflict with the results reported in my experiments heretofore referred to, and these results are substantiated by the following recent experiments made by the same method:

Nov. 26, 1884, a pure culture of the micrococcus of pus was subjected to the action of potassium permanganate for two hours in the proportion of 1 part to 500, and in the proportion of 1 part to 1000. Four culture-tubes containing a sterilized solution of beef-peptone were inoculated with the micrococci thus exposed (it is my practice to make every experiment in duplicate), and were placed in a culture-oven maintained at 38° C. (100.4° F.) for forty-eight hours. No development occurred in either of the tubes.

On the 29th of November, a similar experiment was made with a culture-solution containing both micrococci and bacilli. In this experiment there was no development of the micrococci, but the bacilli developed abundantly after exposure to the 1 to 1000 solution. No development of bacilli (*B. subtilis*) occurred, however, after exposure to 1 part in 250. In these experiments the permanganate, although in dilute solution, was not neutralized by the small amount of organic material contained in the drop of culture-fluid exposed to the action of the germicide agent. In the following experiments the conditions were varied, and a larger proportion of the permanganate failed to exert any germicide power.

Nov. 24th, equal parts of a 0.4 per cent solution (1 : 250) of potassium permanganate and of "broken-down" beef-tea were mixed in a germ-proof receptacle, and allowed to stand for two hours. Two culture-tubes were then inoculated with a minute drop of the mixture, and were placed in the oven. At the end of twenty-four hours, an abundant development of putrefactive bacteria had taken place. In this experiment, then, we have a failure in the proportion of 1 : 500, but the experiment does not in the least invalidate those previously reported. The truth is, that in making the above mixture the permanganate is almost instantly decomposed by the excess of organic matter, while in the experiments in which a single drop of culture-fluid containing micrococci was introduced into a more dilute solution, there was still an excess of the permanganate, as shown by the color of the solution at the end of two hours. Having determined the germicide power of the permanganate for micrococci, at least for one species of *Micrococcus*, I desired to know whether the oxidizing power of this reagent, when present in excess, would destroy the spores of anthrax, which are recognized as furnishing one of the most difficult tests of germicide power. The following experiments have been recently made:

Nov. 24th, a drop of culture-fluid, containing an abundance of anthrax spores, a pure culture, was added to a considerable quantity of a 4 per cent. (1 : 250) solution of potassium permanganate. After two hours, two culture-tubes were inoculated with a minute quantity of this material. These tubes were placed in the culture-oven, and the following morning contained an abundance of anthrax bacilli.

Nov. 27th, the above experiment was repeated, except that the time of exposure was extended to four hours. Again there was an abundant development of anthrax bacilli in the culture-tubes, showing that the spores had resisted; but in one tube the development was delayed, and it was only on the morning of the second day that flocculi of *bacillus anthracis* commenced to appear.

Dec. 2d, the experiment was repeated, with the exception that the time of exposure was extended to four days. The bacillus now failed entirely to develop in the culture-tubes, showing that the spores had been killed by this long exposure.

[1] Bulletin National Board of Health, July 23, 1881; also, Studies from Biological Laboratory of Johns Hopkins University. Vol. ii., No. 2.

It is probable that, in experiments in which the permanganate is present in excess, the amount present is of less importance than the time of exposure, and that a much stronger solution would fail to destroy anthrax spores in a short time. The wide difference in the potency of this agent and of mercuric chloride is shown by the fact that 1 : 250 failed to destroy anthrax spores in four hours; while, according to Koch, 1 : 10,000[1] of corrosive sublimate destroys these spores in ten minutes.

I expect before long to make a special report upon mercuric chloride as a germicide, and in this paper will endeavor to give a summary of the experimental data at present on record, and a detailed account of my own recent experiments with this agent.

Continuing to quote from Bartholow, we find the following:

"We must acknowledge a certain sense of scepticism in examining these experiments of Dr. Sternberg, as able and well-considered as they unquestionably are. We find it difficult to understand why liquor zinci chloridi has no germicide action, whilst a 2 per cent. solution of the same is effective in the proportion of 1 part to 50."

Dr. Bartholow's scepticism is well founded from his point of view, but it results from a misapprehension. I do not say that liquor zinci chloridi has no germicide action, but I record its failure to destroy the micrococcus used as a test-organism in the following experiments: Commencing at 1 per cent.—the time of exposure being, as in all of these experiments, two hours—and meeting with a failure, the following experiments were made, 2 per cent., 4 per cent., 8 per cent. Meeting with a failure in every case, I proceeded to test the pure salt—zinc chloride. This failed in the proportion of 0.5 per cent. and of 1 per cent., but was successful in the proportion of 2 per cent. (Experiment in duplicate, see Table No. I.) In my Table No. II., this result is stated as follows:

"Zinc chloride (2 per cent.) 1 part in 50."

The misapprehension has arisen from the fact that Prof. Bartholow has taken this to mean that 1 part in 50 of a 2 per cent. solution is efficient, whereas it means that 1 part in 50 of the pure salt is efficient, and the 2 per cent. in parenthesis is simply introduced from the previous table as the equivalent of 1 part in 50.

According to *The National Dispensatory*, the liquor zinci chloridi should contain about 50 per cent. of the pure salt. If the specimen tested was of this strength, it should have been efficient in the proportion of 4 per cent., or 1 : 25; but it failed in two experiments in this proportion, and in one in the proportion of 8 per cent. The biological test is sufficiently accurate to make it appear probable that this particular specimen did not come up to the standard as laid down in the *Dispensatory*.

[1] In the chapter on Germicides and Antiseptics in my recent work (*Bacteria*), the figures are erroneously given as 1 : 1000. This mistake resulted from the fact that I had not access to the original report of Dr. Koch, and was obliged to obtain my figures from abstracts in medical journals at hand. Unfortunately, the figures were incorrectly given in the journal from which I

Another sample by the same maker, purchased in a drug store in this city, has recently been tested, at my request, by Dr. Duggan (M.D., Ph.D., and late Fellow in Chemistry in Johns Hopkins University), whose valuable assistance I now have in the prosecution of these experiments. Dr. Duggan reports that this sample failed to destroy the bacteria in broken-down beef-tea (2 hours' exposure) in the proportion of 5 per cent. and of 7 per cent., but was effectual in 10 per cent. It would appear, therefore, that my last experiment (8 per cent. failed) was just within the limits of the proportion which would have been successful if the samples tested were identical in composition.

Dr. Duggan's experiments were made in duplicate, and by the method described in detail in my paper referred to by Prof. Bartholow.

I now pass to the last clause of Prof. Bartholow's reference to my experiments. He says:

"As the experiments of Miquel have been more recently performed, and the conditions insisted on by Jalan de la Croix more perfectly observed, we may rather accept his conclusions in regard to the real value of permanganate of potassium as a germicide."

It is, perhaps, open to question whether the experiments of Miquel are more recent than my own. He says, in his work published in 1883:

"Les récherches longues et fastidieuses que j 'ai entreprises depuis deux ans sur cette matière me paraissent assez avancées pour qu'ou puisse déja en retirer quelques indications utiles" (p. 291).

My own experiments were published in April, 1883, and there is no evidence that those of Miquel have priority as to date. But this is a matter of comparatively small importance. The question is as to the comparative value of the two series of experiments. As regards the permanganate of potassium, they cannot be compared at all, as my experiments relate solely to the *germicide* power of this agent upon a single test-organism; while those of Miquel relate to the power of this and other agents to prevent the development of the bacteria of putrefaction in a given quantity of beef-tea (1 litre). Miquel's experiments establish, by a very satisfactory method, the *antiseptic* power of the agents studied by him, but give no definite evidence as to the *germicide* power of these agents.

In the case of permanganate of potassium, the immediate effect of adding this agent to a litre of beef-tea would be, if it were added in excess, to destroy by oxidation all of the organic material in the fluid, and to decompose a corresponding amount of the salt. The excess of the salt would then have time to act upon any spores of bacilli and other germs present; but even if not destroyed, these would not develop, for the reason that all of the pabulum suitable for their development would have been quickly destroyed by this powerful oxidizing agent.

In my experiments to determine the minimum quantity of various reagents which would prevent the development of bacterial organisms—that is, to determine the *antiseptic* value of the reagents named —I purposely excluded the permanganate of potas-

sium, for the reason above indicated. But the experiments with other agents were made by a method quite as reliable as that of Miquel, and, indeed, by one which does not differ materially from it, except as regards the quantity of fluid employed. In these experiments, I added a given quantity of the agent to be tested to a culture-fluid, introduced this culture-fluid into a number of the little flasks which I so constantly use and have repeatedly described, sterilized the fluid in the flasks by long boiling, and then tested the power of the various test-organisms to develop in the flasks in the presence of a given quantity of the reagent under trial. By multiplying these experiments, and adding more or less of the reagent, according as development occurred, or otherwise, I determined the minimum quantity of each reagent which would restrict development. I found, for example, that all of the test-organisms multiplied freely in the presence of 0.1 per cent. (1 : 1000) of carbolic acid, and that none of these organisms multiplied in the presence of 0.2 per cent. (1 : 500).

In regard to the method which I have employed and continue to employ, I would say, finally, that it fully meets the most rigid exactions of science; that it has the approval of experts in chemical and in biological investigations at the Johns Hopkins University who are familiar with it; and that I shall be very happy to demonstrate its special advantages to Prof. Bartholow, or to any physician or sanitarian who may desire to satisfy himself of the reliability of the results which I have reported, or may hereafter publish, if he will do me the favor to call upon me at the laboratory where I am now engaged in extended experimental investigations in this direction.

I have considered it necessary to be thus explicit, because it is evident that the misapprehension which has led so distinguished a physician and teacher as Dr. Bartholow to express a certain scepticism in regard to my experiments relating to permanganate of potassium, may also influence others for whose benefit this voluntary work has been done, and thus neutralize the value of my efforts for the advancement of exact knowledge in this direction, and take away the only reward which an investigator can hope for, viz., the appreciation and confidence of his professional confrères.

The experiments of De la Croix, like those of Miquel, have reference especially to the antiseptic power of the agents tested by him. He makes the statement, however, that one part of potassium permanganate in thirty-five, kills the bacteria of broken-down beef-tea. This statement is, no doubt, true, under the conditions of his experiment; but, as I have shown, the result depends upon the time of exposure and the amount of organic matter present, quite as much as upon the proportionate amount of permanganate with reference to the quantity of fluid operated upon. If we add one gramme of permanganate to a litre of broken-down beef-stock, it is quickly decomposed, and no germicide effect is produced; but if we add one drop of putrid beef-tea to a litre of distilled water containing one gramme of permanganate, the organic matter, and the germs as well, contained in this drop of fluid are quickly destroyed by oxidation.

Several English investigators—Notter,[1] Calvert,[2] and Tripe[3]—have attempted to determine the value of potassium permanganate as a "disinfectant;" but the methods employed have not been such as could give satisfactory and definite results, although these earlier experiments demonstrated the value of this agent as an antiseptic and deodorizer.

Other English investigators—Baxter,[4] Braidwood, and Vacher[5]—have adopted a different test, and their results are interesting and valuable.

These gentlemen operated upon vaccine lymph, and the test of disinfection was the failure of this lymph to produce characteristic vesicles upon the arms of children not previously vaccinated. Comparative experiments were made in each case with lymph not subjected to the action of the disinfectant.

In Baxter's experiments, one part in 200 was successful in destroying the specific virulence of vaccine lymph; and in those of Braidwood and Vacher, a like result was obtained by adding two drops of a solution of 1 : 120 to "a tube of lymph."

From what has been said, it is evident that, while potassium permanganate has decided germicide and antiseptic power, it is not generally applicable for purposes of disinfection, because of the readiness with which it is decomposed by organic matter. It is, however, a prompt and valuable deodorizer.

Finally, I have a practical suggestion to make in regard to the use of this agent. We have ample experimental evidence showing the germicide potency of mercuric chloride; but in domestic sanitation there will always be some apprehension of accident on account of the poisonous character of this agent, and the absence of all color or odor in a solution containing it.

Now, the permanganate of potassium has an intense color in dilute solutions, and there would be no danger that a liquid containing it might be mistaken for a potable fluid. No chemical reaction occurs when corrosive sublimate and the permanganate are mixed in the same solution, and I propose the following as a standard "disinfectant" for domestic and general use—for the special purposes for which such a solution would be applicable, viz., the disinfection of sputum (in diphtheria, tuberculosis, etc.), and of liquid feces (in cholera, typhoid fever, etc.):

Bichloride of mercury and permanganate of potassium, of each two grammes. Distilled (or boiled and filtered) water one litre.

This gives exactly one part of each of the salts to 500 of water. A solution of two drachms of each of the salts to a gallon of water would come near enough to this strength for practical purposes.

Experiments recently made indicate that this would be an efficient disinfectant for liquid feces, etc., if used in an amount equal to the material to be disinfected. (Full details of these experiments will be published hereafter.) The permanganate in this standard solution, in addition to the protection which its color would afford, has the advantage of acting as a prompt deodorizer, while the bichloride has no deodorizing power.

It must be remembered in practice that the germicide power of such a compound is not instantaneous, and it will be necessary to leave the material to be disinfected for an hour or more in a vessel with the disinfectant before it can be safely thrown into a privy-vault, or other receptacle where fresh pabulum for pathogenic bacteria may be present.

REMARKS UPON CHRONIC CONTRACTED KIDNEY WITH NORMAL URINE,

INCLUDING ACUTE GOUTY DEMENTIA WITH A PERFORATING RECTO-VAGINAL ULCER, AND DEATH FROM SUDDEN PULMONIC ŒDEMA.[1]

BY H. C. WOOD, M.D.,

CLINICAL PROFESSOR OF NERVOUS DISEASES IN THE UNIVERSITY OF PENNSYLVANIA, AND NEUROLOGIST TO THE PHILADELPHIA HOSPITAL.

MRS. L., an intelligent lady, about forty years of age, the mother of five children, of gouty ancestry. At regular intervals of four years she was accustomed to have very violent acute attacks of gout or rheumatism associated with great systemic disturbance and depression of spirits. As the last gouty sickness was in the early spring of 1880, she was in the spring of the present year in great fear of another attack, and an attempt was made under the direction of her medical adviser, Dr. Tomlison, to ward off such sickness by careful diet and free horseback exercise. For the early notes of her case I am indebted to Dr. Tomlison. An exposure to cold during the night of April 20 was followed by severe coryza, vague pains, and great hebetude with a very pronounced desire to sleep. Even when moving about she seemed unable to keep her eyes open. Under treatment she improved temporarily. Dr. Tomlison writes concerning this period, "I could discover nothing wrong with the urine, which she passed in usual quantity. A week later she began to have difficulty in expressing herself; she would use irrelevant words and then correct herself; her gait also grew uncertain, and in walking she would pitch forward as if she were going to fall. April 28, Mrs. L.'s mother died; Mrs. L. was greatly shocked, and rapidly became worse; she was greatly depressed, lachrymose, hysterical, had hallucinations, and ceased to recognize those around her. She lost her appetite, and became constipated. The uncertainty of movement now affected the arms, and there was great failure of memory. Her symptoms continually deepened, the speech became more and more incoherent, until it was a confused, senseless jargon. She now refused food, and finally staid in bed in a state of perpetual stupor. The tongue was heavily coated, the breath very offensive. There was no elevation of temperature, or pains, or local soreness."

I first saw her May 8; I found her in bed in a sort of stupor, out of which she was with difficulty wakened. Getting her partially aroused, I ordered the nurse to put on a wrapper; then commanding and leading the patient, succeeded in getting her to the head of the stairs, then down stairs. It was necessary to hold her very forcibly, as every few minutes her knees would seem to give way and she would "flop" to the floor. All this time she said nothing other than incoherent protestations. When she finally was in the parlor, I upbraided her loudly and severely for her dishabille and general appearance. On asking her if she was not ashamed of herself, she said she was, and that she had better go upstairs and change her clothes. On my acquiescing, she stood up, and taking the hand of her nurse walked upstairs, dressed herself with assistance, and came down, recognizing people, but saying very little. I left her eating her breakfast. Her urine was examined at this time; it was loaded with uric acid and urates, although she had been eating very little, had a specific gravity of 1024, and contained no tube-casts, and not the faintest trace of albumen.

She came to the city May 11. She was now completely demented, knowing no one and not recognizing in any way her surroundings. The pupils were contracted and immobile. She ate no food except milk, which was forcibly given her at regular intervals. Much of the time she lay in a stupor in bed; then she would have spells of wandering restlessness; again distinct maniacal outbreaks accompanied by violence and indecent speech, or sometimes attacks of muttering delirium. The tongue was brown, dry, coated to the last degree. The teeth were loaded with sordes; the breath horribly offensive; the bowels were obstinately constipated. She was treated with purgatives, quinine, chloral, and morphine when excited.

During these days there was general tenderness, so that whenever she was taken hold of roughly she would scream out, even rousing from a stupor. There was also on movement distinct pain, not located in the joints, but seemingly in the muscles. There were very bad hemorrhoids, and as times the patient lay stupid but moaning, with knees drawn up as though there was abdominal pain. The pulse was quick, never much under a hundred, small and feeble rather than strong. Her mental condition grew worse, she took no note of anything, had to be catheterized, etc.

By May 16, the general tenderness had become very pronounced; the pupils were dilated and movable; the intelligence somewhat improved, in that she began to take notice. Salicylates and digitalis were at this time being used freely. On 17th, severe diarrhœa with involuntary passages set in; also the pulse altered suddenly its character, becoming excessively irregular, from 110 to 150 per minute, with beats of all sizes and rates, and many complete intermissions. General tenderness very marked. Auscultation of the heart showed the first sound very weak

[1] Read before the College of Physicians of Philadelphia, Nov. 5, 1884.

over the right base; at the left apex the first sound was very weak, the second decidedly accentuated. Over the middle cardiac region the sounds were singularly confused, with a peculiar watery and occasionally grating sound, "believed to be cardiac friction, but no clear, positive, to-and-fro friction râle." A blister was applied over the head and one over the heart.

May 18, menstruation had been established; the pulse had become perfectly regular, 100, and the peculiar middle cardiac sound less distinct. Her mental condition so far improved that she indicated when she desired to pass water, but she could not give a coherent answer to the simplest question.

On the 20th, she, when roused, answered simple questions with some rationality. Severe diarrhœa again manifested itself with involuntary passages and lasted many days, indeed, off and on, almost to the end; remedies simply kept it in check. There were no maniacal outbreaks, and a slow but progressive improvement in her mental condition began very distinctly directly after the violent diarrhœa of the 20th. The first change was in the recognition of her husband; then, when she had a desire to stool, she would insist on getting out of bed to the commode, although she never said why she got up. Then she resisted food and medicine, clearly because she had a will not to have them. On the morning of the 20th she took food herself, knew where she was, and wondered greatly as to the way in which she had got there, having no memory of past events.

June 23, it was first noticed that something was wrong with the vaginal discharge, but a vaginal examination failed to detect any abnormality. On the morning of June 25 feces were plainly passed per vaginam, and there was discovered a perforation of the recto-vaginal wall very low down, sufficiently large to admit easily the whole forefinger into the rectum. The edges were soft and not well defined. There was no hemorrhage, local swelling, or pain during the formation of this opening, and it was not distinctly sore.

The mental condition of Mrs. L. continued to improve until about the first of June. At the same time her tongue cleaned and her breath became sweet. June 1, she was entirely rational, recognized her surroundings and friends, servants, etc., in their proper relations. She spoke very sensibly about her own illness. The memory was very much improved, but by no means normal, and there was an absolute lack of power of mental exertion; but the only thing a casual observer would have noted as peculiar was the character of her voice, which remained very unnatural.

The first indication of a relapse occurred about the first of June, in a renewed coating of the tongue; then she began to talk irrationally at night, and her memory rapidly to fail. Then a tendency to drop or elide words from her sentences came on and was very pronounced. Her talk in the night began to be irrational and incoherent. At times she was quiet during the day, at other times very restless. At night she was very wakeful and restless, getting out of bed, wandering about rooms, etc. Much of the time she had an almost uncontrollable desire to pick at her nose and genitals; some days she refused food, others took it. The pulse ranged from 100 to 120, and her physical strength distinctly increased.

From this time onward her mental state deteriorated rather than ameliorated. She lost power of knowing those about her, although she still recognized her husband; the memory was entirely lost; in a word, she was in a condition of almost complete dementia. July 18th, the breathing became suddenly accelerated, and some fine subcrepitant râles were heard posteriorly; on the morning of the 18th, her breathing grew much worse; the whole upper lobe of right lung was full of very fine crepitation, the left lung also containing râles. This continued for two days with some slight dulness of percussion on left apex, and then gradually subsided. Some days after this she had an equally sudden attack of œdema of the feet. June 24, she was taken about 11 P.M. with violent dyspnœa accompanied by fine crepitation anteriorly and superiorly in both lungs, and almost complete absence of breath sounds over the posterior lobes. The dyspnœa steadily increased and she died asphyxiated after twenty-four hours of struggle.

Autopsy.—Kidneys large, plainly in the early stage of chronic interstitial nephritis. Heart somewhat hypertrophied; valves normal. Much excess of fluid in pericardium, but no exuded lymph. Lungs highly œdematous; considerable peritoneal as well as pleural serous effusion.

Brain: Basilar arteries; walls very much thickened, sufficiently so to interfere distinctly with lumen; smaller arteries also showing signs of similar endarteritis; the upper and to some extent the basal submembranous spaces everywhere distended with exuded fluid; fine vessels of the membrane somewhat congested; a very little lymph in some spots in the membranes. Brain substance very anæmic; the convolutions appeared shrunken; consistence normal, no spots of softening or macroscopic changes to be detected; microscopical examination of the convolutions failed to demonstrate anything abnormal, although the cells were perhaps more granular than normal.

There are certain points about this very remarkable case to which it may be worth while to direct the attention. The cause of the dementia cannot positively be asserted; but I am very strongly inclined to think that it was, at least in part, due to gouty irritation.

It seems to me well established that gout is capable of causing almost every form of insanity; indeed, insanity is only an increase of the mental conditions frequently seen in lithæmia. Carrol, in 1859, said, "Gouty mania is occasionally seen," and in 1875, Dr P. Berthier (*Des Nevroses Diathesiques*, Paris) published a collection of 46 cases of nervous disease attributable to gout: 1, hallucinations; 1, migraine; 4, tetanus; 3, chorea; 1, hypochondria; 7, epilepsy; 1, paralysis, and 26 of mental affection, including in these dementia, melancholia with stupor, mania. Although in some of these cases the evidence is not at all positive that gout was the *materies morbi*, yet in others the relation seems to have been clearly made out.

In his paper before the International Congress of London (vol. iii. 640), Dr. Raynor supported the following conclusions:

1. Protracted gouty toxæmia when not very intense, usually results in sensory hallucinations or melancholia.

2. Sudden and intense toxæmia results in mania or epilepsy.

3. Intense and protracted toxæmia usually results in general paralysis.

4. If there be a tendency to vascular degeneration from plumbism, alcoholism, etc., varying degrees of dementia are produced

In the discussion which followed the reading of Dr. Raynor's paper, Drs. Savage and Crichton Browne, of London, both expressed the belief that gout does cause insanity, the latter, however, qualifying by the statement—only where there is hereditary predisposition to insanity.

Further proof of the connection between gout and insanity may be found in the Paris Thèsis of M. Belliard (1882, No. 269), in which are detailed various cases.

The facts that, in Mrs. L., the attack was at the time when an explosion of gout was to be expected; that in all her previous attacks mental depression was a distinct feature; that her urine was loaded with lithates, although she was taking very little food; and that there was widespread exquisite tenderness and soreness to movement, with febrile reaction, appear to establish a gouty etiology. The contraction of the lumen of the basilar arteries was seemingly sufficient to check the freedom of blood-supply to the brain. Brain anæmia certainly existed, as was proven by the autopsy, and no doubt it aided in causing mental weakness.

It is certainly worthy of remark, as confirmatory of the generalizations made by Dr. Raynor, that the type of mental disturbance exactly corresponded with his conclusions. There was a pronounced tendency to vascular degenerations, and the mental disturbance partook of the nature of dementia.

Passing from the discussion of the etiology of the case, we note the rapid formation of a recto-vaginal circular ulcer as most extraordinary; its occurrence was entirely spontaneous. It seems to resemble in its nervous pathology the rapid eschars which sometimes form upon the buttock and extremities in severe myelitis, or, perhaps, even more closely the so-called perforating ulcer of the foot.

The temperature sheet of this patient was remarkable, owing to the differences between the two axillæ; although, as the autopsy showed, there was no focal brain lesion to account for such difference.

Irregularities of local temperature are well known to occur in diseases of the brain, and the temperature in the two axillæ in the present case was first tested for diagnostic purposes. The result shows that we may have such irregularities of temperature when there is no local lesion. In a case now under my care at the Philadelphia Hospital, believed to be suffering from an acute myelitis, the temperature for many days varied in the two axillæ from 0.2° F. to 1.5° F. To my mind, it is evident that we need careful bilateral studies of temperatures in various diseases.

The point to which I want to direct especial attention, however, is that the urine was examined at various times by Dr. Tomlison without his finding any evidence of contracted kidney, although such lesion existed. My first glance at the patient made me think that she had chronic Bright's disease, but a very careful examination of the chemical reactions, the specific gravity, and the microscopic deposits of the urine so entirely failed to justify any suspicion that I was entirely misled in this feature of the case. I should here state that my own examinations of the renal secretion were so entirely in accord with the statement of Dr. Tomlison, that they were not, as they ought to have been, repeated upon various specimens of the urine. As already stated, the aspect of Mrs. L. suggested the existence of chronically contracted kidney, but there was no increased arterial tension; the heart's action, whilst she was under my care, being uniformly feeble. It is many years since I ceased putting confidence in the absence of albumen as being of much value in disproving the existence of contracted kidney, but I have hitherto believed that reliance could be placed upon the specific gravity of the urine. The importance of examining the specific gravity of the urine cannot be overestimated; and the import of a persistent specific gravity of 1010 or under can scarcely be mistaken; but in addition to the case just detailed, the following is of great interest as indicating that normal urine may accompany a fatally diseased kidney.

Mrs. —, aged 58, the mother of two healthy children, consulted me in the month of April, 1883, on account of certain spells which afflicted her. The history she and her daughter gave was in brief as follows: The attack first began in 1876, about the time she ceased menstruating, and had continued ever since; they always came on when the stomach was empty, and were sure to happen if at any time during the day she was more than three hours without food; also if she does not get breakfast upon rising, she is sure to have a seizure; excessive fatigue increases the tendency to attacks. The spell commences with extreme pallor of face, and dark rings under her eyes: if walking her gait becomes very slow, if talking her speech slackens and then ceases; she looks around in a dazed, bewildered manner, but does not fall, and is not convulsed at all; she does not become completely unconscious, but does not know where she is or what is going on about her; if a mouthful or two of food be forced down her, she arouses immediately, but has no memory of what has occurred during the spell. A careful examination of Mrs. — resulted in complete negations, so far as organic disease was concerned. The urine was normal; there was no failure of mental power, choked disk, palsy, headache, or other local symptom discoverable, and I finally settled down to the diagnosis of gastric vertigo. Under appropriate treatment, the patient improved, and I saw her at my office for the last time July 4, 1883.

In April, 1884, I was hastily summoned to her bedside, and found her comatose, with a history of distinct convulsions, which were said to have been diagnosticated as hysterical by a neighboring practitioner, who I was also told, after examination of the

urine, had stated positively there was no disease of the kidneys. On post-mortem examination, the brain was found normal, but the kidneys presented the gross appearances of advanced contracted kidney; and careful microscopical examination by Dr. G. A. Piersoll proved that the condition of the organ was as it appeared.

A second case bearing upon the matter in hand, is that of Mrs. I. W. T., a large, stout woman, who came to my office early last March on account of failing eyesight. Her appearance and description of her symptoms led me to think that she had albuminuric retinitis; but without any examination, I sent her to Dr. Harlan, who reported that she had unmistakable albuminuric retinitis, and that no local treatment would be of service.

Her urine had, the day of her return to me, a specific gravity of 1020, and with the nitric acid gravity test yielded no cloud, or one so faint that I could not be sure that it existed, and noted, "believed to have a trace of albumen." According to her estimate, she was passing two and one-quarter pints a day.

April 3.—She passed three and a half pints, having a specific gravity of 1010, and totally free from albumen.

21st.—Urine three pints, specific gravity 1015; no albumen.

The symptom of increased arterial pressure and cardiac hypertrophy, upon the diagnostic value of which stress has been laid, afforded in the group of cases here narrated no aid. The patients were all large, stout, middle-aged, married women, with full busts, making the recognition of a slight degree of hypertrophy exceedingly difficult, and the circulation in the two more serious cases was certainly enfeebled.

The practical conclusion to be drawn from these cases is, that reliance cannot be placed upon a single examination of the urine, but that in any doubtful case of chronic disease it is our duty to examine the renal secretion repeatedly, noting whether albumen appears after a heavy meal of flesh, and whether the urine of abstinence is of abnormally low specific gravity. I have seen patients who certainly did not have Bright's disease, but in whom an irritant drug or an alcoholic excess would produce albuminuria. It is to my mind very probable that such people will eventually develop renal disease. At any rate, these cases have suggested to me that possibly, as we employ purgatives to make a so-called therapeutic test in a case of suspected typhoid fever, so we might use cantharides, turpentine, or other irritant drug in a case of suspected Bright's disease. If on trial it should be found that a slight irritation would seriously affect the urine, the case should be looked upon with the greatest suspicion.

MEDICAL PROGRESS.

Atropia in Choloroform Inhalation.—Referring to death by syncope during anæsthesia by chloroform, Poirier refers to the experiments of MM. Dastre and Morat, in which they utilize the known power of belladonna to paralyze the moderator nerves of the heart. Experiments were first made on dogs, and the results obtained were so encouraging that Aubert, Gayet, and Tripier, surgeons, of Lyons, were induced to try it on the human subject, and they obtained gratifying results.

The following solution was employed:

Atropiæ sulph., ...	$\frac{1}{14}$ gr.
Morphiæ hydrochlor., . . .	1½ grs.
Aquæ dest., ...	2½ ʒ.

Hypodermic injection of a Pravaz syringeful was given from twenty to thirty minutes before the inhalation of the chloroform. The advantages of this procedure, which is now daily practised in the hospitals of Lyons, are the following: Security, greater rapidity with which anæsthesia is produced, absolute quiet of the patient, ease with which consciousness returns, and simplicity of results.—*Le Progrès Médical*, Dec. 13, 1884.

The Incubation of Variola.—In an interesting paper on this subject in the *Revue de Médecine*, December, 1884, M. Vinay arrives at the following conclusions:

1. The mean duration of the period of incubation is from eleven to twelve days. It appears to be shorter in the hemorrhagic form, in which it is usually but six or eight days But in the latter, the variations of duration do not bear any relation to the gravity of the disease.

2. Incubation is not prevented, nor its progress modified, by the presence of a preceding febrile disorder. Vaccination alone prevents or modifies the eruption of variola.

3. It is doubtful whether at this period contagion by simple atmospheric media can be caused, but the disease may now be transmitted by inoculations of blood or by vaccination. This last occurrence may result especially during an epidemic of variola. To prevent it, it is preferable to use only animal vaccine, and if it be impossible to obtain this, vaccination from arm to arm should not be practised. It is better to recultivate the vaccine, to keep the vaccinifer under observation, and not use the product within twelve or fifteen days.

4. Not only does vaccination prevent the development of smallpox when it is practised in season, but it also moderates the eruption—lessens it and renders it more benign, even when practised after variolous infection and during the incubation. Success is best assured when it has preceded the appearance of the variolous fever quite a number of days, and is almost *nil* within three or four days. When the fever has appeared, it is useless to resort to vaccination. Whatever the procedure—pricking, scarification, or subcutaneous injection—the progress and severity of the disease are not at all modified.

The Treatment of Ozæna.—Loewenberg, in an instructive article in *L'Union Médicale*, Dec. 2, 1884, on Ozæna, remarks that the discovery of living microbes in the discharges is an indication for energetic parasiticide treatment. To this end he employs:

1. The *nasal douche* with a solution of 1 part (of corrosive sublimate) to 9000 or 10,000 parts of water, gradually increasing the sublimate, so long as the patient can endure it. That the veil of the palate be

elevated during the application, it is recommended that the vowel *a* be sounded.

2. The *nasal bath*, which is accomplished as follows: The douche being completed, the patient inclines the head backwards, so that the nostrils become the most elevated point of the naso-pharyngeal cavities. While in this position, the solution of corrosive sublimate is gradually introduced through one nostril till it is at the point of escaping by the other, the patient all the time breathing through the mouth, or sounding the letter *a*. It is thus made certain that both nasal fossæ are filled, since the fluid in them conforms to the hydrostatic law of communicating vessels.

3. After the douche and nasal bath, the treatment is terminated each day by insufflations of an *impalpable powder of boric acid;* it is necessary to proceed with great care so as to spread the powder uniformly upon the whole interior of the nasal fossæ and upper pharynx, especially when there is much lateral deviation of the septum. The sounding of the letter *a* is here generally recommended to prevent the acid from reaching the larynx.

The results of the above treatment much excel those obtained by the nasal tampon, which is objectionable on account of retaining fetid discharges. The method as indicated above, destroys the fetidity of the discharges, and marked improvement of the general health follows its use.

TREATMENT OF SYPHILIS.—At the International Medical Congress of Copenhagen the treatment of syphilis by hypodermic injections was ably discussed by various members. PROF. LEIBREICH considered formiamide of mercury the best preparation for hypodermic use, since it is extremely soluble and very slightly irritating.

MARTINEAU asserted that by this means the physician is certain to cure all manifestations of syphilis—normal or abnormal. The form of mercury preferred, according to his experience, is the peptonate of mercury and ammonia.

WOLFF (of Strasbourg) used neither the peptonates nor the formiamides, but preferred the following:

1. Carbonate of soda, 23 grains; water, 3½ ounces.
2. Corrosive sublimate, dissolved, 57 grains; water 3½ ounces.
3. Glycocoll, 38 grains; water 3½ ounces.

The glycocoll may be replaced by asparagin or alanin, or, better still, by sarcosin.

Each of the three above preparations is made in a separate bottle, and they are mixed in equal parts at the time of using. Each syringeful of fifteen grains contains exactly one-sixth of a grain of the oxide of mercury. The injection is made two days in succession, the patient being then left one day without treatment. The operation may be repeated twenty-five times without accident.—*Annales de Derm. et de Syphilig.*, Nov. 1884.

DISGUISED FORMS OF MALARIAL POISONING.—In an interesting paper with the above title, DR. F. SIMON, in the *Rivista Clinica de Bologna*, shows the necessity, especially in children, in obscure and serious cases, of holding in mind the possibility of such conditions, and insists upon the efficacy of sulphate of quinine in their treatment after all other remedies have failed. He cites three cases in which the symptoms noticeable were, in one, suffocation, followed by persistent dyspnœa; in another, an intermittent fever and torticollis, manifested twice daily and at regular intervals; in a third, a simple intestinal catarrh, followed by a very profuse, muco-sanguinolent diarrhœa. In every case the administration of quinine was followed by permanent improvement.—*Gaz. Med. di Torino*, Dec. 15, 1884.

THOMSEN'S DISEASE AND PSEUDO-HYPERTROPHIC PARALYSIS.—In the *Archives de Neurologie* of November, 1883, DR. ROMAN VIGOUROUX reaches the following conclusions concerning this disease:

1. The hysterical attacks primarily resemble the advent of common epilepsy.
2. Some cases exceptionally simulate an attack of *le petit mal.*
3. Again the attack resembles partial epilepsy (Jacksonian epilepsy, or epilepsy due to cerebral lesion).
4. False partial epilepsy of a hysterical nature is like partial true epilepsy, characterized either by one-sided spasm with rotation of the body and eyes of the convulsed side, or by monoplegia.
5. Partial epileptoid seizures often constitute the whole attack of hysteria, and are followed neither by marked spasm nor by hallucinations.
6. The approach of false partial epilepsy is shown commonly by a series of attacks followed by a true epileptic condition.
7. The symptoms which enable false partial epilepsy to be diagnosticated from true partial epilepsy are:

a. Absence of pyrexia in false partial epilepsy.

b. Absence of paralysis of the convulsed limbs in false Jacksonian epilepsy.

c. Less significant, but pointing to the hysterical nature of the case, are the opening of the mouth during the approach of the attack, contractions of the eyebrows, and undulatory movements of the belly at the beginning and during the intervals between the crises.

8. Other useful elements of diagnosis are the effects of ovarian compression, failure of potassium bromide, and establishment of permanent symptoms of hysteria after the attack.

ACTION OF HYDROCHLORATE OF COCAINE UPON THE MUCOUS MEMBRANE OF THE PALATE, THROAT, AND LARYNX.—DR. ARTHUR GEIER, in the *Berliner klin. Wochenschrift* of Dec. 15, 1884, in a paper with the above title, calls attention to the following points:

1. The action of cocaine begins in from one to two minutes after its application and lasts about ten or twenty minutes.
2. Before the objective action of cocaine appears, the subjective results are manifested and outlast for a short time the objective.
3. With the remission of the subjective symptoms the characteristic appearance of the mucous membrane returns as it existed before the application of the cocaine.
4. Anæsthesia need not be complete—*i. e.*, touch may be felt even in very sensitive individuals without reflex action being excited.
5. The subjective symptoms exist in the feeling of numbness, dryness, swelling, and in failure to perceive mucus and saliva in the movements of deglutition.
6. The sense of taste is blunted and the sense of

touch abolished, while the sense of temperature remains.

In all the cases the statement was made that the button of the laryngeal sound felt "cold."

Coca and Cocaine.—Coca is the leaf of the erythroxylon coca, of the family Malpighiaceæ, and is a native of Peru. The leaves are the only part of the plant used. The use of the coca leaves is very extensive in Peru, Mexico, and Bolivia. Cocaine is an alkaloidal extract of coca; it was discovered by Niemann in 1860, and carefully studied by Lassen, in 1864, who found a second alkaloid, *hygrine*. Cocaine is solid and crystallizes in prisms of from 4 to 6 sides. It is colorless and odorless; soluble in water and alcohol, and is very soluble in ether. It has an alkaline reaction, and saturates acids to form very soluble salts which, with the exception of the hydrochlorate, crystallize with difficulty.

Ecgonine. If, instead of saturating hydrochloric acid with cocaine, it and the acid be heated to 212° Fahr., in sealed tubes, a new base is obtained, to which Wöhler gave the name ecgonine, benzoic acid and methylic alcohol being formed at the same time—ecgonine is very soluble in water, and insoluble in ether. It has not yet been used in therapeutics.

Niemann gives the following as the process for extracting cocaine: The leaves are digested in 85° alcohol, to which a little sulphuric acid is added. Into this is put a slight excess of milk of lime, and the mixture left standing for a time. The alcoholic liquid is then poured off, neutralized with sulphuric acid, and evaporated to the consistency of an extract. A blackish mass is thus obtained which yields its sulphate of cocaine to water. By precipitating this solution with carbonate of soda, cocaine is obtained, which is purified by being dissolved in ether and then crystallized in alcohol.

Lassen prefers the following method: The leaves are exhausted with cold or slightly warm water; the macerated residue is precipitated by the addition of subacetate of lead, the excess of which is then cautiously removed with carbonate of soda. After filtering, the watery liquid, the reaction of which should be only *slightly* alkaline, is agitated with ether, which dissolves the cocaine. On evaporating this, ether leaves he crude cocaine, or it is purified by dissolving it in water acidulated by hydrochloric acid, and then dialyzing. The hydrochlorate of cocaine passes rapidly through the septum, and is precipitated with carbonate of soda. One kilogramme of leaves yields about two grammes of cocaine.

Hygrine is another alkaloid found by Lassen in coca leaves. It may be obtained from the watery fluid from which cocaine is separated by shaking up with ether. To this fluid an excess of carbonate of soda is added; the lime salts are precipitated and hygrine liberated. It is then obtained by shaking up with ether, and a brown, slightly alkaline liquid is obtained by evaporation. Hygrine is a liquid and volatile alkaloid, with a strong odor of trimethylamine, and forms crystallizable salts with acids.—*Progrès Méd.*, Dec. 13, 1884.

Thallin.—The industry of continental chemists in the application of the synthetical methods to the formation of new compounds has brought to light a new antipyretic agent, which appears to have been used successfully in a large number of cases in the clinic of Prof. Nothnagel. It has the constitution of a secondary chinoline base, being one of a number of chinoline derivatives prepared by Prof. Skraup, and is represented by the systemic name, "tetrahydroparachinanisol." The salts of this base, which have an acid reaction, are freely soluble in water, and have the property of forming green compounds when treated with solution of ferric chloride and oxidizing agents. On account of this peculiarity, the cumbrous systemic name has been dropped in favor of the shorter designation, "thallin." The hydrochlorate, sulphate, and tartrate of thallin and the hydrochlorate of ethyl thallin are the salts that have been employed, and these are said to show great antipyretic activity in doses of quarter, half, and three-quarters of a gramme, a point in which thallin would seem to compare favorably with some of its competitors. The lowering of the temperature is said to take place gradually and to last a considerable time, whilst it is not accompanied by any secondary disturbances. Thallin can be conveniently administered in wafers containing a quarter or half of a gramme of the sulphate. Two other chinoline derivatives have been experimented with; one of them has but slight antipyretic properties, while the other was fatal to guinea-pigs in doses of from 2 to 6 grammes, violent tetanic seizures being excited.—*Lancet*, Dec. 6, 1884.

Cocaine as a Urethral Anæsthetic.—Dr. A. Blumenfeld, in a preliminary note on this subject, reports having used cocaine for producing anæsthesia of the male and female urethra. He first used it in cases in which catheterism was painful, injecting ♏ xxx–xlv of a two per cent. solution into the urethra by means of a small syringe, and the fluid retained by pressure with the fingers for three or four minutes. In every case the injection produced a diminution of sensibility, and often complete anæsthesia of the whole urethra, as far back as the neck of the bladder. The anæsthesia persists for half an hour, and may be kept up longer by a second injection or by a stronger solution.—*Deutsche med. Wochenschrift*, December 11, 1884.

Physiological Action of Bromoform.—Von Horoch reports that his experiments on animals with bromoform, administered subcutaneously, by the stomach, or by inhalation, show that this drug is a general anæsthetic. The respiration is not notably influenced; the pulse continues strong and of normal frequence; and the peripheral ends of the vagus retain their irritability. The blood-pressure falls during narcosis, but rises again with the discontinuance of it. The irritability of the vaso-motor centre is lessened, and the reflex irritability is entirely lost.

Administered hypodermatically, a comparatively small dose causes deep and lasting narcosis; due, not so much to the size of the dose, as to the ease with which the drug is absorbed. Von Horoch has had no case of abscess at the seat of injection, nor any noticeable irritation from it. He has not given it to the human subject by inhalation, but it does not cause vomiting in animals. The vapors cause considerable irritation of the conjunctiva.—*Centralbl. f. d. med. Wissensch.*, Oct. 25, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JANUARY 10, 1885.

PEPTONURIA IN THE PUERPERAL STATE.

WHILE the true significance of peptonuria is as yet undetermined, there is no doubt that it plays a part in a large number of processes, the majority of which are pathological. Recently DR. WILLIAM FISCHEL has published, in the *Centralblatt für Gynekologie*, Nov. 11, 1884, some investigations on the occurrence of peptonuria in puerperal women, and has found that peptone is present in the urine in a large percentage of cases. Thus, in 156 tests of urine from 56 lying-in women, he found peptonuria 86 times. During labor and the twelve hours immediately succeeding it, he found no peptone. During the second and third day peptonuria is almost constantly present, having been found in 24 out of 25 examinations. From the fourth to the sixth day it was found in 37 out of 44 examinations; from the seventh to the tenth day in half the specimens examined. After that time there were two doubtful reactions, but peptonuria could not be asserted.

Eliminating all but the most typically physiological cases, there still remain 15 primiparæ and 25 multiparæ in whom peptonuria was found in about the above proportion. It occurred with living and still-born, full-term and premature births, and disappeared more rapidly the more rapid the involution. In contrast to this the urine in a case of Porro's operation, examined for six days after the operation contained no peptone.

In seeking for the source of such a peptonuria it is to be remembered that Hofmeister has shown that it attends inflammatory and suppurative processes, and that, therefore, suppuration about the external or internal genitalia may be responsible for it in puerperal women. But Fischel ascertained that in his cases the external genitalia, at least, might be excluded with certainty, as these furnished in the primiparæ the most trifling, and in multiparæ absolutely no abrasions, and still less suppuration. Fischel himself learned that the lochia frequently contain peptone, but ascertained that during the second and third day it was seldom present in them, while the urine examined at this time always contained it. That the leucocytes in the puerperal uterus were also not responsible for the peptonuria seems likely, from the fact that their number is immensely less than in an inflamed lung, accompanying which the peptonuria is much less marked than that in the puerperal state.

Fischel is forced, therefore, to the conclusion that under certain circumstances the fatty degeneration of the muscular fibres, which forms a part of the process of involution of the uterus, is attended with the conversion of muscle albumen into peptone. Certainly in the substance of the fresh puerperal uterus, and almost exclusively in the muscular element, peptones are found. This Fischel has confirmed by the study of fresh specimens derived partly from operations—the hyperplastic uterus of tumors—and partly from rabbits killed sixteen and forty hours after delivery. On the other hand, he found no peptones in the non-pregnant uteri of animals, nor in pregnant uteri which had not undergone contraction. In a single instance only did he find peptone in the endometrium.

With a view to comparing this condition with analogous ones, Fischel produced experimentally phosphorus poisoning, thinking that the fatty degeneration induced by it in the albuminous tissues would afford an analogy to the fatty degeneration of the puerperal uterus and result also, perhaps, in an analogous peptone formation. In nine experiments he found peptone in several organs, of which two were tissues which, in the normal animal, never contain peptone, viz., the liver and striated muscular tissue. It was found in organs which had not as yet undergone fatty degeneration. Fischel also examined the urine of pregnant women for peptone, and found it in one-fourth of the sixty-eight investigated. With regard to its cause under these circumstances, he only ventures to suggest that it cannot have anything to do with internal suppuration, and that it may be due to contractions of the muscular structure of the pregnant uterus.

DR. OTTO KÜSTNER reports, in *Centralblatt für Gynäkologie*, November 22d, a case of peptonuria incident to rupture of an ovarian tumor into the abdominal cavity. The patient came under observation July 21st, and the next day, during an examination of the case while under ether, the sac was burst.

The urine of that and the next day, amounting to but 300 grammes, contained only a trace of peptone; on the third day, however, after the rupture, the urine gave a decided reaction with phosphortungstic acid.

The explanation furnished is that there are always peptones in the contents of such cysts; but there is no absorption of the peptones from the contents of the unruptured cyst, because of the poverty of blood-vessels in its walls. But should a cyst rupture into the abdominal cavity, the peptones are immediately absorbed, and secreted by the kidneys, peptonuria being the result, as soon as the quantity of peptones in the blood reaches a certain amount.

The intensity of the peptone reaction is always proportionate to the rapidity of the absorption of the peptone-charged fluid. The diagnostic application of this observation is found in the fact that, after the rupture of the cyst, percussion revealed practically no diminution in the area of dulness. Hence, in case of ovarian cyst, it may be inferred that the sac has ruptured, if peptonuria suddenly appear.

SUPERFŒTATION.

In resuming the consideration of that variety of superimpregnation known as superfœtation, it may be remarked that ancient authorities, among whom may be mentioned Hippocrates and Aristotle, fully believed in the doctrine. Daremberg has stated that Aristotle derived from Homer his belief in the viability of the fœtus at seven months, an example of the birth of a living child at that time having been given by the Greek poet, in the nineteenth book of the Iliad, in which Juno is asserted to have induced premature labor in Sthenelus's wife "scarce seven moons gone." It seems quite as probable that the father of medicine found in one of the versions of the story of Antiope ground for his faith in superfœtation. This beautiful maiden becoming pregnant by Jupiter, was driven from her father's house, and kindly received by Epopeus; she gave birth to male twins, one of them, Amphion, who was said to be the son of Jupiter, while the other, Zethus, was the son of Epopeus; certainly the two differed so greatly in character that one might readily believe they had different fathers.

It is more probable, however, that Hippocrates and other ancient authorities believed the doctrine of superfœtation from their ignorance of the true form of the womb in the human female, regarding it double as they had seen it in so many of the inferior animals. Now it so happens that in some of the cases in which superfœtation has been alleged, duplicity of the uterus was proved to be present, arrest of development having occurred, so that this organ retained a temporary form in the human female, but the permanent form of inferior animals. It certainly would seem to be much more probable that superfœtation would occur in a case in which the womb was double than where it is single; since in such a case the mechanical obstacle to the entrance of the spermatozoids and their ascension in the uterus which, after a certain period of pregnancy presents an impassable barrier, is not present, for of course the second half of the uterine cavity has not undergone the changes consequent upon pregnancy. It must be obvious that if superfœtation were possible, or at least if there were not very great obstacles to it, multiple pregnancy would become the rule rather than the exception, since woman is less favored than animals, who are exempt from sexual intercourse during pregnancy.

The presence of the cervical plug of mucus, which was supposed to be formed just after the beginning and remain until the end of pregnancy, may be rejected as an inconstant phenomenon, or, if present, furnishing no serious obstacle to the ascension of spermatozoids.

Union between the decidua of the ovum and that of the uterus—the decidua reflexa and the decidua vera, according to the Hunterian theory—does present an insuperable barrier to the passage of spermatozoids. According to Robin and most authorities this union occurs in the fourth month, while Schrœder gives the sixth month. It is thus seen that there is no anatomical obstacle to superfœtation prior to the fourth month at least.

The strongest argument against superfœtation is that which rests upon the suspension of ovulation during pregnancy. As the hen when hatching does not lay eggs, so the human female when carrying on a process of internal incubation does not ovulate. Almost all physiologists are agreed upon this point. Playfair, indeed, asserts that menstruation in pregnancy proves ovulation; but Dolèris justly suggests that menstruation after double ovariotomy would then prove the same thing. With Stoltz we believe that no true menstruation occurs in pregnancy, and that all discharges of blood from the uterus in such condition, even if observed periodically, are simply threatenings of abortion, or of premature labor, and should be so treated. Matthews Duncan claims that there is no anatomical reason, during the first three months of pregnancy, why the ordinary menstrual flow should not proceed from the body of the womb, and Panum (*Nord. med. Ark.*, 1882) believes that ovulation does not cease until two or three months after the pregnancy begins. It may be answered that when a woman becomes pregnant nature's vow has been fulfilled, and therefore there is no necessity for the maturing and discharge of other ovules, since single not multiple pregnancy is the law of the human race. Nature does nothing in vain was the axiom of Aristotle, but surely it would be in vain in

almost all cases for ovulation to continue during pregnancy, or any part of it. Schroeder asserts that there is not a single well proved example of the expulsion of an ovule during pregnancy; the same statement is made by Doléris.

We may, therefore, conclude from this brief review that while superfœtation is not impossible, it is in the highest degree improbable. The cases that have been adduced in its favor are either too remote from our times, or too imperfectly reported, or admit of other explanation: some of them seem in part fictions rather than facts. Time fails us to analyze the different cases on record, and show the correctness of our statement.

Most of the cases of multiple pregnancy are doubtless the result not of superfœtation, not, indeed, of superfecundation, but of simultaneous fecundation. It is probable that at each seminal ejaculation a large enough number of spermatozoids is discharged to fecundate hundreds of ovules; nature makes ample provision, probably no less in the male than in the female element, to secure the continuance of the race.

Referring now for a moment, in conclusion, to Dr. Wagner's case of quadruplets, referred to in the last number of The News, was one of the quadruplets conceived a month before the others, or, in other words, was this a case of superfœtation? The arguments in favor of this hypothesis are the greater size, weight, and vitality of one of the children—in a word, its better development. We answer—first, it is rare that even in twin pregnancy the children are equal in size and weight. A similar fact is observed in those domestic animals which produce many at a birth; thus it is common in a litter of pigs especially, to find one very much smaller and feebler than any of its brothers and sisters, and it is commonly called a runt. But no one in such cases attributes inferiority of size to superfecundation, still less to superfœtation.

Again, the difference in favor of the largest of the four children was half a pound in weight and one inch in length. Now, supposing the pregnancy to have begun in November, it ought to have ended about the 12th of August; but it ended the 22d of July, some three weeks sooner than it should have done, and as is well known even in cases of twins, still more in quadruplets, premature labor is the rule. Admitting, for argument sake, that the largest child was conceived in November, the other three in December, and that the former was born at eight, the others at seven months, did half a pound in weight and one inch in length correspond with one month of development? It is fair to state that the increase in the supposed time ought to have been from one to two inches in length and about two pounds in weight.

While, then, possibly superfœtation might have occurred in this case, we must regard it as very doubtful.

A STATE BOARD OF HEALTH AT LAST!

We are glad to learn that a renewed effort is now being made in Pennsylvania to establish a State Board of Health, and so wipe out the disgrace which attaches to this State from the fact that whilst twenty-seven States have organized protection for the health of their people, Pennsylvania and Ohio are as yet unprovided with active boards of health, and are the only important Commonwealths in the Union so destitute. Moreover, if the proposed law for a National Board of Health be enacted, this State will suffer under the disadvantage of not being entitled to representation in that organization. A conference of delegates from various local organizations has been called to meet in Harrisburg on the 13th of January, when it is to be hoped that the powerful arguments in favor of creating a State Board of Health will be so cogently presented before the Legislature as to secure the passage of the requisite Act, and a grant of the paltry appropriation needful to vitalize its provisions. The appeal is more worthy of attention and immediate action at the present time than hitherto, in view of the prospect that cholera, following its usual course in former visitations, will make its appearance upon our shores early next summer. Then, unless active and systematic measures to prevent its spread are enforced over the whole State, it will inevitably entail upon us a vast amount of suffering and death, to say nothing of the pecuniary losses which must infallibly result from its epidemic prevalence.

The outbreak of smallpox in 1872–73 is estimated, by a highly competent observer, to have cost the city of Philadelphia, directly and indirectly, several millions of dollars, and the mere rumor of a probable extension of epidemic cholera unchecked, in Pennsylvania, would involve a loss of trade from fleeing citizens, as took place in Marseilles and Toulon last year, which might readily amount to a hundred or perhaps a thousand-fold the sum required for maintaining an efficient State Board of Health. In 1879 the report of a single case of yellow fever in the South caused a shrinkage of values in the Chicago provision market amounting to one million of dollars in twenty-four hours.

One of the most conclusive arguments against the cavillers, who dispute the efficacy of systematized sanitary precautions in controlling the spread of disease, is to be found in the experience of New York during the visitation of cholera in 1866. According to the official report, upwards of a thousand cases of cholera then occurred in numerous localities more or less widely separated; and in order to prevent the spread of the malady, a well-appointed disinfecting

corps was organized, and arrangements made for squads to respond instantly to any call, either by day or night. They were provided with every requisite, and with means of transportation to secure immediate service; and the beneficial effect of their labors is shown by the statement, that in three hundred and sixty-two New York houses, where individual families or persons were smitten by cholera, but which were promptly brought under sanitary control by disinfection and local purification, the pestilence did not extend beyond the family in which the first case occurred.

CHOLECYSTENTEROSTOMY.

From a series of experiments conducted upon dogs in August, 1884, Dr. Gaston, of Atlanta, demonstrated the feasibility of establishing a communication between the gall-bladder and the duodenum—an operation which he suggests should be performed upon the human subject in preference to cholecystotomy in cases of closure of the ductus communis choledochus. The paper, which is a most interesting contribution to our knowledge of obstruction of the duct, may be found in *Gaillard's Medical Journal* for October, 1884.

In his comments upon Dr. Gaston's proposition to divert the bile directly into the duodenum, its editor states that the "great, novel, and original operation" should be known as that of Gaston. If he will, however, turn to the *Prager med. Wochenschrift*, Nos. 21 and 22, 1882, he will find that, in a case of closure of the choledoch duct of a woman thirty-four years of age, Von Winiwarter successfully performed the operation which Gaston practised in dogs. Hence any "honor and distinction" which the ingenious and rational procedure may merit, must be awarded to Von Winiwarter, and not to Gaston.

THE BACILLI OF THE MOUTH.

No more fertile source for bacteria, available to all who care to study them, can be found than the cavity of the mouth. W. D. Miller states, in the *Deutsche med. Wochenschrift* for November 27th, that if a sharp instrument be introduced between the gum and a tooth, especially if the former be from any cause slightly hyperæmic, the scrapings thus obtained leave nothing to be desired in the way of curved bacilli and spirochætæ.

In the first place, there is a comma-bacillus resembling that of cholera, but which Koch has shown to be altogether distinct. No efforts to cultivate it have as yet succeeded. A second fungus, less difficult to cultivate, is a short, plump, somewhat pointed bacterium, of which two are often united at an acute angle. The latter especially occur with rods which are in a state of fission. The fungus is mobile, growing very rapidly at the temperature of the room, and liquefies gelatine to a considerable extent. A third fungus is also a delicate rod, either straight or more or less curved, sometimes to the extent of a semicircle, so that two placed appropriately produce an O-shaped figure, and sometimes the rodlets are so rolled together that they can scarcely be distinguished from coccospheres. By fission they form coccochains, best seen in old cultures. In these Miller has found neither spore formation nor motion. They are very slow and difficult of culture on gelatine, but do not cause a liquefaction of this substance. Hence, it differs in this respect from the cholera fungus.

Miller has also found, in the mouth, fungi which are not destroyed by an artificial gastric juice, and these may pass through the stomach into the intestine, and there undergo further development. This may be true of these curved bacilli described, since he has found in his own feces undoubted curved bacilli, especially accompanying a slight diarrhœa. But these were as difficult of culture as the curved bacilli found in the mouth. Whence we may infer that the fact of a bacillus being curved is no criterion of its specificity, and that bacteria of this shape occur which have no closer relation to each other than the different bacteria which are found in the shape of cocci. Much more accurate information may, however, be expected from carefully conducted culture experiments.

DRAINAGE OF CEREBRAL ABSCESS.

In The Medical News for August 2, 1884, we called attention to the subject of drainage of abscess of the brain, and stated that up to that time only three cases had been recorded, all of which recovered, the operators having been Burchard, Fluhrer, and Fenger and Lee. In looking over the *American Journal of the Medical Sciences*, we find in the number for July, 1882, that in a remarkable case of lodgement of the breechpin of a gun in the cranium, Dr. Noyes made free provision for the escape of pus from an abscess which subsequently formed in the frontal lobe of the brain, a drainage-tube having been passed by the trephine hole through the cavity and out of the orbit. Death, however, ensued from basal encephalitis.

Unless we greatly mistake, Dr. Noyes led the way on this side of the Atlantic in draining a cerebral abscess; but the first operation of the kind must be credited to Burchard, whose case is published in the *Deutsche Zeitschrift für Chirurgie*, Bd. xv., 1881.

In this connection, we may call attention to the successful extraction of a breechpin from the brain by Dr. Kemper, which is recorded in the *American Journal of the Medical Sciences* for January, 1885. In this case, drainage was also resorted to, thereby showing the great superiority of the new over the old plan of managing such lesions.

SOCIETY PROCEEDINGS.

PHILADELPHIA ACADEMY OF SURGERY.

Stated Meeting, December 1, 1884.

THE VICE-PRESIDENT, S. W. GROSS, M.D., IN THE CHAIR.

DR. W. W. KEEN read a paper on

COMBINED TUBULAR AND CAPILLARY DRAINAGE OF LARGE WOUNDS.

The great practical importance of the subject of drainage, he said, leads me to make a few remarks this evening in relation to its use in large wounds.

The *methods* may be divided into two—first by tubes, and secondly by capillary action; and the *materials* vary in each. I reject the older mode by tents and their equivalents, as with modern antiseptic methods they are practically abandoned. For modern surgery demands that we shall strive for union by first intention and without suppuration—results unattainable by the older means just named.

The tubes employed are either rubber (usually fenestrated) or of decalcified bone. They have one marked advantage, viz., their large calibre and free discharge. Hence they are especially fitted for securing the escape of the more abundant oozing following all large operations or after opening large abscesses. I always keep several feet of such tubing in a bottle of carbolized water (five per cent.), and have not found any septic results from their use. They have, however, the disadvantage that if exposed to pressure, as in a joint, their calibre is obliterated. The decalcified bone sometimes is not aseptic and not seldom softens and collapses, especially if kept in carbolized oil. Keeping them in glycerine and alcohol or in the bichloride solution and alcohol often prevents this. But even then, within a week, they dissolve and no longer act as drains.

The second method is by capillary action. For this purpose either horsehair or catgut or rubber threads are used. They answer well in case the liquid to be drained is thin, but if thick and glairy they fail to act and are useless. Of the three, on the whole, I prefer horsehair (which, after washing, I always keep in carbolized water as above), as it is equally unirritating, can always be had, is strong, is not absorbed as the catgut is, and allows the granulations to grow in between its threads.

My special object, however, is to bring before the Academy a method I have used for some seven or eight years which unites the advantages and avoids the dangers of both methods. The chief advantage of the tubing is its free discharge. Its disadvantage, in addition to that noted above, is that if used for any length of time, when removed, it leaves a tubular passage of considerable calibre lined with granulations. This passage if long, as in large wounds, is often apt to close at two or more points in its course, thus penning up the slight discharge and producing retention and suppuration. The disadvantage of the capillary drainage is that it is not fitted to give exit to large amounts of fluid. Its advantage is that it leaves no such tubular passage, but that while giving us the means of introducing tubing for freer drainage, if at any time it is needed, it allows nearly complete healing, even while a few of its strands are still *in situ*. Especially is this of value in larger wounds with long drainage paths.

The method referred to is as follows: When the wound is ready to be closed, a fenestrated rubber drainage-tube and a bundle of horsehair of fifteen to thirty or more strands are both placed side by side in the wound. At the end of twenty-four or forty-eight hours the abundant oozing of bloody serum usually necessitates a redressing, but by this time the first abundant discharge has ceased. Accordingly at the first dressing after the operation I remove the rubber tube, leaving the horsehair in place. If the oozing will probably be small, I often even remove a large part of the horsehair. At the second dressing, say in three to six days, I remove all the horsehair or all but two or three strands. In doing so I always remove the hairs one or two at a time, as the nice adjustments of the surfaces is thus scarcely at all disturbed. At the third dressing, if all has gone well, the last horsehairs are removed and the capillary passage heals within twenty-four hours.

For joints or in other wounds where possible longer slight discharge may take place, the horsehair may be left for longer periods as judgment dictates.

I have used this method in amputation of the breast, often bringing tubing and horsehair out through a button-hole counter-opening in the axilla and treating it as described above. I have used it in a large number of amputations of the upper and lower extremities and in the removal of tumors of the neck and other parts of the body and find it to work admirably.

The same result may be attained by first using the tubing alone, and replacing it at the first redressing by the horsehair, but the pain and the mechanical disturbance of the wound are so much greater than the method above described that I have never found it to answer as well.

Of course for small wounds, only the horsehair is required.

While speaking especially of rubber tubing and horsehair, this method of combined drainage will answer equally well with any of the other materials mentioned, and it is to the method that I particularly design to call attention rather than to the material used.

DR. J. EWING MEARS said that the objection to the rubber tube is, as has been stated, that it leaves a canal lined with lymph, which may close at different points, preventing the escape of fluid. There is one method which had not been referred to. It consists in introducing a decalcified bone drainage-tube, within which has been placed a number of horsehairs. The hairs are removed one by one. This prevents the collapse of the tube, but does not overcome the objection to the presence of the tube in the wound.

He had frequently practised Dr. Keen's method in the St. Mary's Hospital, where it is in general use, and he knows that it works admirably in the deep wounds met with in hospital practice.

There are, of course, certain objections to the presence of the tubes in wounds, in that they interfere with the reparative processes and prevent union by the first intention. At the same time, however, the advantages gained can scarcely be counterbalanced.

DR. J. M. BARTON said that he had been in the habit of using, in the case of wounds where there are two openings, a rubber drainage-tube, inside of which is

placed a number of rubber threads. When ready to remove the larger tube, the small threads are held securely and the tube drawn off. When there is no counter-opening, it is always difficult to retain the tube in position, and when the tube is removed it is difficult to replace it. In order to facilitate the introduction of the tube under such circumstances, he had recently had the ordinary probe of the pocket-case modified. The sharp, triangular end of the probe has been blunted and a little spur placed at a short distance from its extremity. When inserted into one of the openings of the tube, this spur prevents its passage into the tube.

DR. O. H. ALLIS asked Dr. Keen whether he had ever used fine silk in place of horsehair?

DR. KEEN said that he had never used the silk, although of course it would, in many respects, answer as well as the horsehair. He thought that when a number of threads are made into a strand by twisting, as in the case of a silk thread, the capillary action is not as good as in the horsehair, and the strands are apt to mat together if the discharge be thick. If used at all, it should of course be kept in an antiseptic solution.

In the case of wounds with a single opening, he takes the requisite number of hairs and doubles them in the shape of a hairpin. After the loop is introduced through the external opening, the hairs have enough stiffness to permit of their being readily pushed to the bottom of the wound. Of course, in attempting to remove a portion of the mesh, all of it may be pulled out, but in such a case it is a simple matter to introduce a smaller mesh.

DR. MEARS asked if Dr. Keen had had any experience in the use of catgut threads in the drainage of deep wounds?

DR. KEEN replied that he had, but the hair is so much superior that he had used it almost exclusively. Catgut swells, and it may obstruct, instead of facilitating, the escape of the discharge. Horsehair does not undergo such a change, and is much more permanent.

DR. DE FORREST WILLARD had found the same objections to catgut. It also seems to hold the pus, and not carry it out. He thought that we are apt to leave the rubber tubes in too long, so that they act as setons. If the tube is removed gradually, healing may not occur as rapidly as the tube is removed, and accumulation of pus may take place behind it. In order to have free drainage after amputations, he inserts between each stitch a short piece of rubber tubing. These are removed at the first dressing. There is a caution to be given in regard to this plan in cases in which there are redundant skin flaps, and that is that there is danger of one of the tubes slipping out of sight.

DR. O. H. ALLIS remarked, in regard to capillary action, that a silk thread must have a more powerful action than horsehair; which could be proved by inserting a silk thread and a horsehair into a tumbler of water. The silk would take up the water more quickly than the horsehair. Two hairs, placed side by side, would have greater action than one, and three braided together would have still more powerful effect. I have had good reason to continue the use of single threads passed through the wound in different directions.

DR. MEARS asked the question, in regard to the use of catgut, because it has been claimed that great advantages have been derived from the use of tubes which are absorbable, such as the decalcified bone drainage-tubes. He thought, however, that the judgment of many surgeons is adverse to their use, because they often undergo absorption too rapidly. It is said that immersion in alcohol renders them more resisting.

DR. S. W. GROSS thought that Dr. Keen's remarks in regard to the use of horsehair are capable of a wide range of application. He had used decalcified bone, and he had been more disappointed with it than with anything else that he has tried in surgery. They absorb the fluids, become soft, and collapse. If soaked in alcohol, they become stiff, and are, to a certain extent, rendered unabsorbable. Some time ago, he removed from a man's axilla a number of caseous tubercular glands, and put in a decalcified bone drainage-tube, attaching it to the edges of the incision with catgut ligatures. Seven days later, when the dressing was removed, it was found that healing had taken place, and that the catgut ligatures and the tube had disappeared. Four months later, the man returned with an opening in the axilla, which was supposed by some to be due to some of the glands having been overlooked. He passed a pair of forceps into the opening, and drew out the bone drainage-tube, which had not undergone the slightest change. Looking up the literature of the subject, he found a case described in which, for the cure of hydrocele, the sac was incised antiseptically, and a decalcified bone-tube introduced. Fifteen months later, the tube was removed unchanged. It follows from this experience that no reliance can be placed on these tubes. He uses exclusively the red rubber drainage-tubes, which he considers better than the black.

He thought that horsehairs can be utilized to such an extent as to enable us to do away almost entirely with the use of rubber tubes. In large wounds hereafter, he should introduce a drainage-tube and a loop of horsehairs, and at the first dressing remove the large tube, allowing the hair to remain. The same thing can be done in the stump after amputation. A number of hairs may be put transversely, and a few be put between the stitches. When the rubber tube is used, he saw no necessity for leaving it after the first serous discharge has ceased; for where a case is being treated aseptically, pus, even if it should form, will be aseptic pus.

DR. PACKARD called attention to a question which had been asked in regard to

THE BEVELLED INCISION.

All have seen the large leather belts used in machinery. The ends of these are joined by a process termed scarfing, which consists in bevelling the two ends of the belt and bringing them in contact in such a way that the joining will not be thicker than the rest of the belt. He has measured some of these scarvets which were twenty inches long. This adds much to the strength of the joint. Some ten years ago, he was called to a patient who had fallen while carrying a piece of china, and cut the back of her hand from the knuckle to the wrist. The skin had been divided in a slanting direction, so that there was a large surface of partially divided skin. He brought the two surfaces together, and found that they could be brought in accurate approximation. The wound healed, and left scarcely a trace. This led him to think that such an incision could be made use of in surgical operations, and he decided to try it at the first

opportunity. The first case in which he employed it was in operating on a bursa over the patella. He made an oblique incision, although not nearly so much so as he now employs; and after the wound had healed, he could scarcely find the scar. In all those cases in which it is desirable to avoid a scar, this incision will be of service. It also facilitates healing, and, as all pressure made upon such an incision tends to close it the more, the air is excluded, and an antiseptic effect is obtained. After the operation for strangulated hernia, a truss can be applied much earlier than where the vertical incision is employed, for the irritation of the skin will not be so marked.

CHICAGO GYNECOLOGICAL SOCIETY.

Stated Meeting, December 19, 1884.

THE PRESIDENT, H. P. MERRIMAN, M.D., IN THE CHAIR.

DR. W. H. BYFORD read a paper entitled

A CASE OF MURAL PREGNANCY.

The history was obscure. The patient, who was twenty-eight years old, had been married seven years, and had one child, six years old. She thought that she became pregnant, for the second time, in February, 1883. In April, she became fatigued and had hemorrhages, which continued until May 9th—about four weeks. October 14th, a discharge of yellow fluid, about one gallon in quantity, occurred. A putrescent, sero-sanguineous discharge followed, continuing three months. January, 1884, a large, brownish mass, with very fetid odor, was expelled. After this event, menstruation occurred until July. In May she was quite large, and had bearing-down pains. She entered the hospital October 6, 1884. She was tapped October 18th, and about four quarts of thick, tenacious fluid, resembling the fluid of an ovarian cyst, was removed. This fluid coagulated, on the addition of nitric acid, and on boiling. Assisted by Dr. R. Filley, a microscopical examination was made, with negative results. The "Drysdale" cell was not found. Laparotomy was performed, and a fœtus with placenta was removed without hemorrhage or difficulty. In order to secure perfect drainage, it was considered best to remove the uterus. The operation was performed on October 30th. The patient did not react, but died within twenty-four hours. Prior to the operation the patient was extremely reduced by her protracted sufferings. Dr. Byford, in a similar case at the present time, would elect the vaginal operation. The specimens removed from the woman were exhibited as supporting the diagnosis of mural pregnancy.

This was the second case of mural pregnancy that had come under the reader's observation within a period of five years. In the first case reported to the Society the patient was in labor and moribund when Dr. Byford saw her. She had been in labor until exhausted. There was no difficulty in making a diagnosis. The head was low down in the pelvis, almost on the perineum. The os uteri was well-nigh inaccessible behind and above the symphysis. The body of the uterus, somewhat enlarged, could be felt in the lower and anterior part of the abdomen, attached to the tumor containing the fœtus. The fœtus could be felt through the abdominal walls, surrounded by a thick involucrum, apparently as thick as the uterine walls. Fœtal extremities could be distinguished. When dissected, the sac in which the fœtus was contained was found to contain a thick layer of muscular fibres. These fibres were directly continuous with those of the uterus. The tubes and ovaries lay on either side of the lower portion of the sac. The fecundated ovum had made its way down the tube, became lodged in a diverticulum in the uterine wall, and from this point of departure was gradually extruded into the cavity of the abdomen. The fœtus was thus developed within the uterus, though not within the uterine cavity. The resemblance to normal pregnancy is great, in the presentation and position of the fœtus, deep down in the pelvic cavity, behind the vagina. The head, in this case, was fixed by the concentric contraction of the uterine fibres by which it was surrounded, and could be easily outlined as it lay there covered by the posterior vaginal wall.

The specimen presented is much less perfect than the one described because of the numerous effects wrought upon it, during the great length of time it remained in the maternal body, and the mutilation consequent upon enucleation.

The treatment of these cases ought to be considered apart from that of extrauterine pregnancy at term. It is always a matter for special consideration, in connection with each case, as it presents itself, whether or no the removal of the fœtus, at term, in extrauterine gestation, should be attempted. The dangers of laparotomy are greatly increased by the inability to remove the placenta. The surface to which it is attached has no contractile power, so that the divided vessels are left patulous. If hemorrhage does not immediately prove fatal, the blood is a source of sepsis, that must almost certainly destroy the patient. Laparotomy would more likely prove successful if performed some days after the death of the child. In these cases of ectopic or interstitial uterine pregnancy the fœtus may be easily removed through the vagina. An incision made through the posterior vaginal wall would completely uncover the presenting part, and enable one to apply the forceps, or attack it with the perforator and crotchet, as in ordinary labor. After the removal of the fœtus the placenta should be allowed to separate spontaneously. Since writing this report, Dr. Byford has seen a case, reported in the *Annales de Gynecologie*, July, 1884, occurring in the practice of Mr. Matheson, of England, illustrative of the execution of this plan. The case was reported to the London Obstetrical Society under the title, "Extrauterine Pregnancy; the Extraction of a Living Fœtus through the Vagina." The child was slightly asphyxiated, but survived. A sponge, saturated with perchloride of iron, was introduced into the sac after removal of the placenta. The mother recovered. It would seem that the author did not suspect his case to be one of interstitial pregnancy. During the discussion that followed only one of those present expressed the opinion that it was of that variety. Mr. Griffith thought it was either interstitial pregnancy or one in which the fœtus was developed in one portion of a double uterus.

DR. EDWARD SAWYER thought that interstitial pregnancy meant the development of the ovum in the uterine portion of one of the tubes. In Dr. Byford's

case the uterine portions of the tubes were not involved. It reminded him of a case he had seen near Denver. In this case a secondary uterus, with muscular walls, had been developed, but as the tubes were not involved he did not feel justified in designating the case one of interstitial pregnancy.

Dr. D. T. Nelson said, with reference to the treatment of the placenta, that Dr. Byford's advice was that usually recommended in the text-books. The placenta should be left alone in those cases in which the walls of the secondary uterus were not muscular. He had seen a case, in the museum of the Chicago Medical College, in which no muscular fibre could be detected in the walls. When the walls of the adventitious uterus were muscular it was questionable whether or no the placenta should be left alone. If the placenta is removed, there is danger of hemorrhage; if the placenta remains, there is danger of sepsis. When there was reason to suppose that contractions of the adventitious uterus would check hemorrhage, he thought the placenta should be removed. He had had no experience in these cases.

Dr. E. C. Dudley said that women, in cases of extra-uterine pregnancy, in which the placenta has been allowed to remain, do not die of sepsis. He had seen two or three cases in which the sac had been united to the abdominal incision. Whenever evidence of sepsis occurred, the sac was washed out and the temperature immediately fell to the normal. The placenta, under these circumstances, is spontaneously eliminated in about three weeks. It required phenomenal powers of diagnosis to tell in the concrete case whether or no the sac had sufficient muscular fibres to prevent hemorrhage. The placenta should be permitted to remain within the sac.

Dr. J. H. Etheridge thought that if, on microscopical examination, it was found that the muscular fibres of the normal uterus were continuous with those of the adventitious uterus, the case was one of mural pregnancy. In cases of abdominal pregnancy, there was a line of demarcation between the normal and adventitious uterus.

Dr. A. Reeves Jackson thought, however, with Dr. Sawyer, that the results of the anatomical investigation did not support the author's diagnosis. The uterine portions of the tubes were not involved. So valuable a specimen deserved very close microscopical and macroscopical examination. It ought to be referred to a competent pathological anatomist.

Dr. John Bartlett thought the ovum had not passed through the tube, but had been developed in the broad ligament, beneath the peritoneum, and had, in this manner, derived muscular fibres from the uterus.

Dr. W. W. Jaggard referred to the fact that, next to ovarian pregnancy, interstitial pregnancy was of most infrequent occurrence. Up to the present time about thirty cases, in regard to which the diagnosis was positive, had been reported. Interstitial or mural pregnancy included other sites of development than the uterine portions of the tubes. Dr. Gilbert's case, reported in the *Boston Medical and Surgical Journal*, March 3, 1877, and referred to by Prof. Lusk in his treatise on *Midwifery*, was a case in point. The ovum in this case was developed in what seemed to be a bifurcation of the Fallopian tube. In Dr. Byford's case the tubo-uterine orifices were not involved. The sac was extrinsic to the uterine walls. It was probably a case of abdominal pregnancy, in which the ovum became attached to the posterior uterine wall, and derived muscular fibres from the locality. The fact that a continuity of muscular fibres from the normal uterus to the adventitious uterus might be ascertained upon microscopical examination, would prove nothing as to the nature of the pregnancy. Dr. Byford's case resembled that of Janvrin, in which the ovum lodged on the posterior uterine wall, and developed in this situation, involving the posterior wall in its sac. The specimen was worthy of more exact investigation, and should be placed in the hands of a competent pathological anatomist.

Dr. Sawyer said that abdominal pregnancy, with location of the ovum on the posterior uterine wall, is not at all improbable. He then referred to Bischoff's and Leopold's observations and experiments with relation to the "external wandering over of the egg." Beigel had ridiculed this idea. It was like a blind man introduced into a large empty room, with a thread in his hand, seeking to find and thread the eye of a needle located in some indefinite quarter of the room. Notwithstanding this sarcasm, the fact of the external wandering over of the egg was a matter of positive knowledge. The egg may pass from one ovary to the opposite Fallopian tube, through the abdominal cavity. He thought the specimen exhibited was one of abdominal pregnancy.

Dr. Dudley thought the fact of the external wandering over of the egg was not disputed at the present time. Playfair, in his treatise on *Midwifery*, gave a clear exposition of the subject.

Dr. Earle said that the fact of external wandering over of the egg was fully recognized twelve years ago.

Dr. Sawyer said the ovum in abdominal pregnancy might be attached to the posterior wall of the uterus, the mesentery, under surface of the liver, or to other viscera.

Dr. Nelson made the remark that in both of the cases cited by Dr. Byford, *deciduæ* had been cast off by the *uteri*.

Dr. Jackson said that Fränkel was of the opinion that the formation and extrusion of a decidua was a constant occurrence in extrauterine pregnancy. It was pathognomonic of the condition.

Dr. W. H. Byford was not surprised that certain members did not agree with him in his diagnosis. He thought that in the first case the fecundated ovum passed through the tube, but had found some diverticulum in the uterine cavity, and had passed into the posterior wall; had developed in this region, pushing the wall before it. Some of the reasons for this position were as follows: The muscular elements of the sac were directly continuous with the uterine muscle. He did not believe that such a muscular sac could develop adventitiously in the abdominal cavity. He had seen cases of abdominal pregnancy in which no muscular fibre could be detected in the sac. The head presentations, deep down in the pelvic cavity, in the direction of the resultant of the forces developed by uterine contractions, supported his view of the case. It is not necessary for the production of mural pregnancy that the tubes be involved. He thought there was much in the remarks of Dr. Nelson and Dr. Dudley. In cases

in which there was sufficient contractility, it was best to remove the placenta. Even under these circumstances, it was not absolutely necessary. There was no danger in allowing the placenta to remain. Finally, he was very positively of the belief that the two cases referred to in his paper were examples of mural pregnancy. The peritoneum was a boundary line between mural and abdominal or peritoneal pregnancies.

Dr. Sawyer asked the question, Is the peritoneum a boundary line of importance in the macroscopical or microscopical differential diagnosis between abdominal and mural pregnancies?

Dr. Jaggard, in reply, said that the peritoneum was no barrier. What was the peritoneum? Dr. Etheridge, in an article on "Chronic Adhesive Perimetritis," published in a recent number of the *Chicago Medical Journal and Examiner*, had ably sketched the anatomy of this membrane. It was developed out of connective tissue, according to Rindfleisch and other distinguished anatomists. It offered absolutely no barrier to the attachment of the ovum to the posterior uterine wall, and its development in this situation, with the derivation of muscular elements from the normal uterus.

On motion, Drs. Byford, Merriman, and Jaggard were appointed a committee to select a competent pathological anatomist, who did not belong to the Society, to examine the specimen and report at the next meeting.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, Dec. 23, 1884.

The President, Robert F. Weir, M.D., in the Chair.

Dr. W. T. Bull presented a patient showing the result of

EXCISION OF THE CONDYLE AND NECK OF INFERIOR MAXILLA FOR ANKYLOSIS.

A boy of 14 had been perfectly well until four years ago, when he had an attack of otitis media of the right ear lasting about six months. During this time it was first noticed that he could not fully open his mouth, and this difficulty increased until about three years ago, at which time Dr. Bull began treatment, various apparatus being used forcibly to open the mouth but with only temporary improvement under ether. Twice the adhesions have been ruptured, and stretching by means of gags and plugs kept up for several weeks. On ceasing treatment the stiffness increased. The treatment was very painful.

On admission to the New York Hospital, Oct. 22, 1884, the boy was well nourished and robust in appearance. The jaws could be depressed only so far as to show an interval of a quarter inch between the middle incisors. The left temporo-maxillary articulation appeared normal. The right was the seat of thickening and induration of the tissues overlying it. These formed a swelling the size of an almond, which was not tender.

Oct. 23, 1884, the operation was performed. An incision one inch and a half long was made just below and parallel with the right zygomatic arch. A second vertical incision three-quarters of an inch long was made downward from the first at its posterior third. These were carried down until the condyle and eminentia articularis were exposed. The condyle was thickened, and the joint ossified, at least the only indication of its existence was a thin layer of cartilage a quarter inch long. The periosteum was pushed back, and the condyle and neck removed with chisel, gouge, and roughened forceps. This was a tedious procedure, owing to the depth and narrowness of the wound. The jaw was then forcibly depressed with a gag, rupturing some adhesions in the soft parts, and its motions were perfect. The wound was irrigated with 1 to 1000 solution of bichloride of mercury, and closed with catgut sutures save at the lower limit, where a small bone drain was inserted. A temporary dressing of bichloride gauze was firmly applied.

24th.—A.M., 99°. A dressing of iodoform gauze next the wound, over this peat and cotton, was applied. P.M., temperature 99.8°.

29th.—Pulse and temperature normal since last note. Dressing removed. Union complete save at site of tube, where a small ulcer remains. Tube had been almost wholly absorbed. Patient has no pain and opens his mouth freely, eating regular ward diet.

Nov. 5.—An ulcer size of split pea remains. Patient opens jaw so that middle incisors are one and one-sixteenth inch apart. No pain.

Dec. 23.—There is the same freedom of motion as before noted. The cicatrix is represented by a depression vertical in direction, of one-half inch in length.

COMPOUND FRACTURE OF INNOMINATE BONE; OPENING HIP-JOINT; RECOVERY WITH PERFECT USE OF LIMB.

Dr. W. T. Bull also presented a patient with this history.

Three years ago this man, a laborer, thirty years of age, was admitted to the Chambers Street Hospital half an hour after having fallen through a hatchway into the hold of a ship, a distance of twenty feet. He struck with right side against a pair of ice-tongs, the points of which made a wound below and behind the anterior superior spine of the ilium. The finger introduced into this found the muscles lacerated, the bone behind and below the anterior superior spine comminuted, and a fissure extending, it was thought, into the acetabulum, the capsule of the hip-joint was torn close to the acetabulum, and the cartilaginous head of the femur could be felt. There was profound shock. A few hours later the wound was enlarged, and several loose pieces of bone removed. They were all fragments of the outer surface of the ilium, the largest was three inches long by one and a quarter inch broad.

The wound was thoroughly irrigated with a five per cent. solution of carbolic acid, two large drainage-tubes were left in the wound, which was left open, and two other tubes were inserted through counter-openings, behind the trochanter and near the tuberosity of the ischium, one of the tubes leading to the site of the opening in the capsule. Compresses of two and a half per cent. carbolic acid were put over the hip, a weight and pulley extension applied—the tubes washed through four times a day with two and a half per cent.—and appropriate general treatment ordered.

From the third to the seventh day there was high traumatic fever, temperature 102½° at night, with delirium, diarrhœa, and prostration. The irrigations were made every two or three hours, and the discharge was

abundant but not decomposed. After this improvement was slow but steady, and without other complications than the formation of one or two pockets, which gave rise temporarily to fever. The extension was kept up for four weeks. The tubes were shortened from time to time, and the irrigations were made much less frequently. The man walked on crutches at the end of the third month, with considerable stiffness at the hip, and the wound was reduced to one sinus, through which several fragments of bone came away subsequently. At the end of the fourth month he had quite regained his strength, and could walk with but little stiffness. He resumed work after the end of six months—but the sinus did not close till several weeks later. He had had no further trouble from the injury, and thinks the functions of the right leg perfect. It is now three years since the injury, and I find the limb half an inch smaller in circumference at the upper part of the thigh, and one-quarter inch smaller at the lower third, than the left. The motions of the joint are free, except that of external rotation, but the hindrance is not sufficient to attract his attention. There is flattening of the soft parts between the anterior spine and the trochanter, and the brim of the pelvis for four or five inches behind the anterior superior spine is irregular in outline. The cicatrices are soft.

DR. GEORGE A. PETERS then read a paper entitled

CASES OF EXCISION OF SUPERIOR MAXILLA, WITH REMARKS.

(See next number of THE MEDICAL NEWS.)

DR. H. B. SANDS said that the main points of the paper were scarcely debatable, as the Society would doubtless endorse most of the opinions expressed by Dr. Peters. But, if he had not misunderstood the author of the paper, he had recommended

THE ADMINISTRATION OF ETHER BY THE RECTUM

as a safe and useful method. Dr. Sands had had no experience in this mode of producing anæsthesia, which had not impressed him favorably.

But, as many of the members of the Society had had such experience, he would like to inquire whether their verdict would sustain the position taken by Dr. Peters. Judging from what he had learned concerning etherization by the rectum, Dr. Sands had concluded that it was far from being a desirable procedure, as it was attended with risks which are difficult to avoid, and almost impossible to estimate. He had the privilege of witnessing the operation described in the paper; and, being only a spectator, he was perhaps able to observe better than those who were engaged in performing the operation the effect of the anæsthetic. It seemed to him that the ether was but little under the control of the administrator, and that, in spite of the precautions used, a very large accumulation took place in the intestine, with the effect of producing cyanosis and very deep anæsthesia for a period which made a bystander feel anxious with regard to the result.

Dr. Sands would hesitate from what he had observed in this case, even in operations of the kind mentioned in the paper, to adopt this method as a substitute for inhalation in the ordinary way. His own practice, when employing anæsthetics in the operation for excision of the superior maxilla, had usually been to avoid inducing profound insensibility in the later steps of the operation. By adopting this precaution, by operating without undue delay, and by causing the head to be inclined forward whenever hemorrhage was copious, he had always been able to prevent the entry of blood into the air-passages, without the necessity of plugging the trachea. Patients treated in this manner sometimes showed signs of pain, especially when the larger nerves were divided; but afterward they had no recollection of having suffered during the operation. Dr. Sands believed that in all surgical procedures accompanied with the risk of escape of blood into the larynx, deep anæsthesia should be avoided. Regarding the general administration of ether by the rectum as a substitute for the usual method by inhalation, he would like to know whether the advantages were not outweighed by the risks.

DR. W. T. BULL said that he had considerable experience with etherization by the rectum, the results of which he had already published. He had administered ether in this manner in seventeen cases, and had reached the conclusion that the method should not be practised, because in a large proportion of those cases the reaction which followed, on the part of the intestinal tract, was very considerable. In some cases there was diarrhœa, with bloody passages, and in others ordinary serous diarrhœa, and the diarrhœal discharges seemed to occur without very much reference to the apparent good general condition of the patient. In one case the diarrhœa continued for two or three days after the operation. Judging from his own experience, he was unable to call etherization by the rectum a safe procedure, and this conclusion had been confirmed by the occurrence of deaths, in different hospitals, from ether administered in this way, and when there was nothing in the nature of the operation which would have imperilled the life of the patient. In the operation in question, he should prefer to trust to the method mentioned by Dr. Sands, rather than resort to etherization by the rectum.

DR. L. A. STIMSON remarked that he had already presented to the Society an instrument devised for continuing etherization during the operation described by the author of the paper. The instrument consisted of a large tube, about the size of a No. 40 urethral catheter, surrounded at one end by a large sponge with a rubber coating, which, when passed into the pharynx, prevented the flow of blood in that direction while the patient breathed through the tube. He had successfully used this apparatus in two cases.

DR. PETERS said that his feeling concerning etherization by the rectum was such as had been stated by Dr. Sands, unless the method could be surrounded by safeguards in the administration which would deprive it somewhat of its dangerous element. The results in the two operations described in the paper, performed upon a single patient, were eminently satisfactory. The patient was profoundly anæsthetized, and the anæsthesia continued for some time, but he came out from under the influence of ether with less subsequent annoyance than usually follows the administration of this anæsthetic. The patient himself was so much pleased with the mode of administration that at the second operation he requested that the same method be employed as was adopted at the first operation, a point which, of course, went only for what it was worth. Like the administration of ether by any method, it was

important to conduct the procedure very carefully. From the experience with these cases, Dr. Peters stated that he should give this method further trial.

DR. BRIDDON had employed Nussbaum's method with much more pleasant results than any other he had employed. The method consists, first, in the administration of a full dose of morphine hypodermically, ten or fifteen minutes afterwards administering the anæsthetic, then making an incision into the trachea or larynx and introducing a tube with a funnel-shaped extremity, over the end of which is secured a piece of flannel, upon which chloroform can be dropped, using it in preference to ether. In the mean time the fauces are packed to prevent blood from entering the air-passages. The quantity of chloroform sufficient to maintain anæsthesia under these circumstances is exceedingly small; usually only a few drops being required. He had seen anæsthesia produced by the rectum in a number of cases by his friends, and he thought their experience was similar to that related by Dr. Bull, and that none of them would adopt the method at the present time.

THE PRESIDENT remarked that his own experience with rectal etherization was checked early by an unfortunate case in which death resulted. It was true that in that particular case, which had been published, some errors in the mode of administration were made. Since then he had administered ether in this manner four times; in two cases the method worked satisfactorily, and in the other two cases there was some diarrhœa with dysenteric stools. He had reached substantially the conclusions already expressed by other members, and it was, to his mind, a method attended with considerable risk; too great a risk to be lightly resorted to. He thought that the opinions already expressed had been confirmed by reports from Philadelphia and Boston, and also in the English journals. The method of managing the anæsthesia mentioned by Dr. Sands had suited him best in the operation of extirpation of the upper jaw.

DR. L. A. STIMSON presented a

SPECIMEN FROM A CASE OF OVARIOTOMY,

with the following history: A patient, 43 years of age, in good health, a widow, the mother of one son eighteen years of age, first noticed a tumor in the left iliac fossa five years ago. It steadily increased in size, and she finally sought relief, by operation, from the distress occasioned by the weight and pressure of the tumor. There had been no disturbance of the menstrual function. Dr. Stimson operated on the 17th of December, by making an incision a little to the left of the median line, midway between the umbilicus and pubes. On account of the thickness of the abdominal parietes the incision ultimately reached four inches in length. When the peritoneum was exposed it was divided with scissors to the extent of about one inch. A trocar was then inserted into the tumor; two and a half gallons of rather thick, opaque, brownish-gray liquid were withdrawn. The tumor was grasped with the volsella forceps, drawn out through the incision, and it was then ascertained that it had no pedicle, but had developed between the walls of the broad ligament, and was continuous with the left side of the uterus. The uterus was drawn up into the opening, an incision made into the posterior wall of the sac, and an attempt made to enucleate the sac. After this had been carried far enough to make it probable that enucleation could be completed, a stout catgut ligature was placed, by transfixion, about that portion of the mass which corresponded to the left Fallopian tube, and the upper portion of the sac was then cut away; enucleation of the remainder was rapidly completed. The portion of the sac adjoining the uterus was trimmed down and united along the sides of the uterus with a continuous catgut suture; the raw surface of the uterus thus covered in was sprinkled with iodoform. The walls of the pouch left after enucleation were drawn up into the abdominal wound and fixed with sutures to the skin. A rubber drainage-tube was passed into Douglas's pouch, a bone drain into the lower angle of the wound, and a second rubber drain into the pouch. The antiseptic precautions observed were purification of the hands and instruments, bichloride irrigations during the operation, and the use of sponges dipped in a warm carbolic solution after the peritoneal cavity had been opened. Two of the drainage-tubes have been removed, the bone one on the second and the first rubber one on the third day; the drain which entered the pouch of enucleation is still retained, although there is but scant discharge from it. Since the operation the patient has done perfectly well. The sac of the tumor had a rather thick wall, with a rough and granular inner surface. In the portion of the sac cut off, the line of incision passed through a number of small cysts, which occupied the wall of the sac and which contained a brown and rather viscid liquid.

In response to a question asked by the President, DR. STIMSON said he made the incision a little to the left of the median line for two reasons: first, he wished the parietal wound to include the muscular layer; and, second, because the tumor was situated upon the left side, and a lateral incision, he thought, would somewhat facilitate the operation upon the pedicle.

DR. BRIDDON presented a specimen of

DISLOCATION OF THE THUMB FORWARD,

which occurred nineteen years before the death of the patient. It was referred to a committee, consisting of Drs. Briddon and Stimson, for examination and subsequent report.

LAPARO-HYSTERECTOMY FOR UTERINE FIBROIDS.

DR. WEIR showed a specimen of uterine mural fibroids weighing eleven and a half pounds, which he removed by abdominal section at the New York Hospital, November 21, 1884, from a single woman, 45 years of age, who was much exsanguinated by hemorrhage of five years' duration. The operation was conducted in a room filled with carbolic spray, though none was directed upon the seat of operation. The incision required was nearly eight inches long, and just permitted the emergence of the tumor, which was irregular in shape; being, in fact, trilobed. The broad ligament, with the ovaries, was tied off by silken ligature, and then divided down to the neck of the uterus. Thornton's clamp or écraseur was temporarily passed around the mass to make a groove for the elastic ligature, which was then tied tightly and the parts above removed. About two inches of the cervix were left. This stump was very movable, and could easily be applied to the

lower angle of the wound. It was secured there by a long needle, which traversed it and rested with its free ends on each side of the abdominal wound. The parietal peritoneum was sewn about the pedicle; first to the skin, subsequently to the peritoneum of the pedicle, so as to shut it off from the general peritoneal cavity. The remaining portion of the wound was closed as usual, the peritoneal edges being sewn, in addition, by a continuous catgut suture. The pedicle was dusted with iodoform, and peat bags applied to keep the parts as dry as possible. The patient did well for three days, when elevation of the temperature coming on, 103° F., with distention of the upper part of the abdomen, a rubber coil was applied to the belly. The next day, repeated bloody evacuations from the bowels took place, which continued with normal temperature until November 27, when she died. The autopsy showed no inflammatory action in the abdominal cavity, nor in the abdominal walls. Micrococci were found in the kidneys, which were in a condition of chronic interstitial nephritis. The quantity of urine passed subsequent to the operation was satisfactory. In addition to the uterus removed, specimens showing the line of union of the wound and the condition of the stump were exhibited.

Dr. Hutchison inquired concerning the usual behavior of elastic ligatures when left in the abdominal cavity.

Dr. Lange said it seemed that in most cases the rubber ligatures became encysted when left in the abdominal cavity, and gave no subsequent trouble. In his last case, however, about eight weeks after the operation the patient began to have a discharge, and the ligature with the stump of the uterus came away through the vagina. At that time the patient had passed from under his observation. Subsequently he saw the patient; and she was in a very comfortable condition, although there was still some discharge from the vagina, but he was unable to detect the opening through which the ligature and the stump of the uterus had escaped. It seemed to him that they must have passed through the cervical canal. He might also mention that the ligature was applied very deep, immediately above the fornix of the vagina, and perhaps this immediate proximity to the vagina had something to do with the discharge of the ligature through the cervical canal.

Dr. W. T. Bull had had a similar experience with regard to the silk ligature after removal of the uterus, with the ovaries, for a large subperitoneal uterine fibroid. Six months after the operation the patient returned, and said that a discharge from the vagina had persisted since about two months after the operation, and on making a vaginal examination he saw a piece of silk, hanging from the os, which he seized and withdrew, and found to be the entire ligature.

In cases in which the uterus is made the pedicle, the fact of the liability of the escape of the ligature and the stump through the vagina, had been used as an argument for the external treatment of the stump; at all events, it was one of the features of the intraperitoneal treatment which was undesirable.

Dr. Lange remarked that it was difficult to see how one could secure a deep situated pedicle and treat the stump with the ligature through an external opening.

Dr. Briddon thought that no definite rule could be established, but that each case should be decided by itself, and chiefly by the length of the pedicle. He thought that the manner of escape was easily explained by the results of experiments which had already been reported in Sir Spencer Wells's book, namely, that the sutures shut off entrance to the peritoneal cavity, adhesions between the peritoneal surfaces occurred within a few hours, and if ulceration went on, the more direct way of escape was into the vaginal cavity.

Dr. W. S. Halsted exhibited

A NEW NEEDLE HOLDER,

for holding needles flattened from side to side instead of antero-posteriorly. The especial advantages which it possessed were, that it could be taken apart readily and cleaned, and it did not allow the needle to rotate and slip.

CORRESPONDENCE.

INTERNAL MEDICINE IN THE VIENNA HOSPITALS.

To the Editor of The Medical News.

Sir: Certain features render Vienna, of all places, perhaps, the most attractive to physicians seeking experience and information in the various branches of medical science. They are, namely:

1. That into or about one great hospital is gathered by far the larger portion of the vast clinical material of the city.

2. That the patients here are thoroughly utilized for purposes of instruction, suffering, meanwhile, no detriment themselves thereby.

3. That the instruction given is of the very best practical kind.

That this is no overestimate of the advantages to be found here is proved by the presence of a very large number of foreign physicians from almost every land. Of these, very many are subjects of the South American States, Great Britain, and Germany; but by far the greater portion comes from the United States of America, which country contributes probably over one hundred physicians, including about ten women.

The method of instruction is by clinical and didactic lectures given by the many professors, and by the University courses and private courses given by them, and the very numerous "docents." The number of these courses advertised on the bulletin boards of the hospital is indeed so great as to be absolutely bewildering to a new-comer.

The University year is divided into two terms or "semesters," in which time are held the regular lectures, clinics, and courses; and, entirely independent of them, the private courses. During the holidays many of the latter still continue, so that plenty of instruction can be procured throughout the entire year. The duration of each private course is from four to six weeks. The University courses continue the entire term.

At 7 A.M. throughout the summer semester, and at 8 A.M. during the winter, begin the two clinical lectures on internal medicine by Professors Bamberger and Nothnagel. That of Nothnagel is the one more sought after by the foreign physicians.

The oftener one hears him the more does one admire

the distinguished clinician's evident mastery of his subject, and great ability as a lecturer.

The case having been brought before the class, one of the course students is called upon to examine it. He is requested first to interrogate the patient as to the nature of his disease. As the questions asked are frequently not much to the point, the lecturer supplements them by questions of his own, and then requests the assistant to read the clinical history. He next reiterates any matters of importance discovered from the history or by the questioning, and asks the examining student what different diseases could be indicated by the existing symptoms. Now, the direct examination of the case is commenced. No point is omitted. The student is asked to notice and describe the color of the face and mucous membranes; the condition of the pupils, of vision, and of hearing; the state of the sensorium; the condition of the glands of the neck, and the presence of any visible pulsation in the vessels there; the inclination of the clavicles; the shape of the thorax and abdomen, and all characteristics and peculiarities to be found there; the amount of bony, muscular, and adipose development; the position of the body, etc.

Nothnagel evidently lays great stress upon inspection, and it is often surprising what valuable points of diagnosis he develops by it. He next gives the contents of the thorax and abdomen a most thorough examination by means of the remaining physical methods. It is worthy of note that he uses a percussion hammer and plexímeter. (The same is true, by the way, of Frerichs, Guttmann, and others in Berlin.) The frequency of the respiration and of the pulse is always counted in the presence of the class, and the examining student required to describe the character of the latter. The temperature is very often measured in the lecture-room and the urine always examined there. In cases of suspected pleuritic effusion, the "puncture test," by means of the hypodermic syringe, is also conducted before the students. Nothnagel depends almost entirely upon the reaction with potassium ferrocyanide and acetic acid in testing for albuminuria, beliving it to be delicate, reliable, and undoubtedly more convenient than that with nitric acid and heat. The record of the temperature for several days before is announced, and the sputum, if existing, is exhibited, and the result of any previous search for tubercle bacilli reported.

Having finished the examination, he enters upon the diagnosis of the case. All possible diseases capable of giving rise to any of the prominent existing symptoms are taken into consideration, and are one by one excluded, until the final diagnosis is attained. The lecture has been meanwhile delivered largely *at* the examining student, and interspersed with numerous digressions into the realms of medical diagnosis, and with frequent questions asked of the student involving his knowledge of anatomy, physiology, materia medica, and chemistry; with all which he is presumably familiar, having usually already passed examinations in them. Unfortunately, however, the German students share the fallibility of other men, and sometimes return surprising answers. One of them recently made the reply that calomel was a vegetable. Another, that potassium iodide was the form in which iodine was usually used as a counter-irritant; and that the prominent symptom of cantharis poisoning consisted in muscular cramps. Another, that during sudden anæmia of the surface of the body the blood is collected in the heart.

The digressions already referred to form one of the most interesting and instructive features of Nothnagel's clinics. For example, while lecturing on pneumonia, he may give a complete review of the varieties of cough, with their diagnostic indications. Or he may sometimes speak at length of sputum, chill, urine, etc.

Next in order the lecturer talks of the prognosis, first asking the opinion of the examining student; and finally of the therapeutics, although comparatively little is said on the subject.

He speaks rapidly and with vivacity, and holds the full attention of the class, although he often spends from one to two hours over a case. He delivers his lectures in a chiefly systematic course, being enabled to do this by the large amount of clinical material at his command.

Bamberger calls upon two students for each case; one to examine the lung, the other the heart and abdominal organs. He sits while speaking, and seems to address himself principally to the *bed*, inasmuch as he scarcely ever glances at either the patient, the examining students, or the class. His voice is very low and quiet, and it is almost impossible for a foreigner to understand him, unless seated very near the front. His method is just as thorough as Nothnagel's, but perhaps not so well calculated to instruct. He reads to the class the entire recorded clinical history, with the physical signs as already found; then, stating at once the diagnosis, he discusses thoroughly the usual symptoms and course of the disease. A physical examination of the patient is then made by the students, who, while conducting it, are questioned by the professor as to its results. Bamberger next carefully investigates the case himself, and then considers the prognosis and therapeutics.

As further distinguishing his clinical methods from those of Nothnagel, can be noted that neither plexímeter nor percussion hammer are employed; that all normal or abnormal areas of percussion dulness are invariably mapped out on the body of the patient with the aniline pencil; that the femoral artery is always auscultcd in any case of suspected valvular disease of the heart; that the urine is examined for albumen by the heat and nitric acid reaction only; and, further, that whereas the symptoms and course of the disease *in general* are very thoroughly discussed, its differential diagnosis in the case before the class is not so clearly elucidated.

But what to the foreign physician is of far greater value than the lectures of the professors are the *private courses*, of which the favorite ones, on Internal Medicine, are those given by Drs. Toelg and Von Jaksch, the first assistants respectively of Bamberger and Nothnagel. The members of these courses have the opportunity of personally studying in the wards many most interesting cases. A patient is assigned to two physicians who carefully examine him, and form their own diagnosis of the disease. The assistant then thoroughly discusses the case, and approves or criticises the diagnosis. They endeavor to teach the newest and best methods of medical diagnosis, including also the examination of sputum for tubercle bacilli, of the blood for any microscopical changes in it, and of the urine for any chemical or microscopical alterations.

Toelg's method of demonstration is wonderfully clear;

that of Von Jaksch thoroughly scientific. With the former, the physician studies his own case only; with the latter, he has the opportunity of examining those belonging to the other members of the class, and of hearing the docent's discussion of them. As these courses are in great demand, and are limited to eight or ten men, it is often necessary to make application months in advance.

The hospital offers numerous other courses in this branch of medical science, some excellent; as, for example, those of Dr. Neusser, Dr. Heitler, and Prof. Schrötter. Schrötter was an assistant of Skoda, and, it is said, follows his methods of demonstration. He shows clearly how the sounds of percussion and auscultation can be produced artificially, and then exhibits cases to illustrate them.

Any one often in the wards for Internal Medicine will notice many interesting characteristics of diseases, and their treatment there. The first and most striking of these is the dreadful prevalence of tuberculosis. So common is it, indeed, that it goes by the name of "*Morbus Viennensis*" as frequently as by any other. The possibility of its causing or complicating other diseases must be always considered here. Primary pleurisy in the Vienna hospital is comparatively so rare that a case of it was recently exhibited as almost a curiosity. Unfortunately for the patient, the effusion obstinately resisted treatment, and soon evident signs of infiltration of the lung of the other side appeared, thus establishing the disease as probably in this case, too, a secondary affection. In the wards of both Bamberger and Nothnagel the finding of tubercle bacilli is considered proof positive of the existence of tuberculosis. Nothnagel institutes an investigation of the sputum in all suspected cases. He insists, however, that a single examination, in case no bacilli are found, shall not be considered decisive, but that it shall be repeated many times. If, after numerous examinations, none can be discovered, he maintains that the presence of tuberculosis is certainly exceedingly improbable. These conclusions are the result of the careful study of the sputum of hundreds of patients.

As common as is tuberculosis, almost so rare appears to be typhoid fever, of which comparatively few cases are to be found in the hospital. It was formerly as prevalent in Vienna as in other localities; but on the introduction, in 1873, of the present water supply, coming from the Styrian Alps, a notable decrease in the frequency of the disease took place.

Noticeable also is the largely expectant plan of treatment followed in many diseases. Cases of pleurisy and pneumonia receive usually a purely symptomatic treatment. In impending heart-failure, in the latter disorder, dependence is placed on large doses of alcoholic stimulants. The employment of diuretics or purgatives in pleuritic effusion is almost entirely discarded, and the fluid either trusted to nature, or, when necessary, aspirated. Acute Bright's disease and typhoid fever are also treated purely expectantly. Cold applications are made in those cases of inflammation in which hot would generally be employed in America. The hypodermic syringe is very freely used as a means of diagnosis of the presence and nature of fluid contained in the pleural or abdominal cavity.

Neither cod-liver oil nor iron is given in phthisis or other diseases when there is accompanying fever. The temperature is often recorded every two hours in cases in which it is likely to rise above the normal. A daily record of the quantity of urine passed and its specific gravity, and of the number and character of the stools, is noted on the chart above each bed. The cold bath treatment of fever is not much employed; but as an antipyretic, quinine is used in the wards of Bamberger, and in those of Nothnagel is at present given *thallin*, a most valuable agent, whose properties were recently described by Von Jaksch, before the Wiener K. K. Gesellschaft für Aerzte. In diabetes mellitus a strictly non-amylaceous diet is not adhered to, and no reliance is placed on medication. If the patient can be sent to Carlsbad, strong hopes are entertained of a cure, or of great amelioration of all the symptoms. Catarrhal icterus is generally treated with Carlsbad water. The doses of morphia are usually quite small, about one-tenth of a grain being the amount given hypodermically. The prognosis of the disease is always spoken in Latin in the presence of the patient, and death called "*Exodus lethalis.*" Latin, indeed, is very commonly used whenever it is desired that the patient be kept in ignorance of the remarks made.

Closely connected in many branches with the subject in hand, is that of the diseases of children. These, although well taught, do not offer so many opportunities for study as could be desired. The two principal clinics are those held by Prof. Monti in the Polyclinic, and by Prof. Wiederhofer in the St. Ann's Children's Hospital, both institutions situated quite near the general hospital. Monti sits at a table on which the child is placed, and around which the class gather. After eliciting the symptoms, by a careful questioning of the mother, he examines the patient, and then discusses fully the nature and differential diagnosis of the disease, and with particular care the therapeutics. The prescriptions to be employed are written upon a black-board provided for the purpose. The child is then taken about among the students for examination by them. The latter portion of the hour is devoted to a systematic lecture, continued from day to day, upon some selected branch of children's diseases. Much can be learned at this clinic, although no great opportunity is given for personal examination of the cases, as the course is largely attended, and but few patients exhibited daily.

Wiederhofer's clinic is conducted very similarly, except that no systematic lecture is delivered. It has the advantage that many house-patients are shown, as well as those from the ambulatorium. The lecturer states the diagnosis as soon as the child is brought in, and says but little on the subject. He then examines the case, and discusses the symptoms and treatment in an unsystematic and informal, but very interesting manner. An opportunity is given for personal examination of the patient. After the lecture, the class accompany the professor in his visit through the wards. The privilege of attending the very large ambulatorium of the hospital can often be obtained. Here frequently as many as one hundred children can be seen in the course of the morning. Wiederhofer's assistant, Dr. Frühwald, often gives excellent courses. Very good courses are also held by Dr. Fürth in the Polyclinic, and by others elsewhere.

It is, of course, of the greatest practical benefit to a

physician to be able to compare the diagnosis made during the life of the patient with the actual condition of the organs as seen on the post-mortem table. This can be done here to wonderful advantage, and microscopic pathological anatomy studied with great profit.

There is in the general hospital a death rate of about three thousand patients yearly, and on all of these the pathologists have the right to make post-mortem examinations. In point of fact, from eighteen hundred to two thousand such examinations are made, beside the autopsies of the criminal, accident, and similar cases of the city, which are also conducted in the hospital. Autopsies can be witnessed during almost the entire morning, and in the afternoon an excellent private course, limited to ten or twelve members, on the making of post-mortem examinations and the recognition of fresh pathological specimens, is held by Dr. Zeman, the assistant to Kundrat, the professor of pathology. In this there is such a wealth of material at hand, that the question is not what can be found interesting to the class, but what "will keep until to morrow."

During the first half of the course, Zeman exhibits and explains pathological specimens, and usually during the latter portion the members of the class make their own diagnosis of specimens given them. Throughout the whole course they have opportunities to perform autopsies under the direction of the docent. His method of making autopsies is rapid, complete, and very systematic, and the student's eyes thoroughly trained to notice even slight pathological changes. Those desiring it can attend systematic lectures on pathological anatomy by Prof. Kundrat, and on experimental pathology by Prof. Stricker. There is also a large museum of alcoholic specimens.

Good opportunities are offered for the study of pathological histology, although this is not so well taught as in Heidelberg or Strassburg. At the Rudolph's Hospital, which is unfortunately a long distance from the general hospital, Dr. Weichselbaum gives excellent courses on both macroscopic and microscopic pathological anatomy.

J. P. CROZER GRIFFITH, M.D.

VIENNA, Dec. 24, 1884.

COCAINE IN DYSMENORRHŒA.

To the Editor of THE MEDICAL NEWS.

SIR: Having employed the new anæsthetic, cocaine, with the happiest results, in a case of dysmenorrhœa, I thought it might be of interest to publish the facts.

My patient has suffered for years from painful menstruation, accompanying a retroflexion of the uterus, complicated with adhesions. The deformity of the uterus has been rectified by treatment, but the pain during the menstrual period is still as agonizing as ever. The most acute and intolerable anguish is felt in the left inguinal region, and is accompanied by a wind colic that causes the sufferer to writhe in agony. Nausea and vomiting add to her distress, and she seems at times ready to go out of her mind with suffering.

While still hoping to effect a permanent cure of this condition by appropriate treatment, temporary relief by the administration of morphia is all that I have hitherto been able to afford her; at the same time, that drug produces such disagreeable effects, that the remedy is only not quite so bad as the disease. It excites the nervous system, banishing sleep, it adds to the nausea, increases the prostration, destroys the appetite, and fails to keep off the wind colic. But on the last occasion, instead of morphia, I used cocaine, injecting subcutaneously over the left ovary, at first three, increased afterwards to five minims of a four per cent. solution. Almost immediately after each injection the pain in the inguinal region ceased to be felt, the nausea and wind colic were relieved, and, instead of nervous excitement and wakefulness, a soothing effect inclining to sleep was experienced. Five minims of a four per cent. solution were sufficient to afford complete relief for five or six hours, and comparative immunity for a much longer period.

While, however, the drug acted thus admirably, both locally and generally, it had no effect, apparently, on the bearing-down pains, and pain in the back, but only upon the local pain in the neighborhood of the spot where it was injected. It was also noticed, that, while it relieved the nausea and vomiting of a reflex origin, it sometimes caused slight nausea itself, but this was only temporary. No other unpleasant effect was experienced, if we except a slightly bitter taste imparted to the tongue.

If cocaine can thus be made to supersede morphia in such cases, it will certainly prove an inestimable boon to many an unfortunate sufferer. And if it is able to relieve that excruciating intestinal pain usually called wind colic, which in so many cases is sure to follow the slightest surgical interference with the uterus, this of itself will be no mean trophy added to its many wonderful triumphs over human suffering.

JOHN FORREST, M.D.

CHARLESTON, S. C.

NEW INVENTIONS.

A NEW EVACUATOR

FOR THE REMOVAL OF CALCULOUS DÉBRIS FROM THE BLADDER AFTER LITHOTRITY.[1]

BY H. O. WALKER, M.D.,

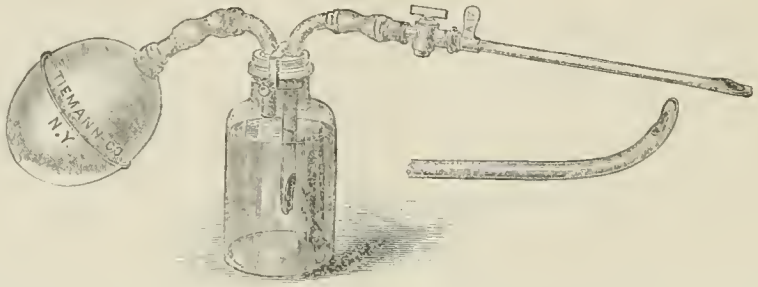
PROFESSOR OF GENITO-URINARY DISEASES, ORTHOPÆDIC SURGERY AND CLINICAL SURGERY, IN THE DETROIT MEDICAL COLLEGE, AND SURGEON TO HARPER HOSPITAL, DETROIT, MICH., ETC.

THE instrument consists of a six-ounce wide-mouthed glass bottle, fitted with a rubber stopper having two openings through it for the introduction of two metal tubes, one short, extending down about half an inch below the stopper, and the other long, extending to within one inch of the bottom of the bottle, with an oval (side) opening. These are held in place by a steel bar or flange over the stopper, and fastened by a screw.

The metal tubes are curved at their upper extremities, both having for a medium of connection a short piece of rubber tubing. To the short one is attached a rubber bulb, and to the long one the evacuating-tube, with stopcock and bayonet connections. The evacuating-tubes vary in size, with either curved or straight extremity. No. 26 F. is the one best adapted to general use, and less liable to do injury to the deep urethra. When in use the bottle is to be filled with warm anti-

[1] Exhibited before the Michigan State Medical Society, June 11, 1884.

septic water just to clear the opening of the short tube. After the introduction of the evacuating-tube into the bladder, it will be well, before making the connection with the long tube, to exclude the air. This can be done by forcing water into it by a slight pressure upon the bulb, and then closing the stopcock. Everything being in readiness, the connection is made and the stopcock opened and gentle pressure made upon the bulb, so as to force out from the bottle about an ounce and a half of water, when by a sudden relief of pressure



upon the bulb a return current takes place bringing with it broken calculus. The repetition of this manœuvre is kept up until the operation is completed. Experiments which I have made with it, both in a glass bottle and a soft rubber bag, satisfy me as to the ease and rapidity of its action. Another important feature of its working is that no fragments pass back into the bladder after they have once fallen into the bottle. It is entirely under the control of the operator, and does not require an assistant to work the bulb.

I am indebted to Dr. D. C. Wade, of Holly, Mich., for suggestions, and to Mr. Stohlmann, of Tiemann & Co., New York, for the care which he has manifested in the manufacture of the instrument.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

Dr. Rudolph Tauszky, who has figured in the courts for some time past as an "expert" in insanity cases, tried to kill his wife, and afterwards fired a ball at his own head, which he wounded slightly. He is now at the Presbyterian Hospital, and the "penny dreadfuls" are advancing all sorts of theories. No one, however, disputes the fact that he is insane.

The Dispensary advantages in this city are so extensive that the poorer and sometimes even the middle classes are enabled to get good medical and surgical advice without pay. Since the two institutions for advanced medical learning have been established, there is not enough clinical material "to go around." It is now no common matter to find "interesting cases" hiring themselves out at rentals ranging anywhere from twenty-five cents to one or two dollars per lecture, and if this thing goes on the possessor of a well-marked case —say, for example, of lupus—may regard his "face as his fortune."

Civil Service Reform.—So far as the workings of Civil Service Reform are concerned in this city, there might be an improvement. It is to be regretted that so much red tape entangles them, and that applicants must wait so long before coming up for examination. The fault is not with the medical examiners, but with the other officials.

The Brooklyn Board of Health has recently done good work and every precaution has been taken by Dr. Raymond and his assistants to guard against the approach of cholera.

Hermaphrodite Show.—There is an hermaphrodite who exhibits herself (?) in a down-town street, her chief patrons being brokers and fast men about town. She has been facetiously named "Madame Duplex," and is coining money as the result of the prurient curiosity of her many visitors.

The English Cholera Commission.—Doctors Klein and Gibbes have completed their investigations, and have submitted a short preliminary report. They state that Koch's comma-bacilli are not peculiar to cholera, but occur in other intestinal diseases; that these bacilli do not behave in any way differently from other putrefactive organisms; and that inoculations of animals with recent and old cultivations of comma-bacilli, as well as with cholera dejecta, produce no effect.—*Med. Times and Gazette*, December 13, 1884.

Cholecystotomy.—We learn that Dr. Charles J. Parkes performed cholecystotomy, on January 19th, on a female, aged 35, who suffered from enlargement of an uncertain nature in the region of the gall-bladder, which, owing to the fact that she had passed gall-stones, led to the belief that it was due to impacted gall-stones. An exploratory incision was make under strict antiseptic precautions, the gall-bladder was penetrated, emptied of its contents, and stitched to the edges of the wound. No gall-stones were found, but the bladder was distended with clear mucus. The day following the operation, the case was doing well.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 30, 1884, TO JANUARY 5, 1885.

Girard, A. C., *Captain and Assistant Surgeon.*—Ordered from Department of Missouri to Department of the East.—*S. O. 304, A. G. O.*, December 29, 1884.

Appel, A. H., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, to take effect on or about January 7, 1885 (Madison Barracks, New York).—*S. O. 268, Department of the East*, December 31, 1884.

Ewing, Charles B., *First Lieutenant and Assistant Surgeon* (Fort Stanton, New Mexico).—Granted leave of absence for two months.—*S. O. 304, A. G. O.*, December 29, 1884.

VOL. XLVI. SATURDAY, JANUARY 17, 1885. NO. 3.

ORIGINAL LECTURES.

THE METHODS TO BE PURSUED IN THE EXAMINATION OF PATIENTS SUFFERING WITH ABDOMINAL GROWTHS.

A Clinical Lecture delivered at the Jefferson Medical College Hospital.

BY J. EWING MEARS, M.D.,

LECTURER ON GYNECOLOGY IN THE JEFFERSON MEDICAL COLLEGE.

(Reported by W. H. Morrison, M.D.)

GENTLEMEN: The presence of this patient to-day affords me the opportunity of speaking to you with regard to the methods to be pursued in the examination of patients suffering from abdominal growths. Having first obtained the history, the patient is to be prepared for the examination by adopting a dress which would be suitable to be worn in bed. This implies the removal of all constriction from the waist and a perfect freedom of exposure of the surface of the abdomen. Having the patient prepared in this way and placed on her back on the table, the first step in the examination is inspection.

Inspection: The surface of the abdomen is inspected in order to ascertain whether it is uniform in shape. Its contour is observed and any enlargements or projections are to be noted. In practising inspection we should note not only any irregularities of the surface, but also the condition of the integument and any marks which may be found in the integument. For instance, your attention is called to a line which frequently exists between the umbilicus and the pubes. Formerly this line, which has a brownish color, was regarded as diagnostic of pregnancy, it being usually found, or almost as a rule, in women who are pregnant. This line is also observed in the patient before you and I have seen it in a number of cases of abdominal tumors. It is, therefore, not pathognomonic of pregnancy, but it also exists in other cases of enlargement of the abdomen. This line is due to a pigmentary deposit, and, so far as I can recollect, I have never seen any satisfactory explanation why it should exist. In a recent case of ovariotomy not only did this line exist prominently between the umbilicus and the pubes, but brownish spots were also found on different parts of the body, face, chest, and right side of the surface of the abdomen and on the lower extremities. In this case the patient stated that the brown line and spots appeared after the development of the growth. Further, after pregnancy to full term has occurred, the surface of the abdomen may be marked by cicatrices, which indicate undue stretching of the integument. I call attention to this point, since it has happened in cases which have been presented at the clinic, that pregnancy has occurred in unmarried females and the history of the case has been entirely opposed to any such condition.

Having learned all that we can from inspection, the next step in the examination is palpation.

Palpation: By palpation we mean pressure with one, two, or three fingers upon the abdomen, carrying this, if necessary, to some depth. In order to facilitate this manipulation, it is desirable that the patient should be directed to inspire and then make a forcible expiration. By this means the diaphragm is drawn up and the walls of the abdomen are relaxed and deep palpation can then be made. By means of palpation we ascertain whether the cavity of the abdomen or the cavity of the pelvis is occupied by a growth, and, further, whether the growth is hard, soft, or elastic.

Percussion: The next step is to percuss the abdomen. Percussion is familiar to you all as one of the methods employed in the examination of the thoracic cavity. Beginning in the median line, we percuss downward from the ensiform cartilage to the umbilicus and from the umbilicus to the pubes. The patient is then turned on her left side and percussion made over the right side of the abdomen and the right lumbar region. She is afterwards turned on the right side and the left side percussed in a similar way. Percussion gives us an idea in regard to the character of any growth in the cavity of the abdomen. The percussion note obtained over the intestine is resonant, or even more than resonant, tympanitic in character. Over a solid tumor the percussion note would be dull or flat. Over a cyst containing fluid it would also be flat or dull. By percussion, therefore, we determine whether the abdominal cavity contains anything more than the intestines, which emit a resonant or tympanitic sound on percussion, and the extent to which the growth occupies the cavity.

Auscultation: Auscultation is also to be employed in the examination of abdominal growths. In carrying out this procedure it is necessary to apply the ear to different parts of the surface of the abdomen. If there is any reason to suspect pregnancy, the ear should be first applied over the left side of the abdomen, midway between the umbilicus and the middle of Poupart's ligament. At this point the fœtal heart sounds can usually be heard, if the embryo occupies what is considered its normal position, that is, with the vertex to the left. Auscultation also enables us to determine whether or not the swelling which is present is due to to aneurism, for by this means the presence of the aneurismal bruit can be determined.

The effort to elicit *fluctuation* is the next step in the examination. By this is meant the production of a wave through the mass of fluid when the walls of the abdomen are struck or percussed. If one hand is placed on one side of the abdomen, and the other side is percussed with one or two fingers of the other hand, the movement of the fluid is felt distinctly. This wave differs much in amplitude according to the density of the fluid and also according to the character of the cyst in which it may be contained. If the fluid is thin and limpid, the wave is long; if the fluid is very dense and viscid, the

wave is short. The ability to determine these differences is acquired largely by experience. I simply give you here general statements in regard to the differences in the fluctuation wave in fluids of different density. Fluctuation also enables us to a certain extent to determine whether the fluid is contained within a cyst or in the general peritoneal cavity. This also requires some experience in order to insure accuracy. Fluid in the general peritoneal cavity gives in fluctuation a wave which pervades the entire cavity, and this can be felt by placing the hand on different parts of the surface. When, on the other hand, there is even a thin cyst wall it is sometimes possible to distinguish the limit of the wave movement. Fluctuation can also be developed by introducing a finger into the vagina, and if the cyst occupies the pelvic cavity, fluctuation can be obtained by percussing the abdominal wall and feeling the wave with the finger in the cavity of the vagina.

I desire also to call your attention to a wave-like movement which is sometimes obtained on percussing the abdomen, and which is known as the fat wave. This wave is found in patients with very fat abdominal walls, this fat being loosely held in the meshes of the fascia. It is important that this be borne in mind, for errors in diagnosis have been made by the confusion of this wave with that of fluctuation.

We have so far examined the abdominal surface. It has been examined with the eye so as to determine its contour and outline. It has also been examined by palpation and percussion. The ear has been placed on the surface and auscultation has been performed. The effort has also been made to determine whether the fluid is contained within the peritoneal cavity or in a cyst in the cavity. This has been done by eliciting the fluctuation wave.

I might say, in addition, that it is desirable to employ mensuration—that is, measuring the enlargement. This can be done by a tape-measure passed around the abdomen at the level of the umbilicus. Then, at the point of the ensiform cartilage, also at the point of greatest enlargement, which is usually below the umbilicus, and a measurement may also be taken just above the pubes. In this way the circumference at these various points can be ascertained and recorded. It is also important to note the distance from the ensiform cartilage to the umbilicus and from the umbilicus to the pubes. If it is necessary to examine the patient from time to time, these measurements can be repeated in order to determine the variation in size.

Having completed the external examination, we are now prepared to make a vaginal examination. I take the opportunity of saying at this point that no one would be justified in undertaking abdominal incision without completing any examination which has been made by a vaginal examination. I can recall at this moment one case in which this step was neglected and the abdominal cavity was opened and a pregnant uterus found. A vaginal examination in this case would undoubtedly have revealed the existence of pregnancy, and the patient would have been saved the rather dangerous operation of abdominal incision. For the purpose of a vaginal examination the patient should lie on her back and should afterwards be changed to the side. The finger, well anointed, should be passed into the vagina and at once seek the cervix. Having examined the cervix, the finger should be swept around the neck, and as it is withdrawn palpation should be made anteriorly, laterally, and posteriorly. Then bimanual examination should be practised, with the finger of the right hand in the vagina, pressure being made over the surface of the abdomen with the left hand. In this way information can be obtained in regard to the connection of the growth with the uterus. Other points of information which can be obtained in this way are the following: A cystic tumor occupying the pelvic cavity can be felt through the vaginal wall. A solid tumor can be felt in the same way. So with the finger introduced into the vagina, the occupation of the pelvic cavity can be determined through the vaginal walls. As I have already stated, fluctuation can be obtained with the finger in the vagina, percussion being made on the surface of the abdomen with the other hand.

It is also necessary to introduce the sound into the uterine cavity in order to determine the condition of the uterine canal. It is desirable that beginners in performing this operation should use the speculum. After years of experience, one may be enabled readily to introduce the sound without danger into the cavity of the womb without a speculum, the finger of one hand being introduced into the vagina and placed on the cervix and the sound being carried along this as a guide. There are so many dangers, however, which present themselves in the introduction of the sound in cases of uterine tumors, and, indeed, even of other tumors connected with the uterus, that it is desirable to use the greatest care in the introduction of the sound into the canal. It should not be forced, but the way should be felt. It frequently happens that there are displacements of the uterus by reason of the pressure of the growth, whether this be solid or cystic in character. With regard to the presence of cystic growths, the information obtained by passing the sound into the uterus relates rather to the mobility of the uterus and to the fact of its being drawn up from the cavity of the pelvis or forced down into the cavity. On the one hand, we may assert with reasonable accuracy that adhesions exist if the uterus is found to be drawn up into the cavity of the pelvis and held in a fixed position; and on the other hand, we may infer that the cyst is impacted in the cavity of the pelvis, if the uterus is in a state of flexion, either antero or retro, and is immovable in its position. In fibroid growths, especially of the submucous and mural varieties, the uterine canal is notably elongated, and the sound introduced into the uterus will give very valuable information as to the seat of the fibroid tumor.

With the speculum we can ascertain the color of the mucous membrane of the vagina and the color of that covering the cervix. This is regarded as a matter of importance, as in the pregnant female the color is of a purplish hue, which is thought to be diagnostic. Another point to be ascertained with the finger in the vagina is the condition of the cervix, as to softness or hardness.

In addition to the examination by the vagina, it is sometimes desirable to make an examination by the rectum. By this means the existence of growths which cannot be readily reached in the vagina can be determined. It is, of course, necessary that an enema should have been administered beforehand in order to unload the lower bowel.

It is also well to complete the examination by the introduction of the sound into the cavity of the bladder. With this instrument in the bladder, and the finger in the rectum, bimanual manipulation can be made which will assist in the detection of tumors occupying the pelvic cavity.

In order to illustrate the points to which I have alluded, I shall next examine the patient now upon the table. She has been prepared by the removal of all unnecessary clothing and of all constrictions around the waist. The abdomen is exposed, and on inspection we observe that it is irregular. In the median line there is a projection, and on the right side there is another. The observance of two irregular points upon the surface gives us certain information in regard to the nature of the growth which occupies the cavity of the abdomen. It excludes certain conditions. For instance, pregnancy. In pregnancy there is a uniform enlargement of the abdomen, and the surface is not irregular as in the present instance. Inspection does not enable us to say whether these irregularities are due to pedunculated fibroid tumors or to exogenous cysts forming part of an ovarian cyst, but it does enable us to say that this is not a case of pregnancy and not a case of simple cyst.

Palpation is the next method to be employed. By making pressure with two or three of the fingers over different parts of the swelling, I can easily feel beneath the abdominal wall a hard, resisting mass which is not elastic. This would seem to indicate that the growth is solid and not cystic. Palpation elicits the same sensation over all parts of the growth. We cannot say positively from this examination that this is not a very dense multilocular cyst. You may be able, after much experience, to determine very slight shades of difference in the elasticity, which can be obtained even in cases of dense multilocular cysts. So far as I can ascertain from palpation, I am inclined to believe that we are dealing with a solid tumor and not a cyst. Not only do the fingers determine the presence of a hard, unyielding mass, but those projections which were noticed on inspection can be further outlined. Slightly to the right of the median line is a large mass which appears to be attached to the uterus by a broad pedicle. On the left is another mass, and below the tumor on the right there is a small mass which seems to be somewhat movable. This would seem to indicate that these growths are fibroid tumors which are attached to the body of the uterus by either broad and short or narrow longer pedicles. In the former case being called sessile and in the latter pedunculated or pedicalated growths.

You will observe that the brownish line reaching from the umbilicus to the pubes, which has been referred to, is present in this case.

Next, I shall practise percussion. Beginning at the ensiform cartilage, and percussing in the median line, there is, as you observe, resonance down to this point, about two and a half inches above the umbilicus. Here the sound suddenly changes into that of dulness or flatness. As I pass downward in the median line, the same flat sound is elicited below the umbilicus. As I pass on either side of the median line from the point before mentioned, the dulness is found to exist there also. The patient is next turned on the left side, and percussion performed over the right lumbar region and lateral side of the abdominal cavity. At this point we find the dulness which belongs to the liver, and as we pass downwards we reach the resonance belonging to the ascending colon. Turning the patient now upon the right side and percussing over the left side, we find in the posterior part of the lumbar region, the resonance depending on the presence of the descending colon. As we come toward the median line, the sound becomes dull or flat, showing that this mass projects more into the left side than into the right side of the abdominal cavity.

Testing for fluctuation, I find it impossible to obtain any wave. We can therefore say that there is no fluid, either in the abdominal cavity proper or in any cyst contained in the abdominal cavity.

Continuing the examination, I place my ear over the abdomen at the point which I have before mentioned. I am, however, unable to hear any sound which may be regarded as indicating the presence of a fœtus in the uterus or any aneurismal bruit which would be found in dilatation of the aorta. Auscultation, therefore, gives altogether negative signs in this case.

Examination per vaginam shows that the uterus is small. The cervix is slightly elongated and that of a woman who has never been pregnant. The uterus is fixed and immovable in a position of marked retroflexion. Palpation through the vaginal walls reveals the presence of hard, unyielding masses. These, so far as can be ascertained, are attached to the body of the uterus. Owing to the displacement of the uterus, it is impossible to introduce the sound completely. It simply passes into the cervix, but not beyond the internal os.

Rectal examination has not been made, nor has any examination by the bladder been made, as the symptoms were sufficiently prominent and characteristic to enable us to arrive at a conclusion without employing this manipulation. In any case of doubt, however, it is necessary that examination by the rectum and bladder should be made as before stated.

Having passed in a systematic manner through the different steps of the examination, we are enabled to arrive at a conclusion in regard to the nature of this growth. In other words, we are prepared to make the diagnosis. From what I have seen, and from what I have felt, I am prepared to say that we have here fibroid tumors which are of the subperitoneal form. Whether the uterus itself is involved to any great extent cannot be positively determined, owing to the impossibility of introducing the sound. It is, however, quite possible that in addition to the subperitoneal form of fibroid tumors there is also the mural form or that in which the body of the uterus is affected.

Before passing to the question of treatment, I would say that there are three varieties of fibroid growths, or if you choose to call them so, of fibro-myoma or fibromyomatous growths. These varieties are the subperitoneal, in which the tumors lie beneath the peritoneum; the interstitial or mural, in which the tumors are located in the substance of the uterus itself, and the submucous, in which the tumors are situated beneath the mucous membrane of the uterine canal. In the subperitoneal variety the tumors project from the surface of the uterus, being covered with a layer of peritoneum and sometimes attached to the body of the organ by a broad and short pedicle, in which case, as I have said, they are called ses-

sile growths, or by narrow and long pedicles, in which case they are called pedunculated growths. In those cases in which the pedicle is small and long, the mass can be readily moved about the cavity of the abdomen. Not only so, but it falls about if no adhesions exist, as the patient changes her position from side to side or rises from the recumbent to the erect position. In the case of mural tumors, which, as already stated, occupy the substance of the uterus, the organ is uniformly enlarged. Where they exist without the presence of subperitoneal or submucous tumors, the uterus is uniformly enlarged, as is found in pregnancy. In the submucous variety the growths form beneath the mucous membrane and project into the cavity of the uterus. Sometimes they get into the canal, and the contraction of the muscular fibres forces them on down until they escape from the cervix, forming what are known as polypi, the pedicle being in these cases elongated so as to permit the growth to pass into the cavity of the vagina. Frequently these submucous fibroid tumors are very large, and they do not pass into the canal and become pedicalated, but distend the cavity of the uterus and change the direction of the canal.

The symptoms in the submucous and mural varieties of fibroid tumors are largely connected with the menstrual flow, and they relate to an increase of the flow. I have had some patients who lost enormous amounts of blood at these periods. This is a prominent symptom, and should always lead to a suspicion of this form of growth. Hemorrhage at the menstrual period is not so marked in the mural as in the submucous variety. This symptom may be entirely absent in the subperitoneal variety of fibroid tumors.

I next come to the question of treatment. At the present day, various methods of treatment are practised. In the first place with regard to medication. Mural and submucous growths are amenable to treatment by means of such remedies as ergot, which, by contracting the bloodvessels of the organ, diminish the nutrition, and in that way limit the growth of the tumor. There has been sufficient experience obtained in the use of ergot and its preparations to warrant the conclusion that these forms of growth can be positively limited. Whether or not they can be ultimately removed, is still a question, but their growth can be checked. Ergot is not of as much value in the subperitoneal variety, especially in the pedunculated form, where the pedicle is long and narrow. It may be of some service where the pedicle is broad, as in the sessile growths, and where the effect of the remedy can reach the bloodvessels of the attached mass. The muriate of ammonium was employed by the late Dr. W. L. Atlee, who regarded it of value in the treatment of fibroid growths of the uterus.

After these remedies, operative interference may be employed, but there are two very important questions or conditions to be considered before any operation is to be decided upon. In the case of fibroid growths in which the menstrual flow is so great as to drain away the life of the patient, it may be justifiable to interfere with the knife. There is also another condition which would warrant operative measures, and that is the enormous size of the mass, making it a burden to the patient too great to bear.

In regard to operative interferences, the menopause can be anticipated by the removal of the ovaries. If any operation is to be performed, the removal of the ovaries, which is much less dangerous than extirpation of the uterus, is the one to be adopted. There are to my mind very grave objections to the performance of operations for the removal of fibroid masses which involve the body of the uterus or which are attached by very broad pedicles to it, and which are adherent to the viscera or abdominal wall.

A patient with a uterine fibroid can enjoy life and the growth can exist indefinitely without interfering with health. I have at this time under my care a number of patients suffering with fibroid tumors in whom I have practised the hypodermic injection of ergotine, or the aqueous extract of ergot, for a number of years. In one of these cases, I have used ergotine for the past eight years. Measurement of the abdominal enlargement in this case shows that the growth has not increased. It has, on the other hand, not markedly decreased. The patient does not loose much blood during her menstrual period, and is not rendered uncomfortable by the presence of the tumor. She is able to take part in all the enjoyments of her home, to ride out in her carriage, and to enjoy the company of her friends. I am quite sure that if I were to interfere in this case with a surgical procedure, I should terminate the life of my patient. In another case, in which I used ergot for three years, a most desirable result was obtained. In this instance, the growth was of the submucous variety. After the lapse of nearly three years, I observed that the mass was softening; and on palpation and percussion, fluctuation could be distinctly obtained. I also examined the mass from the cavity of the uterus, and found that there, too, it was softened, and fluctuation could be obtained. I therefore determined to incise the wall of the canal, which I did, and a mass of offensive fluid escaped, containing broken-down débris of muscular and fibrous tissues. My patient suffered greatly from pyæmic symptoms, and was very ill for a number of days; but by the vigorous use of antiseptic methods, washing out the cavity with antiseptic agents, as the solution of carbolic acid, surrounding her with the best hygienic conditions, and by the employment of tonics and stimulants, I was able to carry her through this critical period occupied by the evacuation of this large cavity formed by the breaking down of the tumor. Other instances of this kind have been recorded in which the effect of ergot has been markedly seen. I can only explain this transformation of the solid growth to the fluid or semi-fluid condition by the cutting off of the nutrition of the growth, and the production of positive gangrene.

There are instances on record in which incision of the lining membrane of the canal has been made and ergot afterward given. In this way, submucous fibroid tumors have been delivered. When the delivery has not been complete, the surgeon has interfered, and has removed the mass by cutting away portions of it at different times. This operation is attended with many dangers. Some of these dangers result from septic infection and shock. There is also the danger of the occurrence of hemorrhage.

From the examination of the case before you, the treatment which I should adopt, would be the long-continued use of hypodermic injections of ergotine, and this failing, the performance of oöphorectomy. I may

say, in regard to the hypodermic injection of this remedy, that the injections should be made in the abdominal wall; and in order to avoid the occurrence of abscess, it has been my practice to carry the needle of the syringe deeply into the tissues, not stopping until the muscular structures have been reached. In none of the cases in which I have used ergotine in this way have I met with abscess. As a precaution, I have frequently painted tincture of iodine around the puncture made by the needle. The form of ergot used is that known as Squibb's aqueous extract, which is made in a solution, the strength of which is one grain to the minim. Of this solution, I have given 25, 30, and 35 minims without producing any undesirable symptoms.

ORIGINAL ARTICLES.

EXCISION OF SUPERIOR MAXILLA, WITH REMARKS[1]

BY GEORGE A. PETERS, M.D.,
ATTENDING SURGEON TO ST LUKE'S AND CONSULTING SURGEON TO NEW YORK HOSPITAL.

J. J. M., æt. 55, married, born in Canada, has been a planter on the island of Cuba for several years past; came to New York for surgical relief, and placed himself under my care. He was seen in consultation by Dr. T. M. Markoe, Dr. R. F. Weir, and Dr. Chas. McBurney, my hospital colleagues. Not being willing to do a grave operation in a hotel, I persuaded him to enter St. Luke's Hospital, which he did May 4, 1884.

The history of his case is as follows, viz.: No history of any hereditary disease in his family. General health has always been good. No history of venereal disease. About two years ago, while riding over his plantation on the back of a mule, superintending some laborers, he was thrown to the ground, striking heavily upon the left side of his face, bruising it severely; at the same time he suffered severe contusion of the leg and back. His recollection is that the contusions of the lower limbs occasioned much more pain and inconvenience than the injuries of his head and face.

Before any tumor of the face was observed, the sight of the left eye "became poor," and there was an increase in the lachrymal secretions. "The eye itself seemed to be stiff." At night there was a slight discharge, which dribbled over the face during sleep. Has never had epistaxis. Began soon after this to complain of frequent attacks of pain above and around the left orbit. About eight months ago he observed a small swelling on the left alveolar process, above the first molar tooth. This tooth was extracted by a dentist in Cuba, who stated that there was some discharge from the cavity, and that the root of the tooth was diseased. This operation afforded some relief for the time.

Two months later, he had a severe chill, followed by a high fever. He then noticed a swelling on the roof of the mouth to the left of the median line, about the size of a hazelnut, and the left cheek now became much swollen. This, however, soon subsided, except for a small swelling which remained in the centre of the cheek. This tumor has gradually increased in size, forcing the cheek outward, projecting into the nasal cavity, and pressing down the hard palate. At about this time, he came under the care of a surgeon in Havana, who had great local reputation. He told him that he had a polypus in the left naris, which he then and there proceeded to remove with forceps and scissors. The result of the operation, as described to me by the patient, was a few shreds of mucous membrane, but no well-defined growth. He also plunged a bistoury into the tumor on the roof of the mouth, and removed a small section for future examination. On the following day his surgeon called and informed him that a thorough microscopic examination confirmed his diagnosis, and assured him that the whole affair was merely a polypoid growth, and was not at all malignant—in fact, that he was virtually cured.

Notwithstanding this, the tumor continued to increase in size and to give him much pain. About the middle of the month of February, 1884, I found myself in Havana in search for health. I was asked to see Mr. M. professionally. Recognizing the presence of a malignant growth, I arranged with him that he should "put his house in order," and follow me to New York, prepared to submit himself to whatever treatment should there be advised. Late in the month of March he was in Havana, expecting to come immediately on to New York, as agreed. At this time he fell again into the hands of the surgeon who removed his "polypus." He now told him that the progress of the disease had at length revealed that the tumor was an aneurism, and proposed to cure him by electrolysis.

The needles were introduced and the current applied. The result was an immediate increase in size and a very rapid growth. He was now utterly discouraged, and, as soon as he was able to travel, "took ship" and presented himself to me for treatment.

Condition when admitted to hospital was as follows, viz.: Since the introduction of the needle there has been a continuous discharge from the old cavity in the alveolar process into the mouth, which discharge has some odor. Breathing through the left nostril is somewhat obstructed. General condition of health is very good; appetite fair; bowels regular. On examination, the whole of the left superior maxilla is found to be occupied by a tumor, about the size of a large peach, which protrudes outwards just below the prominence of the cheek, and extends upwards to the ridge of the orbit. The left eye protrudes slightly. In the mouth a prominence is discovered from the palatal process just below the antrum. The first and second molar teeth upon that side have been extracted; and into the cavity formerly occupied by the first molar a probe can be passed for a short distance, and there is a continuous discharge from it. The skin of the face is normal in color and feel. The surface of the tumor is perfectly smooth, and feels soft to the touch, as though the bone had been absorbed.

May 7, 1884, operation: At 2.30 P.M., assisted by Drs. Bull and McBurney, I operated. The patient

[1] Read before the New York Surgical Society, Dec. 23, 1884.

was etherized by the rectum, so that I should have no delay or obstruction caused by the apparatus used in etherization by inhalation. The flap for exposure of the bone was made after Ferguson's method. An incision through the skin, well down upon the surface of the bone, extending from the inner angle of the eye to the outer limit of the orbit, parallel with and a little below the infraorbital ridge, and the other commencing at the nasal extremity of the first, and carried down along the side of the nose, around its ala to the columna nasi, thence down to the middle of the lip, including its entire thickness. The flap was dissected up rapidly, and turned down. The bleeding points were secured with clamps, the soft parts dissected away from the nasal process, and also the cartilage of the nose from the nasal notch of the maxilla. The left middle incisor tooth was then extracted. The malar bone close to its junction with the maxilla was notched with a small saw. The nasal process of the inferior maxilla at the inner angle of the orbit was treated in the same manner with the saw. The strong cutting bone-pliers were now used for completing the section of the bone, at the outer angle through into the spheno-maxillary fissure, at the inner angle, just below the groove in which lies the lachrymal sac. Two incisions were now made over the hard palate, one posterior and transverse, along the suture between the palatine bone and the horizontal plate of the maxillary bone, the other extending from the inner extremity of the first, along the longitudinal suture, uniting the horizontal plates of the upper maxillæ to the alveolus from which the incisor tooth was extracted. The hard palate was now divided by the large straight pliers, one blade through the nose and the other through the mouth. The whole tumor mass, which was soft and friable, was seized with the fingers and thumb, and twisted loose from its attachments, the scissors being used when required. All suspicious looking tissue was scraped away with a sharp-edged spoon until the surface in view looked healthy and normal. The periosteum was detached with a "seraper," and lifted up from the bone forming the floor of the orbit, so that after the bone was removed well back in the orbit, there should be a support left for the eyeball. The palati bones were left *in situ*, with an uninjured uvula and curtain.

The hemorrhage during the operation was but little, although the tumor itself was exceedingly vascular. Only three animal ligatures were required. The walls of the cavity were covered with iodoform gauze, and the cheek was filled out with three tampons of carbolized gauze, the strings attached to them being brought out through the mouth. The wound through the lip was secured with one harelip pin suture and one silver wire suture. The remainder of the flaps were held in place with continuous and interrupted sutures of fine black silk, and the line of incision was painted over with flexible collodion in which iodoform had been dissolved (one-half drachm to one ounce).

Patient was sent to his room. At 4.50 P.M., he raised himself in bed and appeared partially conscious. At 5.15 P.M., he attempted to speak. Had a movement from the bowels at 5.20, which had some form. Another at 6.30, which was thin and slimy. Neither passage contained any trace of blood. All oozing of blood from wound ceased at 9.30 P.M. There was no vomiting. Rested very quietly during the night, sleeping most of the time. Swallowed small quantities of ice water.

Went on to recovery without any drawback. The mouth was frequently cleansed with boracic acid solution. The tampons were removed from the cavity at the end of the third day, and the cavity packed loosely with carbolized gauze.

Harelip and silver sutures removed on third day. Union by first intention took place throughout entire incision, and all sutures were removed before the expiration of a week.

Was discharged cured May 22, 1884, two weeks after the operation. Only on two days during his residence in the hospital did his temperature reach 99°, and the highest pulse-beat recorded was once 104.

Pathologist's Report: Tumor received from St. Luke's Hospital on May 7, 1884, is connected with the alveolar process of the superior maxilla, left side, and as large as a hen's egg. It is soft, friable, and differing in consistency in different places. It destroys for a considerable extent the bony alveolar process and some of the teeth. It is composed of lobules of epithelial cells of irregular size, supported by a very delicate stroma. The epithelial cells at the periphery of the lobules next to the stroma are low cylindrical; elsewhere they are small, flat, or cuboidal, and distinctly nucleated. Numerous small, round, and spindle cells are seen in the stroma, which also show a goodly supply of bloodvessels.

Diagnosis: Lobulated Epithelioma (Ferguson). After leaving St. Luke's Hospital the patient recovered his health and strength rapidly. The deformity resulting was very little. The lines of incision were scarcely perceptible. His chief inconvenience was from the opening in the roof of the mouth, communicating with the nose, which rendered his voice indistinct, and permitted regurgitation of food so as to annoy him somewhat.

A dentist was consulted, who made a thin plate of gold with teeth attached, which, when in place, obviated the embarrassment, and was worn with much comfort. It was a difficult matter to secure the plate in position so that it would not "drop down." A piece of mechanism was contrived which was very ingenious and effective. To the upper or convex surface of the gold plate a button was attached by a hinge—the button stood up from the surface at a right angle—when the plate was placed in position this button projected into the cavity, it was then made to hook over and clasp the bony palatine plate of right maxilla at edge of the wound by pressing upon one of the molar teeth in the plate which was connected with the button by means of a spring. The plate was easily removed for purpose of cleansing and held very firmly in place. This apparatus he was enabled to wear during the entire time between soon after the first operation and the time he returned to his home in Cuba.

Copied from case-book, New York Hospital: Recurrent carcinoma of the face. Service of Dr. Geo.

A. Peters. Aug. 24, 1884, admitted to New York Hospital.

J. J. M., æt. 55 years. Born in Nova Scotia. Married. Planter.

Family history negative. Has always enjoyed good health until two years ago, when he fell from his horse, striking the side of his face. Last November a swelling appeared in inner side of left hard palate, and gradually increased in size. Patient was operated upon on the 7th of last May, in St. Luke's Hospital, by Dr. George A. Peters, and the left inferior maxilla removed. Recovery good. Three weeks ago a tumor reappeared in the left malar region, and has been growing rapidly ever since.

On admission, general condition good. Examination shows a tumor about the size of a half a pullet's egg, situated below the outer half of left eye, over molar region. The mass is hard, firm, elastic to the feel, and occasionally painful; is attached to subjacent tissues. Skin over the tumor is discolored, but not adherent to it.

Operation, August 27th, was done by Dr. Peters. Etherization was started by inhalation, and continued per rectum. A curved incision was made through the skin over the swelling, running toward the nose; flaps raised, and fleshy mass of the tumor removed. With the rongeur a considerable portion of the zygomatic process was gnawed away, and the prolongations of tumor tissue were scraped away from beneath that process and from the temporal fascia. Hemorrhage during the operation was considerable. Several small sized and one large bleeding point were tied with animal ligature. Rubber drainage-tube was inserted; the wound was sutured with fine black silk. Three ounces of ether were used by the rectum during the entire operation, which lasted for an hour and a half. The second operation did not open into the cavity left as a result of the first one.

Rallied well from the ether and operation; no vomiting, and no rectal symptoms. There was considerable œdema of conjunctiva and eyelids; no pain.

Drainage-tubes removed about thirty-six hours after operation. On the third day the sutures were removed. Union was complete except where the tube emerged; here a small sinus remained open for a few days, when it closed. At the end of a week from the time of operation, the patient left the hospital and went to his hotel. Returned to his home in Cuba, Sept. 13, 1884.

Pathological report by Ferguson, of New York Hospital:

"Examination of the tumor shows it to be a typical epithelioma. Large masses of flat cells are seen in a small amount of fibrous stroma, in which are many young cells of inflammatory origin."

Believing that rectal etherization would be especially desirable in this case by leaving the face unobscured by cone or any apparatus, I devoted some time to contriving a method which should be both safe and sure. Administration of ether by this channel had been but little practised, although fortunately comparatively much had been recorded in the journals. The chief dangers seemed to be either from overdistention of the bowels with ether vapor, or tenesmus with bloody discharges from the rectum, caused probably by fluid ether being forced through the tube and deposited in contact with the mucous membrane, producing inflammation. Experiments had demonstrated that the cool rubber tube produced rapid condensation of the vapor driven through it. The amount or rapidity of condensation did not seem to depend either upon the length or calibre of the tube. Ether boils at a temperature of 96° F. Theoretically, it seemed that if the vapor were superheated it would condense rapidly. The temperature of the water in which the vaporizer was immersed was kept as nearly as possible at a temperature of from 103° to 105° F. If the temperature is raised to 120° or 130°, the ebullition becomes so active as to drive over the fluid ether in considerable quantity.

Dr. Ogden C. Ludlow, who occupied the position of senior walker in St. Luke's Hospital, contrived a very simple and ingenious apparatus, by means of which we were enabled to secure the desired results.

It may be described as follows, viz.: two glass vials, of a capacity of from six to eight ounces. One vial, intended as reservoir for containing the supply of ether in sufficient quantity to last throughout the entire operation, should be marked with graduate lines, so that the amount used may be accurately measured. This is connected with the second vial, intended to be used as the vaporizer, by a rubber tube with a forcing bulb, as in Davidson's syringe. Vial No. 2 is placed in a jar of water with a thermometer, so that the water may be kept at the required temperature. To a curved glass tube projecting through the stopper of vial No. 2 is attached a rubber tube, about two feet long, on the distal end of which is a nozzle for introducing well into the rectum. Into this rubber tube, about eight inches from the nozzle, is inserted a short glass tube, from which the apparatus can be easily detached when the vapor is not needed. The glass also enables one to discover when fluid ether is driven through it. Through the cork stopper of vial No. 2 a second glass tube is passed, which tube receives the rubber from vial No. 1, through which ether is fed as required from the reservoir.

Here we have a very simple and easily managed apparatus.

When a sufficient quantity of vaporized ether has passed into the rectum, the tube is slipped off from its glass attachment near the anus and left in situ. The connection can be rapidly reëstablished when vapor is needed. This tube left in the rectum has also the advantage of affording a ready escape for any excess of ether vapor which may have been driven on, or for gases generated in the bowels.

To show how satisfactorily the apparatus works, I will here read the report of what was very carefully observed and recorded at the time by Dr. Ludlow, who had the sole charge of the administration of ether in the case.

"May 7th, at 2.30 P.M., patient was etherized per rectum, half an ounce of brandy having been given previously. At the beginning, pulse 104. One and a half ounces of ether were then forced into the vaporizer. Within one-half a minute he tasted the ether in his mouth, and was at once seized with a

desire to evacuate the contents of his bowels, although two enemata had been given in the morning. In five minutes the muscles of his arms were relaxed, and the conjunctiva but slightly sensitive. After another minute he opened his eyes, spoke, and turned over on the table. Another ounce of ether was then forced over into the vaporizer. The ether cone was then placed over his face. He struggled for a short time, but was completely anæsthetized in eleven minutes from the commencement, when the cone was removed. Ether was administered per rectum for fifteen minutes, when the tube was disjointed. This was followed by a discharge of ether and foul-smelling gas through the tube. After this, the tubes were connected for one or two minutes at a time; making the total time of actual etherization thirty minutes. The last charge of ether vapor was given one hour and thirty-two minutes from the start, but the operation was not completed for thirty minutes more. At the end of two hours and ten minutes, the conjunctiva became sensitive and the arms commenced to stiffen. Pulse 120, and fairly strong. Amount of ether used, three and a half ounces."

For the second operation, done August 27, 1884, the ether cone was applied over the face until he came perfectly under its influence, when it was removed. The tube was then introduced into the bowel, and rectal etherization was employed throughout the time of the operation. The apparatus used at the New York Hospital was extemporized from the materials at hand, and was by no means as complete as the one described above. It answered the purpose, however. Patient was anæsthetized for an hour and a half; only three ounces of ether were used, and this only for a few minutes at a time, connecting the apparatus only when the effect of the anæsthetic seemed to be passing off.

My experience in operating upon the mouth, or its neighborhood, involving either complete or partial excision of the jaw-bone, notably in several cases of extirpation of pharyngeal tumors of a malignant nature, reports of which have been made before this Society, led me to appreciate the great hindrance to rapid or thorough removal caused by the presence of the ether cone as generally employed. The operator is frequently obliged to interrupt his manipulations at a critical point in order that more ether may be given, or the mouth and throat cleansed of accumulated blood, etc. In order to obviate these hindrances, and also to render it safe to use the actual cautery where required, I had on several occasions performed laryngotomy as a preliminary step. This enabled me to administer the ether through a tube inserted in the wound, and extending to the reservoir of ether at any chosen distance. This procedure also enables the operator to plug the fauces, and thus prevent the influx of blood, etc., into the air passages. The cases in which I had used this procedure were so entirely satisfactory that I resorted to it without any hesitation. I have seen no bad results from the opening in the windpipe, which opening I always close before the patient is removed from the table. When rectal etherization was first brought to my notice, I recognized in it a less formidable adjunct, provided it should be proven reasonably safe. By it we accomplished all that is afforded by laryngotomy, save that it will require much greater care in packing the posterior fauces.

The use of the rectal method in the two instances above recorded, encourages me to believe that, with proper precautions in its use, we have a method which is both safe and sure.

Previous to the year 1826 considerable portions of the upper jaw had been removed by surgeons in various countries, notably by Dr. Alexander W. Stevens, of this city, who, in August, 1823, removed a large portion of the upper jaw for a disease of the antrum, and seven years afterward his patient was in perfect health. Dr. Stevens claimed that he was the first to operate upon the principle of cutting through the sound and not the diseased parts.

Dr. David L. Rodgers, of New York, in May, 1824, successfully removed the greater portion of the superior maxilla for osteo-sarcoma.

Mr. Lizars, of Edinburgh, in 1826, first proposed the entire removal of the upper jaw. In 1827 he attempted to carry his plan into execution for removal of a medullary sarcoma of the antrum, but was obliged to desist on account of the hemorrhage.

On May 26, 1827, Gensoul, of Lyons, removed the entire superior maxilla, with the whole of the palate bone. Patient recovered.

At length, in August, 1829, Mr. Lizars performed his second operation, which was successful. Surgeons of the present day do this operation as opportunity offers with generally good results.

Resections of portions of the superior maxilla, for the purpose of securing access to tumors in posterior nares or fauces, is frequently practised. The method of incision of the soft parts in order to reach the bone is a matter of importance, and deserves consideration.

Mr. Lizars used an incision across the cheek, from the angle of the mouth to the malar bone; or, when the tumor was very large, employed an incision through the lip into the nostril, with a vertical cut on the malar bone. With the saw and bone forceps, the maxilla was separated and removed. This was the cut made by most surgeons, until Sir William Fergusson proposed an important modification in the method of procedure. The deformity resulting from the methods in vogue, led him to devise the plan of carrying the incision solely through the medial line of the lip into the nostril, in the manner used by me and described in my note of the operation.

In the operation for removal of the superior maxilla, the hemorrhage is, in some cases, very profuse; but if done rapidly and dexterously, securing the larger bleeding vessels with clamps, the surgeon need not fear fatal bleeding.

I will bring my paper to a close with a few remarks as to the class of cases in which the operation is justifiable.

Necrosis of the upper jaw, whether as the result of injury or disease in neighboring soft parts, syphilis, etc., requires operation sometimes even to the extent of removal of the entire jaw.

Non-malignant tumors of the upper jaw, as fibroma and enchondroma, occasionally attain a size requiring removal of the entire bone.

Hyperostosis of the jaw, which consists primarily in periosteal inflammation, leading to the deposit of new bone, and the expansion and filling up of the original osseous structure, is unconnected with syphilis or stroma, and appears to be beyond the control of remedies; and not infrequently reaches so great a size as to cause much deformity, and justify the removal of the entire maxilla.

It is in connection with malignant tumors of the upper jaw that the surgeon is often called upon to decide as to the propriety of removal.

It is now well established by the experience of many operators that the operation, even when so radical as the removal of the entire jaw, does not result in a cure, we can predict with almost absolute certainty that the disease will return within a year. The temporary relief afforded in connection with the moral effect of the operation will, I believe, justify it.

In the case above narrated, both the patient and his wife declare that, although the disease has again appeared, and no further operation is contemplated, the relief from pain and horror, experienced after the operation, renders them satisfied that it was done.

When the patient sailed for Cuba, about the middle of September last, a careful inspection of the cavity, seen through the opening in the roof of the mouth, revealed a recurrence of the disease to a slight degree. Under date of December 16th, I have heard by letter that the disease is progressing slowly. Mr. M. is decidedly of the opinion that the growth is retarded by the use of the fluid extract of red clover blossoms, which he has used diligently ever since the operation, in half ounce doses three times a day.

FORMER VIEWS AS TO THE CONTAGIUM OF CHOLERA.

TREATMENT STILL INDEPENDENT OF ITS ETIOLOGY.

BY EZRA M. HUNT, M.D.,
OF TRENTON, N. J.

Now that the germ theory of disease, and especially its relation to Asiatic cholera, is attracting so much attention, it is neither uninteresting nor unprofitable to note the earlier history of these investigations. While it must not discourage us as to future possible attainments, it may so moderate our zeal as to lead us more accurately to weigh the significance of what has been discovered and to assign to it only its real prominence.

As long ago as 1838, Boehm made some very definite observations. In the ninth report of the Medical Officer of the Privy Council of Great Britain (1866), Dr. John Simon very forcibly calls attention to these observations. "If," says he, "the doctrine of a cholera fungus should hereafter be substantiated, it will probably be conceded that Boehm deserves the credit of having first published a thoroughly valid account of the phenomena of cryptogamic vegetation in choleraic intestines and discharges, and that Hallier's researches do not better join on to the recent essays of Thomé and Klob than they might have joined in 1838 on those of Boehm. The fifth section of his admirable little book describes as almost constant that the whole extent of the intestine (but generally the large intestine least) teems with a vegetation of microfungi; that innumerable round and oval or more elongated corpuscles are to be found in all the vomit and dejections as well as in the canal, sometimes single, sometimes two, three, four, or more joined end to end, as links of a chain, and these chainlets sometimes branching; that such forms are held together in mucous floccules and come best to light when liquor potassæ is used; that within the small intestines they are often so numerous that not the smallest specimen will fail to show numbers of roundish fungic forms amid the débris of the epithelium. He appends an illustration, which shows quite unquestionably the forms of cryptogamic growth, and refers for similar forms to Schwann's then recently published investigations of yeast."

In a pamphlet published in London in 1833, Dr. Tytler had so far connected a fungus of the rice plant with cholera as to attract much attention. It led Hallier, in 1866, to raise rice plants, of which in their early stage of growth he made longitudinal sections, and found fungus-threads in great numbers perforating the epidermis of the plant in several places above the juncture of the rootlets. By the aid of glycerine a multitude of cryptococcus cells were seen, and had the same characters as when known urocystis grows within cereal plants. While not proving the identity of the parasitic fungus with the cyst-bearing plant, he did show that a form of the same type could be produced in rice watered with cholera evacuations. (Buchanan, p. 515.)

The discussions in England in 1849 as to a so-called cholera fungus were very extended and earnest, as the journals and some disquisitions fully attest. It was in that year, too, that our own Dr. Mitchell, of Philadelphia, wrote "On the Cryptogamous Origin of Malarious and Epidemic Fevers." The Bristol Medico-Chirurgical Society had Drs. Britton and Swayne at work as a microscopical committee, and in their examinations of choleraic discharges had independently of one another observed often in very large number certain secular forms, "annular bodies," "cholera cells," etc., which they believed to form a connected series, and to be characteristic and causative of the disease. Mr. John Quekett, then an eminent microscopist, examined Mr. Britton's specimens from air, vomit, and dejections and "had no hesitation in stating that, in his judgment, they were successive stages of development of the same body, which he believed to be of a fungoid nature." Dr. Budd, then of Bristol, seems to have accepted these views, while Dr. Snow committed himself no further than to say that there was a something which being swallowed can increase and multiply within the stomach and bowels. Dr. Cowdell, of Dorchester, the year before, had sought to establish on theoretical grounds that cholera must depend on a microscopical fungus. At the time, the report made to the College of Physicians by Drs. Baby and Gull and Mr. Marshall was circulated more than the views and observations of these suburban practitioners; although Hallier himself (1866) very fairly,

as it seems to us, recognized them as bearing on the hypothesis of a vegetable parasitic origin.

To Dr. Ernst Hallier chiefly (Leipzig, 1867) must be given the credit of the earliest, most minute inquiry in this direction. The care which he took "to prevent the accidental introduction of other fungi into his experiments and his check experiments to detect possible errors," are still the admiration of those who now work with all modern facilities. The stools are described as having characteristic vegetable elements which consisted of a fine fungiform matter (Hefe) which floated, and of more highly developed spore-cysts which sank to the bottom. These spore-cysts are described as yellow or brownish bodies, consisting of a pale membrane enclosing highly refracting colored spores. The cyst wall undergoes a series of changes, ending in its rupture or solution, and the spores then become free. The spores, by progressive partition (a process which may begin before they leave the cyst), resolve into very small cells, grouped into balls and heaps, which Hallier calls "colonies" of micrococci. "The small cells of micrococcus constitute the fungiform matter which is the other vegetable element seen in the evacuations." Besides these two elements, torula-like bodies were found in smaller numbers, and were shown by experiment to develop from the micrococcus cells; nuclei growing within the ball or heap and sometimes constituting the greater part. Around some of these nuclei a very delicate cell-wall may be found, but to detect this glycerine must be employed. The "formation of these cells, which occur singly or in rows, marks a step toward a higher development of the micrococcus." Even this outline shows what studies were made in this direction as preliminary to discoveries announced more recently.

However important new observations may be in a biological sense, let us not too hastily conclude that they have given us any real information as to modes of prevention or treatment. Dr. Simon, in connection with the article of Dr. Buchanan (see Report), also refers to the writings of Prof. Pacini, of Florence, who, "from 1854 to the present time (1866), has described the choleraic processes as consisting primarily in the destruction of the epithelium and villi of the intestines by an infiltrative vibrional development, and has argued that these vibriones and their germs—molecules of less than $\frac{1}{25000}$ of an inch in diameter—poured forth in millions in the discharges of the sick, must constitute the contagium of cholera."

It appears to us that some of our more recent descriptions differ more in classification, and in a more correct nomenclature, than in actual observation, especially when we also come to read over the descriptions by several other observers. Is not this remark of Dr. Simon in 1866 still in order, "It appears to me that not only the mere *biorama* of the intestinal contents, healthy as well as choleraic, will have to be studied far more extensively than it has yet been, and in all its accidental variations, but also that, in the general study of zymoses, no doubt must remain as to the etiological *significance* of the low organic forms which attend the chemical transformation"?

Pacini quotes from Bloch a very graphic expression of the truth in calling this field of study the "infusorial chaos of the intestines." Some order has come out of this chaos, but we must still think not enough to determine etiological relations or to settle much as to prevention or treatment. The application of Koch's solution of corrosive sublimate is not a result of any new knowledge as to the comma-bacillus, and the ephemeral life of it when thoroughly dried has as yet, perhaps, no practical application beyond what has long been known as to the value both of heat and dryness in disposing of all vegetable organisms.

It is to be hoped that, in case cholera should come among us, the Government will be prepared to sustain skilled experimentation, such as was provided for at Havana as to yellow fever. But it is to be insisted upon more earnestly that every particular of protective quarantine shall be provided, so that at the point of embarkation and on the ocean there shall be inspection, and both "sick and well call," and that all passengers, if need be, come under the daily notice of the surgeon. If this plan were to prevail, and all concealment were to be avoided, no case of cholera from an eight or ten days' voyage ought ever to arrive at our ports. In prospect of possible arrival, municipal and other health officers have little time to study or to be in expectancy about that myriad life of disease in which "hovers a multitude of minute bodies, differing essentially in their nature and animated by forces generating forms, giving rise to most extraordinary phenomena."

Our hope is in the study of the history of the clinical phenomena. Whatever will forestall the entry of the dangerous particles; whatever will put the system, or the part invaded, in a condition unfriendly to their fructification, or whatever will, in a medicinal way, interfere with the multiplying process, is the thing to be sought. We have alluded to the knowledge of over a quarter of a century ago, to show that no great change of base has been made by any recent discovery, and also to emphasize the need of that kind of sanitary, medical, and administrative preparation which is worth more than any recent "study of germs," however helpful this may eventually be for medicinal and non-medicinal therapeutics.

SOME POINTS IN THE RELATION OF SYPHILIS TO PULMONARY DISEASES.

By JOHN FERGUSON, M.A., M.D., L.R.C.P.,
ASSISTANT DEMONSTRATOR OF ANATOMY IN THE TORONTO SCHOOL OF MEDICINE, TORONTO, CANADA.

That there is often a very close relationship between diseases of the lungs and syphilis has for considerable time occupied my attention. We have all met with cases of pulmonary trouble that may have baffled us to find a satisfactory cause. A case that is diagnosticated as phthisis occurs in one member of a family, all the others being in perfect health. There may not be the slightest trace of consumption in the ancestry; nor has the person, who comes under our care, been so employed as to lead to the suspicion that his disease has arisen from such employment.

The difficulty of tracing to their true origin such cases of chronic lung disease as these, when we can find no evidence of another case in the family record, is sometimes very great, if not wholly impossible. One or other of the parents or grandparents may have had syphilis, and the fact be beyond our reach. There is no doubt, however, that the offspring of such parent or parents suffer differently. One has eruptions of the skin, another caries of the bones, a third obscure and obstinate nerve lesions, while a fourth has, as I shall try to show further on, disease of the respiratory organs. Nor is it necessary that the syphilis be inherited to cause lung disease. The person who contracts syphilis may suffer thus in his own lifetime.

The first case that set me a-thinking in this direction occurred in the person and family of a school-teacher, aged, when he consulted me, twenty-eight. The examination of the chest gave only too certain evidence of phthisis. Not suspecting syphilis, he was treated in a manner calculated to benefit a consumptive; but I need hardly say that the result was far from being good. Near the close of his life, after he had been under treatment for a year, he informed me that seven years previously he contracted syphilis, and was treated for it during a period of about two months. On inquiry, I found that he had suffered very little with sore throat, and that the rash on the skin was but slight.

On learning this, he was put on anti-syphilitic remedies, but despite these he sank and died, as his friends believed, an emaciated consumptive; as I believed, a syphilitic with pulmonary lesions.

One of his children, a little boy, had died of a wasting condition before the father came under my care. The remaining children, two little girls, were aged five years and one year respectively. The elder of these was delicate, but being sent to live with an uncle she passed from my notice. The younger took on lung disease, which progressed rapidly, and the little patient died from a copious hæmoptysis, a rare occurrence in so youthful a patient. I must here state that the mother was a very obstinate person, and, believing the child to be consumptive and incurable, would have nothing done for it.

In these cases we have the appearance of wasting lung disease in a family whose blood relatives on both sides were perfectly free from phthisis. The only likely cause is the syphilis which the father contracted about six years before he consulted me first. At all events, if the syphilis in the father was not the cause of the lung disease in his own case and in those of his children, we have the coincidence.

Another family, from which some very important conclusions may be drawn regarding the relationship of syphilis and pulmonary diseases, came under my notice in the fall of 1882. The first patient from this family was a young man of about twenty-one years. He came to me on account of his consumption. On examining the chest there were well-marked evidences of disease. He coughed a great deal and expectorated freely. His pulse was frequent and his temperature 100° F. I inquired carefully as to his private life, but with entirely negative results, there being no suspicion that he had ever had syphilis. He was treated for some time in a general tonic manner, with very slight improvement. After my patient had been under my care for nearly three months, the father called one day to talk over the condition of his son. At this interview I drifted the conversation onto his own former state of health, and ascertained that when a young man he had had a severe sore throat. On examination of the fauces, marks of former syphilis could be seen. He also stated that he had suffered at the same time with cutaneous disease; that his general health was bad, and that there were pains in his bones.

This seemed to me to be a clear case of syphilis in the father; and I argued accordingly as to the case of the son, whose treatment was changed from that already ordered to an anti-syphilitic one. From this time onwards the progress of the case was good. He began to gain in flesh, his cough became less troublesome, and the expectoration decreased. The unhealthy sounds in the lungs gradually disappeared, and I got the credit of curing a consumptive.

Almost to a day, one year after the above patient consulted me, his sister came, and for the same condition—consumption—as she thought. There was not the same difficulty in the way this time. My former experience stood me in good place, and enabled me to proceed at once to a specific form of treatment. The results were, as in the former case, good.

Previously to either of these patients consulting me, a brother had died of some pulmonary condition.

I do not pretend to say why it was that three persons contracted pulmonary disease as a result of inherited syphilis. It might possibly be that there was a weakness in the respiratory organs, and it became distinctly apparent under the influence of the syphilitic virus. One thing remains, as a clear fact, that two of the three recovered from their lung disease under proper treatment for syphilis; and the third, who died, might have recovered under the same management.

The third instance of the ill-effects of inherited syphilis on the respiratory organs was afforded by the child of a man whom I treated for the disease some time before he was married. This man, though well warned of the fact that syphilis required a prolonged treatment, was not overly observant of his warnings. He married, and became the father of the child which is the subject of the present remarks. This child did not come under my notice until it was about one year old, when I was consulted on account of frequent attacks of spasmodic laryngitis. I was told that these attacks had been very frequent for some months. The usual mode of treatment was recommended. The child now passed from my observation for fully six months, when I was again sent for, and informed that the attacks still continued with as great frequency and severity as ever. Recalling the fact that the father had suffered from syphilis, the child was treated with a view to this being the cause of the croup. Potassium iodide was ordered internally, and inunctions of ung. hydrarg. externally. Shortly after this treatment was commenced the child got well, and has continued so ever since.

In this case neither father nor mother had any tendency to disease of the respiratory organs. They were neither strumous nor phthisical. As the father was a known syphilitic, and the child's spasmodic laryngitis was rapidly cured by a course of specific treatment, one can hardly but admit that the inherited taint here stood to the child's sufferings in the relation of cause and effect.

A fourth and instructive case was that of a young man who had been treated for syphilis in one of the Dublin hospitals. He was a rather intelligent person and could relate accurately the circumstances connected with the disease—its name, and the symptoms it gave rise to. This was about seven or eight years before the date on which I saw him.

At my first visit I found him suffering with asthma and bronchitis, both of which proved very obstinate. He informed me that he had been playing in a band almost every evening during the entire winter and spring up to the date when I saw him, in May.

This was his first attack of asthma, and, apart from slight colds, his first attack of bronchitis. The usual remedies for asthma had only an ameliorative effect. The bronchitis continued, despite all efforts, and he had frequent attacks of coughing, severe enough to give rise to some hæmoptysis. It was after attending him for considerable time that I learned his syphilitic history as already stated.

On making this discovery, he was ordered iodide of potassium, and from this time onwards he improved steadily. There are a certain number of cases of asthma that do well on potassium iodide, but whether all of them have a syphilitic taint or not I do not pretend to say. I have met with other cases of asthma that did not improve on the administration of this drug. The clinical facts of importance in the present case are that the patient had had syphilis, that he had been engaged in a band, and had induced bronchitis from the exposure and strain, and that no improvement took place until an antisyphilitic treatment was ordered. It seems to me absurd to deny that there was some connection between the two diseases in the above case.

The case to be mentioned next is also an example of asthma. This time, however, the syphilis was evidently hereditary. The patient was twenty-four years of age, and came to me from the country, through the recommendation of a former patient. His teeth were very characteristic of inherited syphilis. His father had suffered, as far back as my patient could remember, with scaly eruptions of the skin. There were no brothers or sisters, so that additional information from this source was impossible. The most careful investigation gave no suspicion that the young man had contracted syphilis during his lifetime, while the circumstances just mentioned regarding his teeth, and the skin disease of his father, strongly favored the belief of its hereditary nature.

One day in July, while very warm, working in the hay-field he was caught in a shower, and suffered most severely from bronchitis for about a week, when the asthmatic breathing came on. After this had existed for four months, to such an extent that he had only been able to lie in bed some two or three nights, he came to me. At this interview I gathered the above information regarding himself and his father.

During the four months previous to his consulting me, he had been variously treated for asthma, and without success. Knowing that potassium iodide was useful in some cases of asthma, and suspecting syphilitic mischief to be going on in this case, he was at once put on large doses. The result was most gratifying. At my request, he secured for me copies of the prescriptions he had been using. They contained chloral, bromide, asafœtida, lobelia, belladonna, opium, grindelia, the smoking of stramonium leaves, and the burning of nitre paper. From these remedies he derived only temporary benefit.

Here, again, we have pretty strong evidence that the asthma was in some way dependent upon the syphilitic taint. The probability is that, when the bronchial inflammation took place, the irritation from this caused the disease to become manifest in the lungs in somewhat the same way that an injury to a syphilitic may be recovered from very slowly, the tissues of the body not being in a good state of nutrition.

Another experience which set me thinking on the possible connection between inherited syphilis and phthisis came under my notice lately. One night I was sent for to attend a woman in confinement. It proved to be her fourth child. She had had no miscarriages. After the child was born, the mother began telling me the story of her misfortunes with her former children. She informed me that they had all died quite young—one three months, one five months, and the other nearly a year old. She also said that they all appeared to die in decline. They began coughing, and gradually emaciated away. I could find no special evidence of syphilis in either parent, as far as the mother could answer my questions. Her sister died in decline; but, further than this, I could trace nothing.

This child, like the others, soon began to show signs of failing health. Not knowing what to do, and being anxious to make some attempt, the mother was ordered perchloride of mercury, gr. $\frac{1}{12}$ three times a day; and the child, pot. iodidi, gr. $\frac{1}{4}$ twice a day. This was purely tentative treatment, yet it turned out to be a good experiment. The mother's own health has improved very materially. The child has done well ever since, is now between seven and eight months, and there is not the slightest appearance of its being attacked by any wasting disease.

Now, in this case, we have two or three valuable lessons to learn. In the first place, the child's aunt died of what was called consumption. There would, therefore, seem as if there was a tendency of some kind to pulmonary disease in the family on the mother's side. This tendency may have been transmitted to the children of the person I attended. In the second place, however, we have the very interesting fact that the child just mentioned recovered under antisyphilitic treatment, through the milk of the mother and directly to itself. Now, consumption is not amenable to such remedies The only conclusion then is, that, whatever the tendencies of the family may have been to phthisis, the real cause

of it in this case was some concealed syphilitic taint. In the last place, had the syphilitic condition been a little weaker, as it might have been, these children could possibly have escaped it, and developed and strengthened the tendency to phthisis; so that, in the event of their reaching maturity and having children, these latter would only show this phase of the hereditary dyscrasia. Thus, it seems to me, that the syphilitic condition gradually weakens; while the unhealthy tissue state arising out of this, and in some cases being mainly marked in the lungs, becomes the *fons et origo* phthisis. This view does not in the least clash with the doctrine of the bacillus tuberculosis. The teachings of some of our best observers, including Austin Flint, Sr., is to the effect that there must be a susceptibility to the bacilli in such persons as become consumptive. This susceptibility can come from any cause producing malnutrition, and I think that there is none more likely to cause this malnutrition of tissues than neglected syphilis.

I have now to give the history of a family that has been under my notice for more than three years, and during this period I have had a great deal to do with the children, four boys in all. These boys ranged in age from eighteen months to seven years at the time I commenced attending them. I do not think I ever knew a family of children more subject to bronchitis than these boys. From time to time they would take fresh attacks, and it was an exceptional occurrence to find them all free at any one time. Their attacks were of a somewhat mild, yet chronic character.

Neither the father nor the mother of these children was liable to colds or coughs. The father's brother had died of consumption, and the mother's father of pneumonia. With these two exceptions, the family record was good on both sides, as far as any form of pulmonary disease was concerned.

After I had been attending the family for about two years, the father asked me one day if syphilis could be completely removed from the system. From this, as a starting-point, we had a lengthy talk upon this disease, during which he admitted that he had had it many years before he was married, and that he had taken medicine for a year, though not very regularly.

On my finding this out, the children were treated with mercury and iodides, and with the very best of results. They soon recovered from their tendency to contract bronchitis, and improved in general appearance. The mother said to me one day that the last medicine was what did it, as they all got well after it was ordered.

One more remark in conclusion. I strongly believe that the low state of health which often leads up to consumption is, in not a few cases, due to inherited syphilis. This is the blighting cause that undermines the general condition of body nutrition, which so often precedes phthisis. The late Dr. Gross taught that scrofulosis was often a run-out syphilis, or this taint became weakened by passing through several generations. Just so I think with a certain percentage of tubercular cases.

The proportion of consumptive cases that are due to syphilis, I cannot in the least say, as my statistics are not sufficiently extended. This would require a long series of cases, and much time. Nor do I know the percentage of those chronic lung diseases, due to syphilis, that would yield to specific treatment. There is no doubt of the fact that many such cases, like syphilitic lesions elsewhere, would recover; while, at the same time others would not. For example, where the syphilitic taint is remote, it might so act as to produce only a predisposition; and the phthisis, being excited into existence by such conditions as we know to give rise to it, might be incurable The more recent the syphilis, the more likely would treatment, directed toward it, be successful in arresting pulmonary disease that might have arisen from it. On the other hand, the syphilitic taint coming from a grandparent would show itself in little else than a mere cachexia. On this cachexia, true tuberculosis or other chronic lung disease being implanted, the prospects of treatment would be very much less promising, as it would approach more nearly a case of phthisis, and less one of syphilis.

MEDICAL PROGRESS.

RESECTION OF RIBS FOR PYOPERICARDIUM.—At a late meeting of the Verein Deutsch. Aerzte in Prag, PROF. GUSSENBAUER exhibited a boy, 13 years old, in whom he had evacuated by thoracotomy the fluid of a pyopericarditis accompanying an acute osteomyelitis. The operation was successful, and the boy entirely recovered. The osteomyelitis resulted from a fall upon the right shoulder, which was followed by local pain and high fever, with great swelling of the shoulder and adjacent parts. A diagnosis of osteomyelitis was shortly made; and on the 3d of May, fourteen days after the accident, the boy was operated upon. An incision at the infraspinous fossa was made, and was followed by the escape of pus, and the bone presented a grayish appearance. The operation was done with antiseptic precautions. The temperature did not fall as expected, but rose, without any apparent cause.

On the 20th of May, fluid was discovered in the left thorax, the heart was not noticeably displaced, and the intercostal spaces not obliterated. At first, a left-sided pleurisy was suspected, and an exploratory puncture showed a puriform exudation. The patient at last becoming cyanotic, an operation was decided upon, and five ribs were resected. It was then noticed that the intrathoracic fascia was not thickened, and further examination showed the effusion to be pericardial. The pericardium was then fixed to the edges of the wound to prevent escape of the fluid, on its evacuation, into the pleural cavity. During the operation, the heart could be seen, and felt palpitating. The pericardium, after the withdrawal of the purulent contents, was washed out with a thymol solution. The following day, there was marked improvement, the temperature fell at once, and complete restoration soon followed.—*Wien. med. Wochenschr.*, Nov. 21, 1884.

EXPERIMENTAL THYROIDECTOMY.—Whilst the subject of the relations of the thyroid gland to myxœdema and allied affections is attracting so much attention both at home and abroad, it will be useful to give an abstract of the results of a series of experiment per-

formed by Schiff, who is one of the foremost workers in this field of inquiry. All the animals from which the thyroid gland had been removed died within from four to twenty-seven days after the operation; and those animals that survived more than sixteen days died after the wound had completely healed. Somnolence and indifference, slowness and hesitation of volitional movements, fibrillar contractions of the muscles, alteration of the respiratory rhythm (so-called *respiration cardiaque*), sensations of itching of the skin, and diminution or disappearance of tactile sensation, were the chief phenomena observed. The excitable area of the brain did not react to the most powerful galvanic stimulation. As death approached, the arterial blood-pressure underwent an extraordinary fall, owing to the dilatation of bloodvessels. The muscular tremors disappeared on section of the motor nerves supplying the affected muscles. The symptoms observed in different animals varied considerably. Schiff has concluded that the thyroid gland exercises a great influence over the nutrition of the central nervous system.—*Lancet*, Dec. 13, 1884.

Hydrocele in Women.—Hennig, in *Centralbl. f. Gyn.*, October, 1884, remarks that hydrocele in women is a rare disease, and that but thirty-nine cases have been reported. It is observed at all ages, but most frequently in women who have borne children. Ordinarily, it exists without pain. At first the tumor is small, and disappears upon lying down. Scarcely any fever is produced, except when the tumor is inflamed.

The treatment consists in reducing the tumor, and maintaining the reduction by a bandage till the canal is closed by adhesion. In two cases, cure was obtained by simple puncture; in another, by injection of iodine. Good results were obtained also by passing an iron wire through the tumor, and tightening it till the walls are in apposition.

Treatment of Urticaria by Jaborandi.—M. Guéneau de Mussy has treated urticaria in arthritic subjects successfully with jaborandi. The mode of administration was: powder of jaborandi, extract of guaiac, āā gr. iss, benzoate of lithia three grs., in one pill. Two pills were at first given in twenty-four hours, and the number increased to four. The treatment was continued many months. Improvement was prompt.—*Revue de Thérapeutique*, Dec. 15, 1884.

Modification of Schede's Empyema Operation.—Dr. Otto Sprengel reports (*Archiv für klin. Chir.*, Bd. xxx. S. 618) the following modification of Schede's operation for empyema. (It will be remembered that Schede resects a piece from the thoracic wall, making a trough-shaped opening through which the pleural cavity may be washed out.) Sprengel resects two ribs to the extent of several centimetres, scrapes out and disinfects the pleural cavity, and tampons it with an antiseptic dressing until the cavity is filled by granulations, and is thus soon contracted.—*Centralbl. f. d. med Wissensch.*, Oct. 25, 1884.

Lesions of the Nervous System Etiologically Related to Cutaneous Disease.—Dr. H. Radcliffe Crocker, in a learned article on this subject, which appears in the October number of *Brain*, deduces the following conclusions:

That less serious consequences ensue from cutting off the nervous supply than from irritant or inflammatory lesions of the parts of the nervous system that affect the skin.

That the kind of eruption produced by the nervous system varies greatly, often without any evident reason, when the nervous defect is apparently the same in place and kind.

That the same eruption may owe its origin to any defective link in the nervous chain from the centre to the periphery.

That the same kind of nervous lesion that at one time appears to excite an eruption or other nutritive defect in the skin, even more frequently produces no change in the skin whatever.

The lesions other than atrophy that result when innervation is abolished are often traceable to external injurious influences which the tissues, when unprotected by the nervous system, are unable to resist; but we know nothing of the conditions that determine the nature of the eruption or other skin defect when the nerve lesion is irritative, nor what it is that determines whether there shall be any eruption, or none at all. This uncertainty of effect suggests that the nervous influence is an indirect one.

The cerebral effect appears to vary according to whether its control over the vaso-motor centre is increased or decreased and to the secondary changes it induces in the cord. No localizing lesions have yet been found for its influence on the vaso-motor centre.

In the spinal cord the fibres that preside over the nutrition of the skin are bound up with the sensory fibres, and reside, therefore, mainly in the posterior columns.

That outside the cord the path is by the posterior roots, the spinal ganglia, and the sensory fibres, and that lesions of any one or more of these may lead to changes in the skin.

The Comma-bacillus of Cholera.—In the stools of nine cases, examined during the recent epidemic, M. Babès found, in the mucous membrane of the ileum, comma-bacilli in nearly all, and cultivated them according to Koch's method slightly modified. Instead of agitating the fecal matter taken from the intestine with gelatine, liquefied by heat, he began by agitating it with sterilized distilled water, and then cultivated a drop of this water upon a plaque of gelatine. This method can be advantageously combined with that indicated by Koch.

M. Babès sought without success for the comma-bacillus in other organs than the intestine. However, in one case, he cultivated a tube containing a portion of the kidney taken from a cholera patient, and obtained the comma-bacillus. As this case is unique, and is not confirmed by other experiments, he suspects it was due to some oversight, and believes it does not invalidate the results of former experiments.—*Le Progrès Medicale*, December 6, 1884.

The New Operations for Cæsarean Section.—In an interesting paper in the *Deutsche med. Wochensch.*, December 18, 1884, Volkmann reviews the different

operations for Cæsarean section, and makes the following practical suggestions as to the method to be selected:

1. The old method of Cæsarean section, whether upon the dying or dead woman, must be performed according to the established principles, when the end to be attained is the speedy delivery of the child.

2. Cæsarean section with the peritoneum included in the suture (the modified Sänger's method) should be performed according to the relative indications—*i. e.*, if the woman does not wish to be deprived of the power to conceive, or, if it is called for, in cases of deformity, carcinoma of the cervix, etc.

3. Porro's operation is recommended in all cases of osteomalacia, and marked contraction of the pelvis, and also when a second operation would be required should pregnancy again occur. It is also required in cases of incurable tumors.

Muslin Ointments in the Treatment of Diseases of the Skin.—In an instructive article in the *British Medical Journal* for December 20, 1884, on certain new methods in the treatment of diseases of the skin, Dr. George Thin maintains that there is no doubt that the unsatisfactory results of much of the treatment of eczema by ointments is due to the difficulty which is experienced in getting the affected skin well covered with the unctuous application which is prescribed. To overcome this difficulty, Unna conceived the idea of incorporating stout unstarched muslin with a thick layer of ointment. As a basis for the ointment, mutton-fat seemed to him to be the most useful. This muslin ointment, when closely applied and bound on the skin, secures, in Unna's words, "absolute rest to the integument, prevents rubbing by clothes, and excludes the atmospheric air." These muslin ointments are prepared spread on one or both sides of the muslin, and consist of a large variety—amongst them being representatives of nearly all the ointments that are in use in the treatment of skin diseases. To their great utility, Dr. Thin strongly testifies.

As, so far as he knows, muslin ointments are at present only made in Hamburg, and patients cannot get them without incurring delay and trouble, he has not prescribed them in many cases in which he should have otherwise done so. In cases, however, in which the expected benefit from ordinary ointments was not derived, he has found the muslin ointments, supplied by Beiersdorf, successful. For example, in the case of a young boy who was afflicted with frequent outbreaks of papular and pustular eczema over large portions of the body, necessitating the frequent use of soothing ointments, the difficulty of keeping zinc ointment properly in contact with so large an extent of surface, in the active and restless patient, was found to be a great drawback, and the result of the treatment was consequently unsatisfactory. He thought of Beiersdorf's muslin-zinc-ointment, and its application was not only found simple and convenient by his nurse, but healed the eczematous eruption much more rapidly than had been the case when ordinary zinc ointment had been applied in the usual way. This better result was no doubt due simply to the fact that the muslin ointment afforded a more complete covering to the skin than zinc ointment did when it was spread on lint or linen by the nurse. The physical consistence of these muslin ointments surpasses in applicability that of any ointment spread for the occasion on cloth.

The Application of Cocaine to Diseases of the Ear and Nose.—Prof. Zaufal, at a late meeting of the Verein Deutscher Aerzte, in Prag, reported the results which he had obtained from the use of three and five per cent. solutions of cocaine for anæsthetic purposes. Applied to the walls of the nose, it exercises a prompt anæsthetic effect.

In chronic nasal catarrh, he was able to operate with the galvano-cautery without pain to the patient. In the application of cocaine to adenoid vegetations of the nasopharyngeal cavity, favorable results are also anticipated, and likewise for the anæsthesia of the external auditory canal. It was observed that the epidermis and underlying adipose tissue of the canal impeded the action of the cocaine. True anæsthesia of the tympanic membrane was produced, and in two cases granulations of the middle ear were removed without pain.

Prof. Ganghofner reported success with a fifteen to twenty per cent. solution of cocaine in intralaryngeal spasm.

Prof. Kahler likewise obtained from its use good results in a hysterical woman suffering with vomiting of pregnancy.—*Wiener Med. Presse*, Nov. 30, 1884.

Resorcine in Intermittent Fevers.—In an elaborate memoir upon this drug, Dr. Vittorio Gasparetti presents the following conclusions:

In twenty-five cases of intermittent fever of various types, twenty-three were cured, and two benefited. It does not always at once prevent the attacks, but in a short time they cease to appear under its administration. The spleen does not appear to be affected by the drug. Disturbances of innervation, which sometimes occur, are rare, except in toxic doses. In these cases, no bad effects worthy of notice were observed.

Resorcine is eliminated by the kidneys, but does not disturb their function. Its beneficial action is more pronounced in the quotidian and tertian types, less decided in the quartan. In this form, it frequently fails to produce results. It satisfactorily replaces quinia in action, cost, and taste, and is very acceptable to children, and is valuable as an anti-ferment in catarrh of the digestive tract. Its average per cent. of cures is greater than that of any other antiperiodic. Its action is very prompt, owing to its rapid absorption.

Gilberti observed that a single dose which reduced the temperature 3.7° F., when given in divided doses at intervals of ten or fifteen minutes, produced changes of only a few tenths of a degree. The dose for an adult is thirty grains in an ounce of water, to be taken in divided doses in one hour, and about an hour previous to the time the fever is expected. A large, is no more efficacious than a moderate dose. Whether the hæmoglobin is increased by its use has not yet been determined.—*Gazetta Medica di Torino*, Dec. 15, 1884.

Diagnosis of Gastric Disease.—Methods have been adopted from time to time with a view of determining the digestive activity of the gastric juice outside the body. Van der Velden elaborated a method for carrying out this plan by getting patients to swallow a dry sponge enveloped in a gelatinized capsule. Leube used

to wash out the stomach with about 300 cubic centimetres of iced water. Recently M. Beaumetz has adopted the principle of aspiration in order to obtain some gastric juice. There appears to be no need for the practical physician to acquaint himself with the details of the procedure nor with the minutiæ of the apparatus concerned. Van der Velden said that in cancer of the stomach the secretion from this organ contained no hydrochloric acid, and thus believed that an easy way was open for us to distinguish between cancer and other chronic gastric disorders. Leube concluded that the degree of acidity of the gastric juice would give us some idea of the degree of the dyspepsia, and he drew no other conclusion from his careful study of the subject. A certain coloring matter derived from coal tar, and known as orange-poirier No. 4 or tropeoline, undergoes a change to a clear violet-red tint when a one per cent. solution is brought in contact with muriatic acid, whilst it does not lose the yellow tint with lactic and other acids. This tropeoline has been employed in testing the condition of the gastric juice. The above information is interesting, but as yet cannot be said to possess any value for clinical medicine.—*Lancet*, December 13, 1884.

NEW INTERPRETATION OF THE MENSTRUAL PROCESS.—LOEWENTHAL, in an article upon this subject which appears in the *Arch. f. Gyn.*, xxiv., 1884, cites the different opinions of authors upon the relations which exist between ovulation and the menstrual flux, and gives a complete résumé of our knowledge on this subject.

According to Loewenthal, the periodic flow occurring in menstruation is not due to the rupture of the Graafian follicle, although the two phenomena, for the most part, coincide. The hemorrhage is due to an elimination from, or contraction of, the mucous membrane, which at this period is considerably thickened. This menstrual change is caused by the presence of an ovule previously expelled from the ovary.

If the ovule is fecundated, the changes result in phenomena of the sickness of pregnancy. Coincidence between the rupture of the follicle and the menstrual flow does not necessarily exist. They may be separately produced, the rupture of a follicle taking place without change in the uterine mucous membrane and flow of blood. The periodicity of the appearance of the menses is in relation with the non-fecundated ovum lodged in the uterine mucous membrane. The differences observed in this periodicity are due to various causes, specific or general, which influence the vitality of the ovum.

Fecundation usually takes place in the uterus, rarely elsewhere. A fecundated ovum is expelled from the ovary, usually soon after a menstrual period.—*Gazette Médical de Paris*, Dec. 20, 1884.

A CASE OF VAGINISMUS TREATED WITH HYDROCHLORATE OF COCAINE.—DUJARDIN BEAUMETZ reports, in the *Bull. Gén. de Thérap.*, Dec. 15, 1884, a case of vaginismus treated with hydrochlorate of cocaine with good effect. The patient was married, and showed no signs of hysteria. At first during conjugal intercourse no pain was experienced. Some years subsequently she gave birth to a child after tedious labor. A few months after convalescence sexual intercourse became extremely painful, and for two years was impossible. Examination revealed the fact that extreme pain resulted from digital touch, and a contractile band within the vagina resisted the introduction of the finger. Forcible dilatation under chloroform failed to produce good results, as likewise did mild dilatation by the bivalve speculum. Finally hydrochlorate of cocaine was applied in two per cent. solution to the labia minora and orifice of the vagina. Within a minute sensibility disappeared, and the speculum was introduced without pain.

Two days subsequently the speculum was introduced without previous application of the cocaine, and produced but slight pain. After four applications of the anæsthetic, pain on introducing the speculum was almost entirely absent, and the band which constricted the vagina had disappeared.

BEAUMETZ pronounces, as the result of numerous observations, cocaine hydrochlorate to be also the best therapeutic agent in vaginismus due to inflammation and ulceration of the vulvar orifice.

OPERATIVE TREATMENT OF PRURITUS VULVÆ.—SCHRÖDER maintains that in cases of pruritus vulvæ which have long resisted treatment, operative interference is necessary, and in the cases which he cites benefit has never failed to result from it. The condition which indicates the operation is—pruritus upon circumscribed, contracted spots, which project above the level of the skin, and are of a whitish color. The operation consists in excising the tissues as far as the diseased condition extends and bringing the sound parts into apposition. This procedure is rarely required, four cases only having so far been met.

In a condition analogous to that already described, existing in unmarried women, there was a remarkable degeneration of the skin surrounding the anus, simulating but not identical with pruritus. In this case an annular excision of the skin around the whole circumference of the anus was made. It was at first thought a cure had been effected, but later the disease returned. —*Centralbl. für Gynakol.*, Dec. 13, 1884.

BACTERIA IN ULCERATIVE ENDOCARDITIS.—M. CORNIL, in the *Journ. des Connaiss. Méd.*, Dec. 22, 1884, discussing the origin of these bacteria, holds that in the various febrile diseases, puerperal fever, pyæmia, septicæmia, and in traumatic inflammations, the lymphatic cells or white blood-corpuscles contain these bacteria under the form of cocci, isolated or in chains. These cells are carried in the blood current throughout the system and are deposited at various points, among which are the valves of the heart, which, by reason of their alternate contraction and relaxation, are favorite seats of deposit. Thus ulcerative endocarditis is produced in erysipelas and pneumonia.

Koster, however, believes that the microbes reach the valves through their nutrient capillaries.

In the opinion of Cornil, this view is untenable, inasmuch as the bacilli are found only on the surface, not in the tissue of the valves, which would be the result if they were deposited by the nutrient capillary vessels.—*L'Abeille Médical*, Dec. 22, 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JANUARY 17, 1885.

IS TUBERCULOSIS PRODUCED BY THE INOCULATION OF INDIFFERENT SUBSTANCES?

THE publication in 1866 of the results of Villeman's experiments upon the inoculation of tuberculosis, was soon followed by the enunciation of the doctrine that tubercle can also be produced by the inoculation of indifferent substances, such as inspissated pus, dried blood, fragments of cheese, particles of glass—in fact, indifferent substances of any kind. The supporters of this doctrine included at one time some of the most authoritative names in pathology, notably Cohnheim, Waldenburg, Burdon-Sanderson, and Wilson Fox. Cohnheim was the first to leave the ranks. In repeating his experiments, he arrived at different results, and concluded that tubercle could only be produced by the inoculation of true tubercle. The change of view of such a well-known and skilful experimenter naturally carried with it many who were satisfied to pin their faith upon his opinion. Then followed the very careful experiments of Koch, who insisted that not only must the material be tubercular, but that the inoculation to be successful must contain the tubercle bacillus. These researches caused Wilson Fox to repeat his experiments, and the negative results he obtained led him also to renounce his original views. Thus another strong prop was withdrawn.

We have more than once called attention to the importance of this question as bearing upon the infectious nature of tuberculosis, and especially its origin in a fungus. Granted that indifferent substances, like powdered glass and ultramarine blue, may produce tuberculosis by their inoculation, the bacillus tuberculosis may be classified among such substances, and produce the disease in the same manner. If, on the other hand, it be shown that the inoculation of indifferent material is incapable of producing tuberculosis, the only remaining obstacle to the acceptance of the parasitic origin of tubercular phthisis is removed.

The announcement, therefore, of the results of the carefully conducted experiments of DR. STERNBERG, in *The American Journal of the Medical Sciences* for January, 1885, is an important one in this connection. The experiments consisted in the injection of ultramarine blue into the peritoneal cavities of two rabbits, and of powdered glass into those of two others. The injections were made in the laboratory of the Johns Hopkins University at Baltimore, with material furnished by Dr. Formad, of Philadelphia, who was present, and who determined also the quantities to be used. In the afternoon of the same day, in the country eight miles from Baltimore, eight more rabbits were similarly injected, four with blue and four with glass The rabbits operated upon in the city were placed in an apartment adjoining another in which were rabbits inoculated with sputum containing the tubercle bacillus, the object being to test the question whether association with tubercular animals would make a difference in the result.

One of the four rabbits operated upon at the laboratory was evidently in poor health, and died the next day. Another died four days later, probably from injury to the intestine during the operation. Another of the laboratory rabbits died twenty-eight days later, and at the autopsy Dr. Councilman found the blue pigment, in large quantity, in the cavity of the abdomen, free and encapsuled, and in the lymphatic vessels of the diaphragm in such quantity as to give them the appearance of having been artificially injected. One rabbit injected with the blue died in the country nine days after the operation, and one injected with glass thirty-six days after being operated on. Of the remainder, two were killed forty-one days after being operated upon, one having been injected with the blue pigment, and one with glass. Neither of these presented any evidences of tuberculosis, and the others were allowed to live a month longer.

All the animals were examined after death by Dr. Councilman, of Baltimore, who found that the pathological changes differed somewhat in those injected with blue and in those injected with glass, the evidences of local inflammation being more decided and adhesions more numerous in the latter. Numerous nodules were found in both, varying in size from the head of a pin to that of a bean, being pigmented in the case of the blue, and pure white in that of the glass. They were found upon the peritoneal surface and on the liver. The nodules in the case of the glass injections most closely resembled tubercles.

They were of a whitish color, and on section a soft mass could be squeezed out of them which could be easily crushed between the fingers, and on a superficial microscopic examination might have been taken for a caseous mass. But more careful microscopic examination set all doubts at rest. The large nodules were composed of masses of glass enclosed in vascular connective tissue, which also penetrated between the glass, dividing it into small areas. The smaller nodules were found where only a small amount of glass was present. But a few cells were found commingled with the glass, and sometimes a slight nuclear increase was found around one or two bits of glass, at others the glass was enclosed in a small mass of connective tissue very rich in cells. At no place was any glass taken up in the tissue or lymphatics, in striking contrast to what was found where the blue injection was used. In no instance was any true caseation found, and there were no nodules which had even the anatomical structure of tubercles—the so-called pseudo-tubercles.

The rabbits which had been injected with tuberculous sputum in the course of the experiments, were examined, and typical tuberculosis was found to have been produced in two. There was a large caseous mass at the point of injection, the axillary glands were caseous, and there were innumerable caseous nodules on the lungs, liver, and elsewhere. In one there was no caseation at the point of injection, nor were the lymphatic glands affected, but the lungs contained numerous grayish, transparent nodules, some single and some conglomerate. Tubercle bacilli were found in every instance, in the nodules in the internal organs, the caseous mass at the point of injection, and in the cheesy lymphatic glands.

These observations appear to us the most important yet published in this country, and go a great way towards confirming Koch's doctrine.

Dr. Sternberg also published in the same article a letter from Dr. James E. Reeves, of Wheeling, W. Va., describing the clinical history and macroscopic post-mortem appearances in the so-called "nailers' consumption." In consequence of the late date at which Dr. Reeves's letter was received it was impossible for Dr. Sternberg to give the subject much consideration, but we hope he has not dismissed it finally with the statement that it "is evidently not tubercular." For although Dr. Sternberg's experiments tend to weaken much the grounds of the belief which has been very general until lately, at least, that "nailers' consumption" is a variety of phthisis pulmonalis, they do unquestionably present a clinical history which is that of many cases of true tubercular phthisis, and the importance of the subject demands a closer minute investigation. It is true that Dr. Reeves, who is very successful in demonstrating tubercle bacilli, failed to find any in the sputum of a large number of these cases which he examined, but to say that they are not tubercular for this reason is, as yet, begging the question. There were fibrous (?) nodules, dilated bronchi, and enlarged glands which should be carefully studied before a conclusion is reached. "Now and then," says Dr. Reeves, "a case is met with in which the lungs are the seat of tuberculosis; but in such instances, I doubt not, the family history, if questioned, will show tuberculous tendency."

This class of cases, including the phthisis of grindstone workers, steel grinders, file makers, and miners, has not yet been thoroughly studied. Science is exacting, and many still believe these forms to be tubercular, and will continue so to believe, until exact methods are brought to bear to remove all grounds of such belief.

EXTIRPATION OF THE BLADDER FOR SARCOMA.

DURING the past two years several papers have appeared in the German medical journals in which, through experiments upon dogs, it was shown that the urinary bladder might be successfully removed. As the natural sequence of these vivisections, we have now to record the extension of the operation to the human subject by SONNENBURG, of Berlin, which is fully described in the *Berliner klinische Wochenschrift*, No. 52, 1884.

The patient was a woman, 60 years of age, on the anterior wall of whose bladder digital exploration disclosed what appeared to be a circumscribed, non-ulcerated carcinoma. As the suffering was great, and as she was losing much blood, it was determined to remove the tumor along with the adjacent tissues of the bladder, and close the wound with sutures. The organ having been opened as in epicystotomy, it was discovered that the limits of the neoplasm were not sharply circumscribed, so that for its complete removal the entire viscus, except a small portion of its posterior wall, the trigone with the openings of the ureters, and the sphincter, was excised. During the operation the peritoneal cavity was freely opened, but the edges of the wound in that membrane were carefully brought together with sutures. Drainage-tubes were brought through the urethra and the abdominal incision, thereby providing for the thorough escape of the urine and the secretions of the wound, and, at the expiration of three weeks, the patient was progressing satisfactorily, the wound was granulating nicely, and there was every prospect of ultimate recovery.

The case thus briefly recorded shows that the greater portion of the urinary bladder may be extirpated with a fair prospect of temporary success. In view, however, of the probable recurrence of the disease, and of the immediate risks to which the aged patient was subjected, we cannot congratulate

the operator upon his daring performance—a performance which may, in the opinion of some surgeons, redound to his credit, but which we regard as being utterly unjustifiable. There is a limit to operative procedures in malignant disease, and surely the limit was reached in this case, the infiltration of the walls of the bladder having progressed to an extent which should have suggested the establishment of a vesico-vaginal fistula, to provide for the free escape of urine, and thereby to do away with the periodical filling and emptying of the bladder, rather than the harsh procedure to which Sonnenburg resorted. Colpocystotomy and the formation of a permanent fistule would certainly have mitigated the suffering and arrested, partially, at least, the bleeding. To fulfil these indications should have been the aim of operative interference; to have extirpated nearly the entire bladder was as useless as it was unsurgical.

REMOVAL OF A BRAIN TUMOR.

FERRIER'S forecast, made about a year ago, that the doctrine of cerebral localization would in the future have an extensive surgical application, has been fulfilled in a recent case at the Hospital for Epilepsy and Paralysis, London. A man, aged 25, consulted Dr. Hughes Bennett for paralysis of the left arm. Four years previous he had received a blow on the left side of the head. A year after, twitching began in the tongue and left side of the face, which soon became worse, occurred paroxysmally, and he had "fits," general convulsions, and loss of consciousness. Ultimately, the arm became quite useless for finger and wrist movements; the left leg also began to get weak. There was double optic neuritis. A diagnosis was made of tumor of the cortex involving the centre of the hand, and irritating the face and leg centres. Dr. Bennett suggested its removal. On November 15th this was done by Mr. Godlee, of University College, who trephined over the upper part of the fissure of Rolando. When the cortex was exposed, no tumor could be seen, but the ascending frontal convolution was distended. An incision was made into it, and at a quarter of an inch below the surface a hard glioma the size of a walnut was found and removed. Twenty days after the operation the condition of the patient was most satisfactory; the vomiting, pains, and convulsions had ceased, but there was a tendency to hernia of the brain substance and paresis of the leg had increased. On the morning of December 16, more unfavorable symptoms set in, rigor, fever, sickness, and pain in the head, and the hernia of brain-substance increased. He gradually sank and died on the 23d, consciousness remaining until the end. The post-mortem showed death to have been due to meningitis.

It is a matter for general regret that this case, in which medical and surgical skill were so conspicuously displayed, did not reach a successful termination. Still, we should not be discouraged. It illustrates, however, the dangers of cerebral surgery in man, and shows the difference between the Simian and human brain as regards the freedom from reaction after operative measures. Ferrier and others speak of "the unfailing safety, the freedom from all untoward results," in the case of the former, but there are grave risks to be incurred in the latter. If success is to be obtained, it is just in these cases of Jacksonian epilepsy that we may expect good results, for the localization can be made with tolerable accuracy, and the lesions are often limited. The case reported by Dr. Osler in the January number of the *American Journal of the Medical Sciences*, of cortical epilepsy of twelve years' duration, due to a small glioma not larger than an almond, is an instance in which an operation would have been justifiable and possibly have been the means of saving life.

PULMONARY SYPHILIS.

IF we are to credit the clinical reports, syphilis of the lungs is a tolerably common affection; on the other hand, in the post-mortem room it is among the rarest of anatomical lesions, so much so, indeed, that men of large experience have seen but one or two specimens. There is a well-recognized syphilitic pneumonia in the new-born, and in the adult, gummata of large size have been found; but with the exception of these two conditions our knowledge of pulmonary syphilis is extremely limited. Areas of fibroid induration about the hilus or beneath the pleura are supposed by many to be syphilitic, and may be in some cases, but they occur also in persons without any specific taint. Grandidier states that the affection is most common in the middle lobe of the right lung; Pancritus, that the parts about the hilus are most often involved. The process is confined to the interstitial tissue, and is at first a small-celled growth, which is gradually converted into fibrous tissue and a form of cirrhosis is induced. Caseation may occur with softening and the production of syphilitic phthisis. It does seem probable that some of the cases of cirrhosis of the lung have a syphilitic origin.

What now is the clinical evidence upon which a diagnosis of lung syphilis is usually based? First, the existence of the acquired or inherited disease. This is all important. Second, the beneficial effect of mercury and iodide of potassium. The history and the treatment are deemed sufficient as in the series of cases reported elsewhere in this issue. The history even may be very imperfect; thus as the ten

cases of pulmonary trouble due to inherited syphilis there given, in only one is it stated that there were other signs of the disease such as we can often discover in these subjects, leaving us to conclude that in nine the lungs were alone attacked; that is to say, such an extremely rare tertiary manifestation as pulmonary syphilis occurred in nine instances without, so far as we know from the records, any previous specific symptoms.

The form of cirrhosis of the lung due to syphilis has certain clinical features of some distinctness. Thus, the fever is slight or absent, the central part of the lung, particularly the middle lobe in the right, is most often attacked, and there may be irregular areas of percussion dulness. The cough is usually dry, the sputum small in amount, often bloody, and the specific tubercle bacilli are absent. These cases generally come under observation when antisyphilitic measures are useless for curative purposes.

A possible important diagnostic sign may be afforded in the discovery by Lustgarten, of bacilli peculiar to syphilitic lesions, and following close upon the announcement of this discovery Kœniger, in *Deutsche medicinische Wochenschrift*, narrates briefly six cases of chronic phthisis in which there were no tubercle bacilli, but peculiar forms resembling somewhat those of Lustgarten. In four of these cases there was a well-marked history of syphilis. We may possibly have here a means whereby syphilitic lung affections can be accurately diagnosticated; if so, it will be a great boon. At present the cases are distributed in a curiously irregular way among practitioners, some having had a great number (Pancritus, of Berlin, for example, who had over one hundred cases), others rarely having seen an instance in a long experience, a fact which, taken in connection with the *post hoc* therapeutical deductions, so important an element in the diagnosis, should make us particularly careful in our estimation of reports of pulmonary syphilis.

IS WOMAN WOMB-MAN?

Van Helmont is to be credited with the statement: *Propter solum uterum mulier est quod est.* But really he simply threw into a different form an axiom of Hippocrates. The progress of knowledge as to the physiology of the female sexual organs destroyed the force of his assertion as well as that of the axiom of Hippocrates. Chereau, writing in 1844, observed that in place of describing the ovaries and oviducts as appendages of the womb, it is more rational and more philosophic to say that this last viscus is added or annexed to the ovaries or oviducts. Somewhat less than a score of years later, Tilt, probably taking the motto from Chereau, said, "*Propter ovaria sola mulier est quod est.*"

So much for the first statements as to the relative importance, as held at different times, of the organs referred to. But was there a time when our language sought to express in the name given the human female the supposed predominance in her nature of the uterus—in a word, is woman womb-man? This suggestion of the origin of the word woman is quite fanciful and altogether modern. Let any one of critical mind turn to the Wiclif version of the New Testament, 1380, and read that part of the parable of the Prodigal Son where the King James version states "he would fain have filled his belly with the husks the swine did eat," and he will find "his wombe" is used for "his belly." Here was a womb-man, but no one can suppose he was a woman. Womb, or wombe, was used at first for belly, and not for a sexual organ peculiar to the female, while at the same period the word woman was already in use.

To our statement of the incorrect derivation of the word woman from womb, we add the following note as to the true origin of this word from one of the most distinguished and learned philologists in our country, Prof. March, of Easton, Pa.:

"*Woman* is an Anglo-Saxon *wif-man*, like German *weibs-mensch*, Latin *femina-homo*, *wif*-wife, being in Anglo-Saxon, a general word for female, and in this compound a sign of gender, in contrast with *waepen*, membrum virile, whence Anglo-Saxon *waep-man*, Latin *mas-homo; wifman* and *wepman*, for *woman* and *man* were in use almost to Chaucer's time; *wifman* changed to *wimman*, then to *wumman; woman* is a comparatively modern spelling, disguising both the etymology and pronunciation, as so much of our beloved modern spelling does."

FATTY INJECTIONS IN SALIVARY FISTULA.

In the *Abeille Médicale*, No. 51, 1884, M. Mollière, of Lyons, reports a case of salivary fistula cured by a novel procedure.

At the age of six years, when suffering from measles, a painful swelling appeared beneath the ear of a girl, which was incised, and gave vent to saliva, the flow being increased during mastication and by stimulating articles of food. Ten years subsequently, an unsuccessful attempt was made to close the opening by a plastic operation; and, a year later, when the patient came under the charge of Mollière, there was a small opening below and in front of the lobule of the ear, which communicated with a small duct given off by one of the lobules of the parotid gland.

Acting upon an experiment of Claude Bernard, who succeeded in destroying the secretory elements of the pancreas by injecting an oleaginous substance into the canal of Wirsungius, Mollière threw into the fistula about eight drops of carbolized oil, with-

out any apparent effect. Upon repeating the operation, however, six weeks subsequently, the affected lobule atrophied, and the fistula closed spontaneously.

As the parotid gland is not essential to life, Molliére recommends a resort to fatty injections in all cases of salivary fistulæ of the duct of Steno which have proved rebellious to other measures.

SOCIETY PROCEEDINGS.

PHILADELPHIA NEUROLOGICAL SOCIETY.

Stated Meeting, December 22, 1884.

THE VICE-PRESIDENT, CHARLES K. MILLS, M.D., IN THE CHAIR.

DR. MILLS read some

NOTES ON THE TREATMENT OF EPILEPSY.

His remarks applied chiefly to the medicinal treatment of epilepsy proper—grand mal, and petit mal. He did not intend to refer to the treatment of convulsive seizures due to tumors, meningitis, spinal disease, etc.

As to the curability of epilepsy, some apparently authentic cases of cure are on record. After looking over the subject, he could only recall seven cases of apparent or real cure in his own practice, private and hospital. In all of these the attacks remained away for from more than one to more than three years. Gowers mentions a number of cures, cases, at least, in which seizures had not recurred for as much as four, five, six, or seven years. Several of these cases were children. Three of the seven cases alluded to by Dr. Mills were children. All observations as to the cure of epilepsy were necessarily imperfect. After a number of years the attacks recur again. Although, however, the absolute curability of epilepsy might be doubtful, certainly great benefit from treatment is to be derived in most cases. It is a wrong to such patients not to treat them.

He had used the following remedies, singly, three or four times daily, in a series of cases, during the last ten years: Bromide of potassium, grs. x to ʒj; bromide of sodium, grs. x to ʒj; bromide of ammonium, grs. x to ʒss; monobromide of camphor, grs. iij to vj; hydrobromic acid, fʒss to fʒss; iodide of potassium, grs. v to ʒss; biborate of sodium, grs. xv to xx; chloral hydrate, grs. x to xv; oxide of zinc and valerianate of zinc, grs. iij to x; nitrate of silver, gr. ¼ to gr. ½; tincture of belladonna, ♏x to xv, or extract of belladonna, gr. ¼ to gr. ½; extract of cannabis indica, gr. ⅛ to gr. ¼; fluid extract of cocculus indicus, ♏j to iij, or tincture of cocculus indicus, ♏v to x; nitrate of potassium, grs. v to viij. Other remedies which he has only used in combination with some of the above drugs, are as follows: Conium juice, fʒj, or fluid extract, ♏iij to x; tincture of digitalis, ♏v to x; sulphate of strychnia, gr. $\frac{1}{40}$ to $\frac{1}{30}$; Fowler's solution of arsenic, ♏ij to v; fluid extract of ergot, fʒj to fʒij, or extract of ergot (Squibb's), grs. iij to vj; iron, cod-liver oil, and quinine.

The bromides are certainly the best remedies, and the bromide of potassium, in his opinion, stands at the head of the list. The bromide of sodium comes next in efficacy to the bromide of potassium. He thought the bromides affected the nerve centres directly. The mixed bromides are better, usually, than any one of them used singly.

The bromides are advantageously combined with other drugs. The combination which he had found, on the whole, the best for long-continued use, was bromide of potassium, grs. xv; bromide of sodium, grs. xv; solution of the arsenite of potassium (Fowler's solution), ♏ij; conium juice, fʒss, or the fluid extract of conium, ♏iij to v. This was generally made up with syrup of orange and some bitter infusion. Another good combination, mentioned also by Gowers, was the bromide of potassium and tincture of digitalis. It was only especially valuable in cases complicated with weak heart or mitral disease. Monobromide of camphor had no advantage over the bromides. Hydrobromic acid was efficient in very large doses, but so much water had to be given with it that the amount to be swallowed was appalling to the patient. It sometimes irritated the stomach. Borax was not of established value, but helped a few cases temporarily. He found the iodide of potassium, unless especially indicated, had little value when used alone in the treatment of epilepsy. Chloral hydrate is not of much value when given alone, but with the bromides, in cases uncomplicated with cardiac disease, sometimes makes a useful combination. Trousseau's belladonna treatment had been used without noteworthy success. Cannabis indica was not to be depended upon. He had tried cocculus indicus in six cases at the Philadelphia Hospital. None improved, and four were made worse by its use, one of the four becoming insane while taking the drug. At the request of Drs. Reichert and Hinsdale, he had used the nitrate of potassium in seven cases. Of these, only one seemed to be benefited, and some were made worse by its use. When the bromides had to be stopped, the zinc salts or the nitrate of silver were the best substitutes; but they could only be relied on for a short time.

The way to treat epilepsy, in his opinion, was simply to have a plan of treatment, and carry it out over a series of months or years. He would, for instance, first put a patient upon a single bromide, say fifteen grains three times a day, to be increased until a decrease in the number and severity of the paroxysms was produced. He kept him upon this perhaps for a month. He then used the mixed bromides, or some combination of bromides with other drugs, preferably the bromide, arsenic and conium prescription. He watched the condition of the patient, and, if necessary, put him on cod-liver oil, quinine, or iron. With reference to nitrates, bromates, etc., he said that there was probably some chemical or chemico-physiological reason for inefficiency. The *ites* and *ates* would probably *never* give as good result as the *ides*. Mr. Mills believed with Dr. Pepper (*Med. and Surg. Reporter*, January 12, 1884), that close attention should be paid to every point in the daily life of an epileptic—to diet, rest, and hygiene; but he did not, with his present experience, believe that a genuine case of thoroughly developed epilepsy could be cured, or even greatly benefited, without drugs. Harm, however, might be done by over-use of drugs.

Among the surgical and external means of treatment he had successfully used, were, excision of cicatrices, removal of neuroma, actual cautery, and blistering to the neck or head. He said he did not use counter-irritation to the scalp, but was a strong believer in the

actual cautery, used after Brown-Séquard's method, to the nape of the neck.

Dr. E. T. Reichert said that the efficacy of the bromides was certainly not due to the bromine, for bromide of potassium is the best of the bromides, and it contains less bromine than any of the others. The amount of bromine in the chief bromides, as given by Gowers, is as follows:

Bromide of ammonium, . .	81 per cent.
Bromide of potassium, . .	67 per cent.
Bromide of sodium, . . .	77 per cent.
Bromide of lithium, . . .	92 per cent.

All the bromides act alike, but with varying degrees of efficiency. The bromates, nitrites, etc., are not as useful as the bromides. A certain line of similar chemical salts seem to give uniform physiological and therapeutical results.

Dr. Guy Hinsdale said that, in regard to the cases in which Dr. Mills used the nitrate of potassium, some four years ago, one was benefited, some remained the same, while others were apparently made worse by its use.

Dr. Wharton Sinkler wished to know if any of the members had used hyoscyamus, and with what results. He said that Althaus, of London, reported cases in which tincture of hyoscyamus had been used successfully, in doses of from one to three drachms. He said that he had reported one case of epilepsy which had been greatly benefited by cannabis indica, after the bromides and other remedies had failed.

Dr. H. M. Wetherill said that, in his experience, the bromide of potassium was the best remedy. He said he had never tried the tincture of hyoscyamus. He had never seen a case of epilepsy entirely recover.

Dr. F. Dercum said that his experience was summed up in the statement that he found the bromides the best.

Dr. Morris Lewis spoke of the cure of a child, three years old, at the Episcopal Hospital, in which he could obtain no results with the bromide of potassium. The seizures continued, and were worse, if anything. He then resorted to bromide of ammonium, and with immediate good results.

Dr. J. H. Lloyd thought that in cases of epilepsy attention to the digestive functions and to sleep was highly important. He called attention to the observation of Dr. Radcliffe, that epileptics have a tendency to over-eat and to sleep too much. In his own experience, he had found that when constipation was present the seizures were likely to be more frequent and severe. Dr. Radcliffe and other English physiologists seemed to prefer comparatively small doses of the bromides long continued. Dr. Lloyd believed the combination of three bromides with the iodide of potassium to be one of the best in the treatment of epilepsy.

Dr. A. J. Parker believed we could not say that the effect of a drug like bromide of potassium, bromide of sodium, etc., was due either to the bromine, or potassium, or the sodium, etc. Each of these salts is an individual drug, each molecule of which has its own form of motion. Bromine is a substance with its own peculiar molecular condition of motion. Potassium, similarly, has its own motion. Bromide of potassium is the resultant of the two motions. Certain members of the same chemical families, as the bromides, iodides, and chlorides, would seem to go together in therapeutical efficacy, due to similarity of their forms of molecular motion. At any time, we may expect, however, to find wide differences, since our chemical equations simply represent an idea of structure, and tell us nothing concerning the form of molecular movement; and therapeutic effects must certainly depend more on the energy and form of motion than upon any other qualities.

Dr. E. T. Reichert made a few remarks on the use of

HYDROBROMIC ACID AND THE BROMIDES IN SEA-SICKNESS.

He said, while crossing the ocean, he had the opportunity of studying the effect of hydrobromic acid and some of the bromides in sea-sickness. Hydrobromic acid was effectual, but had to be used in such large doses that, owing to the dilution with water necessary, the bulk to be taken was excessive. The bromides were therefore, he thought, to be preferred. Bromide of sodium, in large doses, was effectual in one bad case. He believed that all the bromides were good.

Dr. J. M. Taylor spoke of the use of

NITRITE OF POTASSIUM IN ANGINA PECTORIS.

In an aggravated case of angina pectoris, he had obtained very good results with nitrite of potassium. The patient had been suffering for over a year with paroxysms of increasing intensity, until death seemed imminent. After giving the nitrite of potassium for four weeks, the patient recovered. Nitrite of amyl was used sparingly to control the paroxysms.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, Dec. 23, 1884.

The President, Robert F. Weir, M.D., in the Chair.

Dr. George A. Peters read a paper entitled

CASES OF EXCISION OF SUPERIOR MAXILLA, WITH REMARKS.

(See page 61.)

Dr. J. C. Hutchison said that he would like to express his preference for the removal of the upper jaw for necrosis *without external incision*, and referred to the following case which was reported in full in the *American Journal of the Medical Sciences* for January, 1884. The patient was a girl, eighteen years old, who suffered from phosphorous necrosis of the right upper jaw and malar bone. The cheek was well retracted, and an incision made from the location of the central incisor along the centre of the alveolar ridge back to its posterior margin. The jaw was edentulous. The periosteum was separated from the anterior surface of the jaw around to its junction with the pterygoid process of the sphenoid bone and upward to the malar bone, which was also now found to be dead. This was likewise denuded of periosteum, as was also the floor of the orbit. An incision was then made down to the bone along the transverse palate suture outward to the alveolar process, and another forwards along the middle suture. The periosteum was now separated from the palatine process of the superior maxilla. The spheno-maxillary fissure was perforated and the broadest part of the malar bone

divided directly opposite to the perforation, by a single cut with Isaac's right-angled forceps. The nasal process of the superior maxilla was divided by the same instrument in an oblique direction from the lower termination of the os nasi to the edge of the orbit, leaving the os unguis and the superior extremity of the nasal process of the superior maxilla undisturbed, in order to preserve the lachrymal sac from injury. One blade of the right-angled forceps was then introduced into the right nostril, and the other into the mouth, and the palatine processes of the superior maxilla were separated as far back as the palate bone, by a single cut, and the disunion of the bones concerned was finally accomplished by separating the upper maxillary from the pterygoid process of the sphenoid bone. The jaw was now grasped with a duck-bill forceps, and with a slight twist the whole of the bone (except the upper end of the nasal process) including the orbital plate was readily removed. The malar bone was removed in fragments with the forceps. The periosteum covering the bones was left intact. The palate bones were uninjured, so that the whole of the soft palate was preserved, supported by the palatine plate of the os palati.

At that time, 1872, he looked up the literature of the subject, and was unable to find any case reported in which the entire upper jaw and malar bone had been removed without external incision; whether it had been done since that date he was unable to say. He thought that there are many cases of necrosis of the upper jaw in which this operation can be performed, and regarded it as desirable, especially in women. He was unable to say whether or not bone had been reproduced in his case, or, if reproduced, to what extent; but the only deformity apparent in the photograph, which the patient subsequently sent him, was a slight falling of the right lower eyelid.

VAGINAL HYSTERECTOMY FOR CANCER; RECOVERY.

DR. WEIR presented a specimen of a uterus, epitheliomatous in its lower third, which had been removed by him at the New York Hospital by vaginal hysterectomy, under antiseptic precautions, November 10, 1884. The patient, aged 40, had suffered for nearly a year with obscure pains and discharges. After the uterus had been drawn down by ligatures passed through the cervix, the bladder was separated from it by careful dissection with the finger-end and blunt scissors, until the peritoneal cavity was reached, which was opened, and the uterus, which was considerably elongated, seized at its fundus by a hooked retractor, and tilted forwards through the peritoneal wound into the vagina. Three silk ligatures were passed on each side through the broad ligament, which was then divided close to the uterus, and the organ removed by a final cut through the peritoneum of the cul-de-sac. A single suture approximated the edges of the peritoneal opening, and the ligatures were left protruding on each side. The vagina was tamponed with peat bags, dusted over with iodoform, which were retained *in sitû* for some days, when they were removed. A flow of urine per vaginam was then noticed, which persisted. As in one place the muscular coat of the bladder had been invaded in the dissection to free the organ from the uterus, the urine was supposed to come from an opening formed by the giving way of the thin spot, and some anxiety was felt for a time, since it was also recognized that the right broad ligament had been more than usually encroached upon by the ligature in the desire to get well beyond a suspicious thickening felt in this region. It was feared, therefore, that the ureter might have been involved. A later distention of the bladder with milk while the vagina was opened by a speculum showed that the leakage was in the bladder, though the fistula could not be seen. The opening closed spontaneously December 19. The last ligature came away December 15. The patient left the hospital December 23.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Stated Meeting, December 3, 1884.

THE PRESIDENT, J. M. DA COSTA, M.D., IN THE CHAIR.

DR. ARTHUR V. MEIGS reported a case of

OCCLUSION OF THE VENA CAVA SUPERIOR, AND A CASE OF HEART TUMOR.

A man, aged 72, was admitted into the Pennsylvania Hospital, September 18, 1883. He was strong and well until the past two years, when he had pain in the lumbar region which has increased in the last three weeks, and he has not slept well. The day of his admission he was standing by the edge of the river, looking at some object upon the water, when suddenly and for the first time in his life, he was seized with vertigo, and fell into the water. When brought to the hospital the following note was made: Skin slightly yellow and tongue furred. Radial arteries are markedly stiffened. Veins on the right side of the abdomen and chest enlarged, the largest being half an inch in diameter; those upon the left are comparatively slightly enlarged. Prominent veins extend also toward the right axilla. Examination of the heart reveals a murmur which precedes the impulse and the carotid beat. There is slight visible impulse in the epigastrium.

Sept. 21.—The cardiac impulse is in the fifth interspace, two inches to the left of the sternum, and is rather feeble; there is somewhat more forcible impulse beneath the lower end of the sternum and some visible throbbing of the abdominal aorta. Percussion one inch to the left of the sternum shows the cardiac dulness to begin in the third interspace, and there is flatness at the fourth rib level. Transverse percussion at the fourth rib level shows dulness, beginning at midsternum and extending to the left about four inches. There is distinct impulse in the second interspace to the left of the sternum, and this appears to precede the apex impulse; there is also impulse in the second right interspace, which also precedes the apex beat. There is dulness on percussion in the first interspace to the right of the sternum and in the third interspace, The percussion resonance at the corresponding areas on the left side is normal. There seems to be impaired resonance upon percussion over the upper part of the sternum. The presystolic murmur at the apex is distinct. At the pulmonary area the sounds are very faint but distinct, and the same is the case at the aortic area. At the ensiform cartilage both sounds are distinct, but the first is rather thumping, and is accompanied by a faint blowing murmur which is synchronous with the beat of the carotid artery. There

is no undue pulsation of the arteries of the neck, and the veins are full but do not pulsate. There is a systolic murmur audible in the carotids which is increased by pressure; this is also distinct in the subclavians. There is marked systolic murmur in the femorals and in the abdominal aorta as low down as the umbilicus. Lung examination shows slightly impaired percussion resonance at the right apex, while the note is full at the left. The respiratory sounds are slightly more feeble at the right than at the left apex. Posteriorly the percussion note is short, but not markedly dull. The respiratory sounds are unusually feeble.

23d.—The radial pulse is delayed. Pressure upon the enlarged veins at the lower third of the sternum causes the portion of them below the spot pressed upon to become less prominent and full, and produces a sensation of fulness over the eyes. The veins in the right iliac region tend to be enlarged.

The treatment consisted at various times of iron, iodide of potassium, and strychnia. During the whole time that he was in the hospital he complained bitterly of vertigo, and finally became very much disheartened, and on the morning of December 12th cut his throat, severing the left external jugular vein. After he had lost a great deal of blood, the vein was ligated and he lingered until December 20th, when he died.

Autopsy.—The venous system was injected. In the left pleural cavity, placed superficially just beneath the membrane was seen the left azygos, about one-half an inch in diameter, situated on the bodies of vertebræ and extending from the arch of the aorta to the attachment of the diaphragm below. The veins of communication between the spinal and intercostal vessels were found unusually large.

In dissecting the neck, numerous large veins (several one-quarter inch in diameter), were found passing behind the trachea, and they served as a communication from the right to the left side. They commenced at about the level of the episternal notch and descended into the thorax passing toward the left, and terminated in the beginning portion of the left innominate or transverse vein. The left innominate vein at this part was very much enlarged, and as the vessel advanced toward the right side to join the vena cava, it was found to be converted into a flattened fibrous cord, and this portion was pretty tightly adherent to the surrounding tissues and the branches from the arch of the aorta lying in contact with it.

A probe passed downwards within the right jugular was stopped by an obstruction at a point where the right innominate vein joined the fibrous cord in which the left innominate terminated. From the posterior wall of the right innominate, the probe entered the mouth of a moderate-sized vessel which passed downwards into the thorax; its termination and communications could not be traced; it was supposed to communicate with the right azygos vein, but this vessel could not be found.

On removing the heart the pericardium was found normal. The heart was large, and its ventricular walls were thicker than normal. The mitral orifice was narrowed at its auricular aspect, but its outlet in the ventricle was of normal size. The anterior segment was rendered rigid by the deposit in it of calcareous matter.

The opening of the inferior vena cava appeared larger than normal, perhaps half as large again. The opening of the superior vena cava was found obliterated. A very fine probe could be forced in about an inch by tearing tissues at the normal site of the cava. It was found, therefore, that the obstruction existing above in the innominate vessels was complete and extended to the auricle.

The aorta and its principal branches were very much diseased. Commencing at the aortic orifice, the whole vessel was somewhat dilated, though not aneurismal, and this condition extended to the abdominal portion. Its walls were thicker than normal and very rigid. In most parts of the tube atheromatous changes with calcareous degeneration had taken place, so that in squeezing the vessel between the fingers, the calcareous deposits cracked under the pressure with a gritty sound.

The cause of the compression and final obliteration of the calibre of the superior vena cava with its branches seemed to be due to the rigidity of the aorta together with condensation of the surrounding connective tissues, probably of inflammatory origin. All the connective tissue around the arch of the aorta and first portion of its principal branches was increased in amount and very dense, and firmly adherent to the under surface of the sternum, as well as posteriorly to the bodies of the vertebræ. It was in this tissue that the obliterated venous trunks were found, and to which the tissue adhered so firmly that it was difficult to separate the two in dissection.

The venous blood from the head, upper extremities, etc., found its way to the heart by means of the greatly enlarged veins lying on and around the spinal column posteriorly, particularly the left azygos, as well as anteriorly through the enlarged internal mammary vessels, and the superficial thoracic and abdominal branches. Most of the blood evidently came downwards to the level of the diaphragm and thence found its way directly into the inferior vena cava. Other portions of the blood descended from the superficial portions of the thorax into the abdominal vessels and thence by the lumbar branches to the abdominal vena cava.

The examination of the brain showed a notable fulness of the vessels of both the external and the internal membranes. Small patches of opacity were found on the arachnoid, along the line of the sulci over the convexity. Some of the convolutions showed in places slight degrees of atrophy, and the furrows between them were widened, and at these parts there had accumulated a small amount of clear subarachnoid fluid.

This case was a rare one, and of more than usual interest for several reasons. In the first place, there were unusual opportunities for studying the conditions, both *ante* and *post-mortem*, and the physical signs were such that the diagnosis was made during life. The enlargement of the veins of the surface led to the suspicion that one of the cavæ was occluded, and it was decided that it must be the cava superior, because when the large external veins were emptied for the space of an inch or two with two fingers, the blood evidently flowed much more rapidly and forcibly downwards when the finger nearest the head was first removed, than it did upwards when the lower finger was first removed, and this was the case as much when the patient lay in bed as when he stood, thus showing that the current in the enlarged external veins was down-

wards. Further reasons for thinking that the return circulation from the head found its way back to the heart partly by the external veins, was that, if they were compressed, there was at once produced visible congestion of the veins of the face and suffusion of the eyes, and a sensation of fulness in the head. The presystolic murmur in the heart was very marked and unmistakable, and at all times present while the patient was under observation, and abundant cause for its presence was found in the calcareous deposit with stiffening and roughness of the anterior flap of the mitral valve. The systolic murmur at the base of the heart and in the arteries was caused by the stiffening and roughness of the aortic valve flaps, and of the thoracic and abdominal aorta. It was suspected during life that the arteries of the brain would be found to be stiff, and this was the case; still it is very likely that the vertigo with which the man suffered, and of which he complained more than of any other symptom, may have been partly due to the obstruction to the return circulation from the brain, caused by the blood having to find its way through much smaller and more tortuous routes than the natural ones, and this view would seem to receive further confirmation from the fact that there were found some flattening and shrinking of the brain convolutions. The cause of the dulness on percussion over the upper part of the right side of the chest anteriorly, and the upper part of the sternum which was so distinctly made out, was not understood during life, but the post mortem showed abundant cause for it in the very great amount of hard fibrous tissue around the ascending aorta and veins in that region, and here apparently was the seat of origin of the whole pathological process. It seems most likely that the changes which finally caused a complete occlusion of the whole of the vena cava superior and the larger portion of both the innominate veins had its origin in a periarteritis which must have begun around the ascending or transverse portion of the aorta. This must have proceeded gradually, with a constant increase and condensation of the tissues around the aorta and veins, until at last there was produced the large amount of hard fibrous tissue which the post-mortem examination showed to exist in that region.

CORRESPONDENCE.

THE THEORY AND PRACTICE OF ANATOMY AT THE ANATOMICAL INSTITUTE OF VIENNA.

To the Editor of THE MEDICAL NEWS.

SIR: It has long been a matter of observation and remark by American physicians studying abroad, that European (both British and Continental) medical students about to take their degree of Doctor of Medicine (or license to practise), have a far better knowledge of anatomy than the same class of Americans. The writer believes this to be an undoubted fact, and due to four causes:

1. The longer time of medical work required for graduation abroad.

2. The graded course of study, allowing greater concentration of work upon one or two subjects at a time.

3. The more severe and practical examinations required for a degree.

4. A different and better way of teaching anatomy than is practised in the United States.

The first three causes mentioned are highly important, but do not by any means account for the result, which is in large measure due to the last.

We will take up the method of teaching anatomy in one well-known school, that of Vienna, as perhaps the most practical of all, and see in what it consists. The distinctive method means chiefly, more dissecting and more demonstrating of human anatomy to students, at their dissections and in separate courses in topographical anatomy. An elementary knowledge of comparative anatomy is required before graduation, which greatly helps to fix the multitude of facts in human anatomy in the memory, and gives an intelligent basis for further study.

The student *must* spend several months in the "annex" to the dissecting-rooms before he begins actual work with the scalpel. This "annex," as it may be called, comprises three rooms, one of which contains a large number of chests, each for certain bones; for example, one for vertebræ, one is full of ribs, one for skulls, another for femurs, etc. The walls are covered with large plain diagrams, and the rest of the room is occupied by tables, on which to put the specimens for study. These bones may be freely used by all students, with the restriction that they shall not be taken from the room or injured. A small number have to be replaced each year.

In an adjoining room are a number of the glycerine-carbolic preparations, for studying the muscles. In these the parts are about of their normal size, and consistence, everything being dissected away, except the bones, ligaments, and muscles. One such preparation, properly made, will stand about six weeks of constant handling by students. In another room are excellent alcoholic specimens of the heart, lungs, stomach, larynx, brain, etc., which may be taken out of their tanks and laid upon zinc trays for examination. To replace these as soon as they are used up, several advanced students are at work most of the time.

Meanwhile, the student attends the regular lectures upon anatomy by the University professor. When he is finally quite familiar with the skeleton, ligaments, muscles, and viscera, and has a good preparatory knowledge of vessels and nerves, he first enters the dissecting-room, has a locker assigned him for his instruments, dons a long black gown which entirely protects his clothes from being soiled, and is given an arm or a leg, separated from the trunk, upon which to commence work. The advantage of having an extremity which one can quietly dissect in one's own time and way, is very great for a beginner.

The dissecting rooms proper are far from ideal in the great essentials of space, light, and ventilation. In 1848, when the medical students took such a prominent part in the Revolution the anatomical institute was destroyed, and the Austrian government has declined to build another up to the present day. Some of the departments will soon be quartered in the splendid new buildings upon the "Ring," but anatomy, as the "fons et origo mali" must abide in the old armories which she now occupies. The rooms for student work are

three, and are on the ground floor. In addition are the injecting room and the prosectorium. In the latter the dissections for the regular lectures are made, and the courses in topographical anatomy given. Upon another side of the hollow square is the museum which contains many fine preparations by Hyrtl, and the able men who preceded or have followed him as professors or prosectors.

In the same building is the amphitheatre, and there are numerous smaller rooms for private work by the faculty, which consists of one professor, an adjunct-professor, a prosector, a demonstrator, and several assistant demonstrators. The rooms for student work are kept very clean. The floors are made of a smooth cement which can be washed every night, when the refuse is also carried away, and the place thoroughly aired. The dissecting tables are covered with zinc, have a raised edge, and slope toward a hole in the centre, from which blood, etc., escapes into a zinc pail beneath.

For student work cadavers or parts are not, as a rule, injected with any preservative solution, and no injection whatever is employed in the earlier dissections, that the students may become accustomed to tracing empty arteries, and not embarrassed by the presence everywhere of distended arterial twigs. The janitor performs such injections as are done with the ordinary wax and resin composition. It is good practice for the advanced student to do this himself, and it can usually be arranged without trouble. I have injected numerous extremities, as well as infants, with the hot injection in use here, and have never been obliged to heat the part in any way, the composition if properly melted, or thinned at the last minute by the addition of a little turpentine, will run to the very tips of the fingers and toes; indeed a small cut is usually made in the thumb or great toe, as the case may be, and all force on the piston stopped as soon as the injection escapes from this incision. The syringe is quickly withdrawn, a plug inserted in the canula, and cold water dashed over the part to solidify the injecting material. The formula for the hot injection is as follows:

R.—Yellow wax,	1 kilogram.
Resin,	1 kilogram.
Venice turpentine,	2 tablespoonfuls.

Melt the first two, add the turpentine, and then enough cinnibar to color sufficiently. A tablespoonful to a small bowl of melted injection is about the proper amount. Add a little more turpentine when remelting the injection for use.

What finds most favor is the new Teichmann's injection. It was introduced in my first winter in the Anatomical Institute, and two years later it had steadily gained ground. It is used principally for injecting extremities, heads, or parts of the body, and is not so well adapted for an aortic injection. The advantages it possesses over most others is, 1. It is a cold injection; 2. It will run to the finest arterioles, if desirable; 3. A slight alteration in the formula will enable one to use it for veins and lymphatics; 4. It remains flexible for a number of days, and the fine vascular twigs do not break in a prolonged dissection; 5. It is insoluble in alcohol, and can thus be used for spirit preparations. The disadvantages are, 1. That it requires the use of bisulphide of carbon, although when properly made, or used there is little escape of the vapor of this substance; 2. It requires a syringe with a screw piston, and some little experience to get the injection neither too thin nor too thick, and to use enough force without bursting the vessels. The following are the formulæ:

For an entire cadaver:

	Coarse.	Fine.
R.—Finely powdered and sifted chalk,	1500 gm.	300 gm.
Cinnabar,	300 "	100 "
Linseed (boiled) oil,	300 "	120 "
Bisulphide of carbon,	150 cc.	100–200 cc.

Mix the first three to the consistence of a stiff putty. This may be kept under water several days, if necessary. Rapidly add the carbon bisulphide just before use. The coarse injection should have finally the consistence of thick paint; the finer, about that of molasses.

For an extremity:

	Coarse.	Fine.
R.—Chalk,	300 gm.	100 gm.
Cinnabar,	60 "	20 "
Linseed oil,	60 "	24 "
Bisulphide of carbon,	30 cc.	20–40 cc.

Blue injection:

R.—Zinc white,	150 gm.
Ultramarine,	1 "
Linseed oil,	150 "
Bisulphide of carbon,	10–15 cc.

For lymphatics:

R.—Zinc white,	20 gm.
Linseed oil,	3 "
Bisulphide of carbon,	2 cc.

Great care must always be used to get a fine variety of chalk. The solid ingredients should be very thoroughly mixed with the oil, and the bisulphide of carbon added just before use, under a flue. Plenty of time should be taken in injecting, and the screwing up of the piston suspended as soon as the large vessels become very tense; when they relax a little another turn or two of the piston may be given. A part injected in the afternoon is ready for dissection the next morning. Enough of the bisulphide evaporates to leave the injection quite firm. It is possible that some of the benzole series might be used as a substitute for the bisulphide of carbon, being both cheaper and less offensive to work with. I have tried, without success, to substitute sulphuric ether.

It is very unusual at the Anatomical Institute for anything worse than slight constitutional disturbance and enlarged axillary glands to follow dissecting wounds. If the glands remain enlarged longer than a few days, they are treated by inunction of mercurial ointment over the skin of the axilla. This treatment appears to be very successful. A few drops of fuming hydrochloric acid poured into the palm of one, and immediately rubbed over both hands, is used to destroy the persistent odor adhering to them after dissecting a stale part, and it is more efficient than anything I have used.

Americans who wish to devote all their time to dissecting, can, in some cases, secure a private room in the Institute for that purpose. Material is, as a rule, plentiful, in spite of the large amount used. The dissection of an extremity is expected to be finished in a

week or, at most, ten days. In addition to the regular supply of cadavers of adults, bodies of infants from the foundling hospital are brought to the dissecting-rooms, often at the rate of three to ten a day. They are especially convenient for tracing out nerves.

One of the best features of the Vienna plan of instruction is the course on topographical anatomy. In this course ten or twelve men gather about a table on which a demonstration is held, and the entire body gone over in regions. The students are so near that each one can plainly see, and, if need be, touch the parts as they are shown and described. It is a most effective method of impressing anatomical facts upon the memory. Combined with some reading and persistent dissecting, it leaves little to be desired.

The common plan of holding didactic lectures upon descriptive anatomy, with a cadaver so far away from the students that no one can see anything satisfactorily, is a relic of former times, when dissection was permitted to a few only, and material was very scarce. We believe that the time spent in attending such lectures, apart from what is taught regarding the action of the muscles (and that properly belongs to physiology), is almost wasted. A much better method would be to have a corps of capable demonstrators—one to every ten or twelve students and this in a graded course would not be many—who should give one or more daily demonstrations in anatomy, each to his own division. They might be appointed for terms of three years each; one or more to go out of office each year, and their places to be filled from among recent graduates by competitive demonstrations. The salary of one professor divided among (we will say) four demonstrators, together with the benefit of three years of dissecting and teaching, would insure plenty of good applicants. The short tenure of office and the competition would yield a maximum of good work, while the advantages of a more thorough knowledge of anatomy to surgeons and students, who should teach and be taught, would be widely extended.

WALTER B. PLATT, F.R.C.S. (Eng.).

BALTIMORE, Jan. 10, 1885.

DR. STERNBERG'S VIEW OF THE ACTION OF POTASSIUM PERMANGANATE AS AN ANTISEPTIC.

To the Editor of THE MEDICAL NEWS.

SIR: In your last issue Dr. Sternberg publishes a paper reviewing some of the points discussed by me in a brief memoir on the Permanganate of Potassium, which appeared in THE MEDICAL NEWS for Nov. 22, 1884. I do not reply to this review in a fault-finding spirit. The additional reasons which Dr. Sternberg has advanced, derived as they are from a peculiarly difficult and laborious investigation, which he is carrying on, must be regarded as so much new matter of an illustrative character, contributed to a recondite subject. For these gratuitous labors, as he intimates, an investigator ought, at least, to receive the meed of intellectual appreciation from the medical public. To have his conclusions questioned seems but a poor return for so much purely scientific work undertaken and carried on for the general benefit. Far be it from me to lessen one jot of the respect which should be entertained for Dr. Sternberg's important investigations. But there may be honest differences of opinion in regard to methods and results—when the subject under discussion is still *sub judice*. I wish merely to support my own views on one point. Dr. Sternberg makes a distinction between *antiseptic* and *germicide*, and he holds those to be in error who use them as synonymous terms. I must confess that I am not convinced by Dr. Sternberg's arguments. They yet seem to me to be convertible terms.

A germicide is an agent that kills germs—ferments or organisms.

An antiseptic is an agent that prevents or arrests septic change.

In the present state of the knowledge on this subject, septic metamorphosis is correlative of the growth and multiplication of certain minute organisms. Remove these organisms and prevent the access of others—in other words, *sterilize* the fluid—all change, fermentation, or decomposition is prevented. That is a true antiseptic which inhibits or destroys the septic agent—a minute organism—and, therefore, it is also a germicide.

I need hardly say that the term deodorizer is quite distinct from antiseptic, and they cannot be used in the same sense. But an antiseptic is necessarily a germicide, and a germicide is necessarily an antiseptic so long as the doctrine of Pasteur regarding the agency of minute organisms in all fermentative processes is held.

ROBERTS BARTHOLOW, M.D.

NEWS ITEMS.

NEW YORK.

(*From our Special Correspondent.*)

CENTRALIZATION IN THE HOSPITALS seems to be the order of the day. There is an evident inclination of medical men to devote themselves to one service, and through resignations, the staff at some of the hospitals—the New York and Roosevelt especially—are greatly reduced in number. At the latter all the surgery is in the hands of Dr. Sands and an assistant.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.—At the annual meeting of the College, held on January 7, the following officers were elected for the ensuing year:

President.—J. M. Da Costa, M.D.
Vice-President.—S. Weir Mitchell, M.D.
Secretary.—R. A. Cleemann, M.D.
Treasurer.—Charles S. Wurts, M.D.
Recorder.—J. Ewing Mears, M.D.
Honorary Librarian.—James H. Hutchinson, M.D.
Censors.—Lewis Rodman, M.D., Edward Hartshorne, M.D., William Goodell, M.D., Alfred Stillé, M.D.
Councillors.—For three years, I. Minis Hays, M.D., and Arthur V. Meigs, M.D. For one year, Robert P. Harris, M.D.

UNIVERSITY OF THE CITY OF NEW YORK.—DR. AMBROSE L. RANNEY, Professor of Applied Anatomy in the Post-Graduate Medical School of New York City, has been appointed to fill the Chair of Anatomy in the Medical Department of the University of New York, rendered vacant by the death of Prof. William Darling.

University of Vermont.—At a meeting of the Medical Faculty of the University of Vermont, Dr. Ambrose L. Ranney was unanimously elected to succeed the late Dr. Darling as lecturer on anatomy.

The Extension of Tuberculosis.—The Austrian Minister of the Interior, we learn from the *Wiener med. Presse* (December 21, 1884), has called the attention of the infirmaries and larger hospitals of his country to an official circular in which the management of tuberculosis is considered at length. Inasmuch, as it is now the prevailing opinion that tuberculosis is caused by a specific bacillus, phthisis must also be considered an infectious disease, and all precautions are to be exercised concerning it which have hitherto been observed in regard to other infectious diseases.

The hospitals are directed to take into consideration the complete isolation of patients suffering from phthisis and also to employ all other prophylactic measures necessary to prevent the extension of the disease. It is further directed that the results of the observations in relation to this subject be forwarded to the Minister of the Interior.

The Report of the English Cholera Commission.—The following is the text of the preliminary report presented by Drs. E. Klein and Heneage Gibbes to the Surgeon-General and Sanitary Commissioner with the Government of India:

We have the honor to report that the investigations which we have hitherto carried on in Bombay and Calcutta have yielded the following results:

1. The statement of Koch that "comma-bacilli" are present only in the intestines of persons suffering from or dead of cholera is not in accordance with the facts, since "comma-bacilli" occur also in other diseases of the intestines—*e. g.*, epidemic diarrhœa, dysentery, and in intestinal catarrh associated with phthisis.

2. The "comma-bacilli" in acute typical cases of cholera are by no means present in such numbers and with such frequency as to justify Koch's statement that "the ileum contains almost a pure cultivation of comma-bacilli."

3. The "comma-bacilli" are not present in the tissue of the intestine or elsewhere.

4. The "comma-bacilli" in artificial cultivations, carried out by one of us (E. K.), do not behave in any way differently from other putrefactive organisms.

5. Mucous-flakes of the ileum, taken out soon after death from typical acute cholera, contain numerous mucous corpuscles, many of them filled with peculiar minute straight bacilli. The same bacilli occur also outside the mucous corpuscles. They are never missed even when the "comma-bacilli" are.

6. These small bacilli have been cultivated by one of us (E. K.), and they do not behave differently from putrefactive organisms. These small bacilli are not present in the tissues of the intestine or any other tissue.

7. No bacteria of any kind, and no organisms of known form and character, occur in the blood or any other tissue.

8. A good many experiments have been carried out by one of us (E. K.), with the following results: (*a*) Mice, rats, cats, and monkeys were fed with rice-water stools, with vomit, with mucous-flakes of the ileum, fresh and after having been kept for twenty-four to forty-eight hours. The animals remained normal. (*b*) Inoculations with recent and old cultivations of "comma-bacilli," and the small straight bacilli, as well as with mucous-flakes, were made into the subcutaneous tissue, into the peritoneal cavity, into the jugular vein, and into the cavity of the small and large intestine of rabbits, cats, and monkeys; but the animals remained perfectly well and normal.

9. The material which we have had hitherto at our disposal has been very good and abundant, and, as far as the microscopic work goes, we do not think we shall require any more material.

We therefore propose concluding our inquiry by the beginning of December, and hope soon after to return to England.—*Med. Times and Gazette*, Jan. 3, 1885.

Obituary Record.—Professor Franz Chvostek died in Vienna, on November 16th, in the fiftieth year of his life. He is well known for his valuable contributions to German medical literature. In the event of the reopening of the Josephinum Akademie in Vienna, he was to occupy the Chair of Internal Medicine.

—— Prof. Vierordt died on the 22d of November, at the age of 67 years, a short time after the resignation of his professorship. His work upon the *Doctrine of the Circulation* entitles him the credit of being the originator of the use of the sphygmograph. Of equal importance were his *Investigations upon the Velocity of the Blood Current*, and the *Physiology of Childhood*.

Vierordt also attained distinction in the domain of mental physiology. His *Elements of the Physiology of Man*, of which several editions appeared, was in its time a most useful book.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 6 TO JANUARY 12, 1885.

Head, Jno. F., *Colonel and Surgeon.*—Retired from active service, by operation of law, on January 9, 1885, under provisions of Act of Congress approved June 30, 1882.—*S. O. 7, A. G. O.*, January 9, 1885.

McKee, J. C., *Major and Surgeon.*—Ordinary leave of absence still further extended four months on surgeon's certificate of disability.—*S. O. 6, A. G. O.*, January 8, 1885.

Shannon, Wm. C., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Bridger, Wyoming, and assigned as Attending Surgeon at Headquarters Department of the Platte.—*S. O. 2, Department of the Platte*, January 5, 1885.

Robinson, S. Q., *Captain and Assistant Surgeon.*—Assigned to temporary duty at Portland, Oregon, from December 17, 1884.—*S. O. 206, Department of Colorado*, December 22, 1884.

Wales, P. G., *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Vancouver Barracks, Wyoming Territory, and ordered to return to his proper station, Fort Cœur d'Alene, Idaho.—*S. O. 204, Department of Colorado*, December 19, 1884.

The Medical News *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

All communications relating to the editorial department of the News *should be addressed to No. 1004 Walnut Street, Philadelphia.*

ORIGINAL LECTURES.

EPITHELIAL CANCER OF THE EYELID.

A Clinical Lecture delivered at the Cincinnati Hospital.

BY ROBERT SATTLER, M.D.,
OF CINCINNATI, OHIO.
(Reported by C. H. CASTLE, M.D.)

GENTLEMEN: I desire to call your especial attention to the following cases, as they represent several clinical and histological varieties of a most interesting affection, the discussion of which will occupy our attention this morning. These cases represent so fairly the types you will find described in your books, that no doubt many of you can surmise from your seats the nature of the disease. It is known to the surgeons of this country as epithelioma; in England it frequently takes its name from the locality in which it is found, as, for instance, "smoker's cancer" when found upon the lip, "chimney-sweep's cancer" when found upon the scrotum. To the French it is known as "fragile cancer," a term descriptive of one of its chief physical characteristics in most cases, and by the Germans it is called epithelial carcinoma or cancroid.

Epithelioma may be described as a neoplasm which histologically has a distinct epithelial type, and which consists chiefly of tissue composed of one of the varieties of epithelial cells. The latter are embedded in a more or less vascular stroma composed either of adult, embryonal, or mucous connective tissue.

Clinically, and this applies also to the lids and the orbital cavity, we can make two grand divisions of this cancer into *superficial* and *infiltrating*, which two divisions again present varying characteristics and appearances which claim recognition and description.

This old man, a Swiss, aged 69, presented himself at my clinic two weeks ago, exhibiting what was at once recognized—the diagnosis being verified by microscopic examination—as a superficial epithelioma at the outer canthus of the left eye. According to his account, it had appeared as a small, round, whitish, slightly elevated patch some fifteen years before. Subsequently papules of a waxy hue developed, forming a growth of an oval form. When the size of a half dime the centre became depressed, and the surrounding border nodular. Eventually ulceration began in this central depression and at times a thick scab would cover the ulcerated surface. The only subjective symptoms that he complained of were the needle-like pains that occasionally passed through the growth and the discomfort that it occasioned to his eye, for, as you will see, peripheral cicatrization has caused a decided degree of ectropium of the lower lid. When he was first examined the diameter of the growth measured 10 by 17 mm. The treatment adopted in this case has resulted so favorably, that no correct conclusion can be formed from the present smoothly cicatrized appearance, of the dimensions of the growth before operation.

Besides the flat variety of superficial, or so-called lobulated pavement epithelial cancer, of which this old man presented a most typical example, we find other varieties the clinical characteristics of which we must bear in mind, in order, in many cases, to arrive at a correct diagnosis. Sometimes the infiltration presents a distinctly warty appearance, in others the external cells undergo an absolute cornification and we find the growth assuming the shape and appearance of a projecting horn, a most excellent example of which was observed recently. In this case a large horny outgrowth was removed from the right lower lid and cheek, measuring an inch in length and some three-quarters of an inch in diameter at its base. Again, but rarely, we find them in a condition of calcification and an abundant deposit of lime salts takes place in the older parts of the growth.

A not infrequent form of the superficial epithelioma is what is known as the cicatricial variety. The infiltration breaks down in patches or involves a large area of the growth and bands of cicatricial tissue traverse it in various directions, producing the well-known deformity of irregular scar-tissue.

A very characteristic form of this first or superficial type is the rodent variety. The term rodent ulcer and its synonymes, "Jacob's ulcer of the eyelids," etc., are familiar to all of you. By most authorities of weight, this "ulcer" is recognized as a rodent form of epithelioma. It is a rapidly progressive and eminently destructive process, which appears engrafted on the specific growth. It assumes a definite plan of advance, often a circular, circinating, or scalloped border marking its progress. From its malignancy and its rapidly destructive course, it is much to be dreaded, and what is perhaps peculiar, it betrays an affinity rather for the superficial than for the infiltrating variety. Leading the advance of this rodent ulcer is a growth of waxy nodules; the ulceration itself progressing by excavating the wall of its advancing border, presenting to the eye and touch a clean, glazed surface, and followed in its march by a peculiar, thin, white, glistening cicatrization, which, once seen, is never forgotten. In addition to the rodent, the superficial may manifest the papillomatous variety —papillæ-like prominences covered with irregular fringe-like projections.

In this woman, a German, aged 62, I present to your notice a typical example of the second or infiltrating variety of epithelioma. This begins generally as a superficial nodule. If, however, the starting-point is from the glandular structures—sebaceous, sweat gland, etc.—of the skin, it may appear in the form of a deep infiltration. Its course may be slow or rapid; it may assume a rodent or papillomatous characteristic. It may destroy the bones of the orbit and result in frightful deformity. In this case the disease is of twenty-two years' duration; it has resulted in complete destruction of the lower lid and has invaded the superficial and deep structures of the cheek and nose. The upper part of

the left lateral cartilage of the nose is gone and the left ala drawn up, and the upper lid of the same side bound firmly down by peripheral contractions.

Her general health is good. The proximal lymphatics are not implicated. Lancinating or needle-like pains constitute her chief complaint. Not infrequently this form assumes a papillomatous type and presents a peculiar soft warty or fringe-like development.

I have here in alcohol the eye and tumor of a patient aged 62. An extensive operation was performed about six months ago. It consisted in a thorough extirpation of all the contents of the orbit and a thorough scraping and denudation of its bony walls. In this case fungoid masses were found over the entire growth, which had destroyed the lower and three-fourths of the upper lid, and had in addition attacked the cheek, the globe, and the bony walls. The eyeball was rigidly fixed by firm and unyielding adhesions to the upper and inner wall of the orbit.

This second photograph illustrates to you an extensive rodent form of ulceration engrafted on the infiltrating variety.

It has been in progress for thirty years. The destruction is very extensive. The contents of the orbit, even the bony walls and the entire right side of the face, soft structures and bone, have been involved in the steadily progressing destructive disintegration. No implication of the proximal glands, no hemorrhage or excessive pain, and no constitutional disturbance has so far resulted. The upper and inner portion of the orbital cavity is studded with gelatinous granulations and a tumor, most probably a meningocele, exists.

Pathologically, we can recognize three varieties of epithelioma—the pavement cell cancer, the cylindrical cell cancer, and, according to German authorities, a third, rare form, the glandular cell cancer.

Under the microscope, the pavement cell cancer is recognized by certain characteristic appearances. Taking a section through the epidermis, the rete mucosum and the derma, we find that in the papillary layer of the skin a cell evolution is going on, the process apparently being the reverse of that which takes place in the normal development of the epidermis. At the periphery of the new tissue we find small, cylindrical nucleated cells—the succeeding cells are larger, cubical, or flat, while the most internal cells are concentrically laminated about a centre and flattened to the highest degree. These are the "nests," "pearl globules," or "globes epidermique."

Sometimes we find these flattened cells grouped in lobules or packed in long irregular shaped tubules, and from these appearances are made two divisions of the pavement cell cancer: the superficial lobulated and the deep or tubulated.

The arrangement of the cells in a cylindrical cell cancer corresponds to the normal arrangement of cylindrical epithelium—it is single celled. The cells, however, are perhaps larger and less regularly cylindrical —those in the centre of the growth may even be round. The stroma of both pavement and cylindrical cancers is composed of adult or embryonal connective or mucous tissue, and may be found combined in the same growth. It is very vascular, its bloodvessels, however, not penetrating in among the epithelial elements.

These growths have decided preferences as to habitat. The face is a favorite seat and particularly the junction of a mucous and cutaneous surface. In the order of their frequency of attack we find first, the lower lip, then the nose, cheeks, eyelids, brow, temporal region, upper lip, chin and ear. Histologically the sebaceous, sweat, and lymphatic glands and the connective tissue can all be looked upon as starting points.

As to the etiology of epithelial cancer, we have very little positive knowledge. We know that it is usually a disease of advanced life, that it in many cases, but not by any means invariably, is the result of a local irritation. Beyond this we cannot go. Some eminent pathologists maintain that a cancerous diathesis must exist in the individual, others that it is merely the local result of some long-continued irritation.

The course of the disease is exceedingly variable, and, of course, much influenced in many cases by prompt and energetic treatment. We will undoubtedly find many cases dragging on ten, fifteen, twenty years or longer, and evincing no particularly malignant symptoms, while others terminate by exhaustion or hemorrhage in a comparatively short period.

The diagnosis does not present many difficulties. From lupus ulcer it can be differentiated usually by its color, by the tubercular appearance of lupus, sometimes by the discharge in the latter and by the microscopic appearance. From a chancre it can be differentiated by the amenability of the latter to antisyphilitic treatment. From other varieties of cancer by its appearance at its favorite sites and by its non-involvement of the proximal lymphatics.

A certain and never-failing source of diagnosis is the microscopic appearance of the growth.

When we turn to surgical or dermatological authorities for methods of treatment of epithelioma we find a surprising unanimity of opinion. Almost without exception we find that excision and the caustics occupy their highest estimation. The author of the chapter on diseases of the lids, Michel, in Gräfe and Saemisch's *Handbook of Ophthalmology*, also assigns the first place to excision and the caustics, and only refers briefly to the method of scraping suggested by Volkman, of Halle, Germany.

Hebra, Kaposi, Neumann, Auspitz, and also Duhring, refer to this method, without, however, assigning to it better or more satisfactory results or advantages over the methods already referred to. All the text-books on the eye either do not refer to it at all or give it only a brief notice. A recent text-book by Juler, of London, England, is, perhaps, the only exception.

The method which I have adopted in these and other cases, with most gratifying results, consists in the use of a small but strong steel curette or scraping-spoon. To be followed by good results, it must be resorted to in a thorough manner, and *all suspicious-looking or fragile tissue* must be removed. The hand, by the sense of resistance, easily determines when the cancerous tissue has been removed and the instrument is in contact with healthy tissue. This applies particularly to the superficial (cutaneous) forms of the disease, and, if it has invaded only the skin, this method will, in almost every case, effect a satisfactory disappearance. In the deeper forms, to be effectual, it must be resorted to more radically, and in many cases the knife and bone gouge are necessary in addition.

In the case of the old man, there has been but one scraping; the result has been most satisfactory. The parts were pencilled with a four per cent. solution of cocaine, and the pain attending the operation was greatly reduced. Cold applications were made, and no local reaction or pain resulted, and a superficial and regular cicatricial covering exists. In the case of the woman the disease had progressed beyond the power of the curette, the knife, and the various caustics to eradicate it, but, beyond doubt, for the past two years, during which she has been a weekly attendant at my clinic, it has been greatly held in check; hemorrhage has been prevented, pain made to disappear, and these results, most excellent for this case, have been accomplished solely by the use of the scraping method.

The advantages of this method in the locality of the lids over excision, the use of the various zinc, arsenic, and caustic potash salves and pastes, the mineral acids, or the actual, thermo or galvanic cautery, etc., are, first, over excision, that the defect is not larger nor deeper than the infiltration and that plastic operations are not necessary to cover the defect; over the caustics, that the adjoining healthy regions are not implicated and the pain is much less. This applies to the various caustic pastes and galvanic or thermo-cautery. The chief advantages of the scraping method in those cases in which it is applicable—*i. e.*, all the superficial and some of the infiltrating forms—are the simplicity and ease of this method compared with others; the healthy tissues are but slightly or not at all disturbed, little or no danger from inflammatory reaction or pain after the operation, the formation of a superficial cicatricial covering and therefore either less or at least no greater deformity than existed before the operation.

These are advantages which cannot be overestimated when compared with the risks attending excision and plastic operations in this locality, or the pain and protracted ulceration which may invade the adjoining territories when caustics are chosen as the curative agents.

This remark is based upon a large number of observations, extending over a period of years and applies particularly to epitheliomata of the eyelids. It has yielded, in my experience, the most gratifying results, and I do not hesitate to recommend it to you as the method in a large number of cases which you can adopt with better prospects of success than all other surgical or caustic methods, either separate or combined.

DISINFECTANTS.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

INTRODUCTION.

AT the recent meeting of the American Public Health Association, held in St. Louis, Mo., October 14–17, 1884, Dr. James F. Hibberd, of Indiana, introduced resolutions calling for the appointment of a committee to investigate the subjects of "disinfectants, germicides, and antiseptics," and formulate the results of their research, so as to make the existing knowledge on these topics available for professional and popular use. This is the purport of the resolutions which were adopted by the Association. A Committee was accordingly appointed, consisting of Major George M. Sternberg, Surgeon U. S. Army, Baltimore; Dr. J. H. Raymond, Professor of Physiology and Sanitary Science in Long Island College Hospital, and Health Commissioner of the city of Brooklyn; Dr. Victor O. Vaughan, Professor of Chemistry in the University of Michigan; Dr. W. H. Watkins, Medical Director of the Auxiliary Sanitary Association of New Orleans; Major Charles Smart, Surgeon U. S. Army, Washington; Dr. A. R. Leeds, Professor of Chemistry in Stevens' Institute of Technology, Hoboken; and Dr. George H. Rohé, Professor of Hygiene in the College of Physicians and Surgeons, Baltimore.

At a meeting of the Executive Committee of the American Public Health Association, held in Washington on December 11, 1884, the Committee on Disinfectants was authorized to publish and make available to sanitarians and the public the results of its labors at as early a date as practicable, in view of the possible invasion of this country by cholera during the coming summer. A preliminary statement of the work of the Committee has already been made to the Conference of State Boards of Health, in session in Washington, December 11 and 12, 1884.

In order to be enabled to pursue a thorough scientific research, the Committee, after consultation, decided to appeal to city and State boards of health, and to sanitary associations for financial aid. Responses to this appeal have been encouraging, and the Committee flatters itself that the work now in progress will yield results of very great practical value.

A complete investigation of both disinfectants and antiseptics being impracticable in the time and with the resources at command, the Committee decided upon so far departing from the letter of the resolutions of Dr. Hibberd, as to limit its inquiry altogether to disinfectants, and to omit all investigations into the action of antiseptics. The Committee would define a disinfectant as an agent capable of destroying the infective power of infectious material. In its experimental investigations, the Committee has adopted the biological test upon known disease germs or allied organisms. The details of the methods pursued will be given by Dr. Sternberg in a subsequent paper in this series. Provisionally, it may be stated that in the experiments material containing zymogenic or pathogenic organisms is exposed for a definite time to the action of a measured quantity of the supposed disinfecting agent. If the vitality of the test-organism is destroyed, if it is rendered incapable of subsequent reproduction or development when placed under favorable conditions, the test is regarded as satisfactory. If, however, the organism should grow, subsequent to its exposure to the agent to be tested, disinfection has not followed.

At a meeting held in Baltimore on November 20th, the Committee was divided into two sub-committees, one consisting of Drs. Sternberg, Smart, and Rohé,

to examine the literature of disinfectants, and abstract and tabulate the results, and to investigate in an exact manner in the laboratory the relative germicidal value of the various substances used as disinfectants. The latter part of the inquiry is exclusively under the direction of Dr. Sternberg, the Chairman of the Committee, who has been granted exceptional facilities for carrying on this work in the biological laboratory of the Johns Hopkins University in Baltimore.

The second sub-committee consists of Professors Raymond, Vaughan, and Leeds, and Dr. Watkins, and will have especially to investigate the practical application of such disinfectants as are found efficient, upon a large scale, their cost, methods of use, chemical relations, effects upon furniture or fabrics, or their possibly poisonous effects upon human beings or animals. Preliminary reports from members of this sub-committee will also appear in this series of papers.

In this way, the Committee hopes to fulfil the expectations of the American Public Health Association and others interested, and to render available, before the arrival of the next epidemic season, all knowledge of practical value upon the important subjects of disinfectants and disinfection.

The Committee considered it unnecessary to make any original experiments at present upon the disinfecting powers of the haloid elements—chlorine, bromine, and iodine. In accordance with a suggestion of the Chairman, the writer presents herewith the results of an examination of the recent literature upon the disinfectant action of these substances.

I.

CHLORINE, BROMINE, AND IODINE.

By GEORGE H. ROHE, M.D.,
Professor of Hygiene in the College of Physicians and Surgeons, Baltimore.

Chlorine.—The most thorough and exact research into the disinfectant powers of chlorine on record, is that made by Fischer and Proskauer, and published in the second volume of *Mittheilungen aus dem Kaiserlichen Gesundheitsamte.* The material tested consisted of the spores of bacillus anthracis, spores of the various forms of bacilli found in ordinary garden soil, micrococcus tetragenius, micrococcus prodigiosus, bacillus of septicæmia of mice, bacillus of septicæmia of rabbits, aspergillus nigrescens and aspergillus ruber, micrococcus of erysipelas, sputum of tuberculosis, bacillus anthracis, bacterium of fowl-cholera, and various other non-pathogenic microörganisms.

The observations were made both in dry air and in air artificially moistened, and the objects to be disinfected were sometimes exposed in a dry, sometimes in a moist condition. The concentration of the gas varied from 1 part in 25,000 to 1 part in 2¼. The time of exposure in the different experiments varied from one to twenty-four hours.

Anthrax spores when thoroughly desiccated and exposed to the action of a dry chlorine atmosphere containing 44.7 parts of chlorine in 100, resisted the disinfectant action of the agent completely for one hour. After three hours' exposure, germination was still free, but somewhat retarded. After twenty-four hours' exposure, disinfection was complete, the vitality of the organism being entirely destroyed.

When the air in the experimental chamber and the spores were moistened, one hour's exposure to an atmosphere containing four per cent of chlorine was sufficient to produce complete disinfection. If the exposure was continued for three hours, one per cent. of chlorine was an efficient disinfectant; and if the spores were exposed for twenty-four hours, the effective proportion of chlorine could be still further reduced, if the air and objects to be disinfected were first rendered moist.

Bacillus anthracis itself was killed in moist air, if chlorine was present, in the proportion of 1 part in 2500 after twenty-four hours' exposure. Even with such a minute proportion of chlorine as 1 part in 25,000, the development of the organism was scanty and retarded.

Spores of the various forms of bacilli found in ordinary garden soil proved a little more resistant to the action of the chlorine. When the air in the experimental chamber was very moist, however, the presence of one per cent. of chlorine, and upwards, rendered the spores incapable of development after three hours' exposure. When the chlorine strength was four per cent., one hour's exposure was sufficient to destroy the germinative power of these spores.

Micrococcus tetragenius was killed in moist air by the presence of so small a proportion of chlorine as 1 in 25,000, if the exposure was prolonged to twenty-four hours. Exposure for less than three hours was not sufficient to destroy the life of the organism in all cases.

Micrococcus prodigiosus, and several other varieties of pigment-forming micrococci, showed themselves generally more resistant to the disinfectant than micrococcus tetragenius. In other respects, they behaved similarly, exposure for upwards of three hours being sufficient to destroy them in the presence of over four per cent. of chlorine.

Aspergillus nigrescens and aspergillus ruber were rendered incapable of further growth by exposure for one hour to moist air containing 1 part of chlorine in 25,000.

Micrococcus of erysipelas was killed by three hours' exposure to moist air containing 1 part of chlorine in 2500, or twenty-four hours' exposure to air containing 1 in 25,000.

Bacillus of septicæmia of mice was killed by exposure to an atmosphere containing from 3 to 40 parts of chlorine per thousand. The presence of 5 parts per thousand was effective after one hour's exposure in a moist atmosphere.

Bacillus of septicæmia of rabbits was killed by an exposure of twenty-four hours to 5 parts per thousand; and after one hour's exposure to 40 parts per thousand, but retained its infective properties after one hour's exposure to 5 parts per thousand.

Tuberculous sputum was disinfected after one hour's exposure to an atmosphere containing 5 parts of chlorine per thousand.

Bacterium of fowl-cholera was destroyed after exposure for twenty-four hours to a moist atmosphere containing 1 part of chlorine in 25,000.

Dr. G. M. Sternberg (*Report National Board of Health*, 1880, p. 320) tested the effect of chlorine upon dried vaccine lymph and the microörganisms of putrid urine. Six hours' exposure of vaccine lymph dried upon ivory points to an atmosphere containing 1 part of chlorine in 200, was sufficient to destroy the infective property of the lymph, as tested by subsequent inoculation. In one experiment, five points were exposed to an atmosphere containing 1 per cent. of chlorine; of these, four were disinfected, while the fifth furnished a satisfactory vaccine vesicle. The failure in this case is explained by Dr. Sternberg by the assumption of an unusually thick coating of dried lymph. In these experiments, control-inoculations with non-disinfected virus from the same packages were made in all cases.

The bacteria of putrid urine were destroyed after six hours' exposure to an atmosphere containing 1 part of chlorine in 400.

Braidwood and Vacher ("Report of Life-history of Contagium," *British Medical Journal*, 1876, vol. ii.) mixed liquid vaccine virus with equal parts of liquor chlori (B.P.), and completely destroyed the infectivity of the vaccine. The time of exposure is not stated.

Dr. E. B. Baxter (*Report of Medical Officer Privy Council*, 1875) tested the effect of chlorine on liquid and dry vaccine, and on the "virus of infective inflammation." The infectivity of the latter was destroyed by the presence of 8 to 15 parts of chlorine in 10,000. The time of exposure to the action of the disinfectant is not stated. The experiments of Dr. Baxter on vaccine lymph are not detailed with sufficient exactness to allow trustworthy conclusions to be drawn. He states, however, that "unless the chlorine was present in sufficient quantity to render the lymph acid, it had no effect."

Fischer and Proskauer, in addition to testing the influence of chlorine on micro-life, also exposed a number of fabrics, colored leather, and wearing apparel to the action of this agent. All the colored articles were either bleached or much altered in color. They conclude their elaborate memoir with the following observation:

Disinfection with chlorine is attended by great inconvenience, on account of the rapid evolution of the gas from the chlorinated lime and hydrochloric acid when mixed, and the very irritant action of the gas upon the mucous membrane of the larynx and of the eyes. Clothing is also liable to be discolored by the action of this disinfectant.

Bromine. — Fischer and Proskauer (*Ibid.*) also studied the effect of the vapor of bromine upon spores of bacillus anthracis, spores of garden soil bacilli, tuberculous sputum, bacillus anthracis, micrococcus prodigiosus, micrococcus tetragenius, micrococcus of erysipelas, aspergillus nigrescens, aspergillus ruber, and several other non-pathogenic organisms.

After an exposure of three hours in a dry atmosphere containing 3 parts of bromine vapor in 100, the anthrax bacillus, tuberculous sputum, and both aspergillus species were entirely disinfected. The spore-bearing organisms and the non-pathogenic micrococci retained their power of development, although generally in a diminished degree. After moistening the air in the experimental chamber to the greatest attainable degree, three hours' exposure to an atmosphere containing 1 part of bromine in 500 acted as a thorough disinfectant; if the exposure was prolonged to twenty-four hours, 1 part in 3500 was efficient. When the proportion of bromine was reduced to 1 part in 16,000, exposure for twenty-four hours failed to disinfect spore-bearing organisms.

Upon the whole, bromine did not prove as prompt a disinfectant as chlorine, besides being very difficult and dangerous to handle.

Iodine.—The disinfecting power of iodine has been determined by Dr G. M. Sternberg (*American Journal of the Medical Sciences*, April, 1883). He experimented upon the micrococci of pus and of septicæmia, bacterium termo, and the organisms found in broken-down beef-tea. An exposure of two hours to the disinfectant in solution, in the proportion of 1 in 500, was effective in destroying the vitality of all of these organisms.

Salmon (*Report of United States Department of Agriculture*, 1883) experimented on the micrococcus of fowl-cholera, and found iodine an efficient disinfectant in the proportion of 1 part in 1000.

Summing up briefly our knowledge upon this subject, the following conclusions seem to be justified:

1. Chlorine is an efficient disinfectant when present in the proportion of 1 part in 100; provided the air and the objects to be disinfected are in a moist state, and the exposure continues for upwards of one hour.

2. Chlorine, when used in sufficient concentration to act as a trustworthy disinfectant, injures colored fabrics and wearing apparel.

3. Bromine is an efficient disinfectant in the proportion of 1 part in 500; provided the air be in a moist state, and the exposure continues for upwards of three hours.

4. Iodine, in solution, is an efficient disinfectant in the proportion of 1 part in 500; the exposure continuing for two hours.

5. The use of chlorine, and in a greater degree of bromine, requires considerable experience in management; when carelessly handled they may cause inconvenient or even dangerous symptoms in persons using them; for these reasons they are not suitable as disinfectants for popular use.

ON SURGICAL TUBERCULOSIS.*

BY R. J. HALL, M.D.,
OF NEW YORK.

SINCE Koch's announcement of the discovery of the bacillus tuberculosis,[1] the medical press has devoted more time to this subject than perhaps to any other in the whole range of medical science. To those who had not followed the steps by which the problem had been brought day by day nearer to its solution, Koch's announcement seemed either an audacious theory, opposed to the results of all previous clinical and pathological research, or a stroke

* An Inaugural Thesis read before the New York Surgical Society, Nov. 11, 1884.

of genius, answering at once the question which had baffled all others.

Many, however, who had followed the subject from the beginning, saw in Koch's discovery but the absolute proof of that which, on other grounds, they had long held to be practically certain.

Although, on account chiefly of the immediate value of the discovery for diagnostic purposes in diseases of the lungs, most of the recent contributions have had reference to cases lying rather in the domain of medicine than of surgery; yet the latter has been by no means entirely neglected. In this country, however, the recognition of the tubercular nature of many surgical affections has been extremely slow. Thus, while so great an authority as Koenig, in Germany, does not hesitate to say that the surgeon, when speaking of chronic inflammation, scarcely thinks of anything but tubercular disease,[2] in an edition so recent as 1883, of a widely read American work on diseases of the joints, tuberculosis is not mentioned as a factor in pathology or etiology; and it is not too much to say that numbers of surgeons of considerable experience never get beyond the terms "strumous" or "scrofulous" in their diagnosis of these same affections.

I do not hesitate, therefore, to present the results of my own examinations of material from cases of surgical tuberculosis with reference to the presence and histological relations of the bacillus. It will be necessary first to sketch briefly the arguments which, in my opinion, render the mycotic origin of tubercle an established fact in medical science, and no longer a mere theory. The subject has been so conclusively dealt with by Koch himself[3] that but little is left except to give a résumé of the argument as presented by him.

The idea that tuberculosis is an infectious disease is by no means new. Klencke, as has been pointed out by Spina[4] and Koch,[5] first successfully inoculated animals with human tuberculosis in 1843. Villemin, however, was the first to attract general attention to the subject by a series of successful inoculations, accompanied by a number of carefully conducted control-experiments, with non-tubercular material, the latter giving always negative results.[6]

At first these views were received with general favor, but soon a large number of experimenters announced that they had arrived at very different results—that inoculations with the most varied non-tubercular animal and vegetable substances, also produced tubercular lesions, especially in animals predisposed to the disease. Among these the reports of Burdon Sanderson,[7] Wilson Fox,[8] and Cohnheim and Frankel[9] may be mentioned as having appeared especially conclusive, and having been most extensively quoted.

When these experiments, however, are examined in detail they are found, as has been well pointed out by Raymond and Arthaud, in an exhaustive article on the subject,[10] to have fallen into errors due to neglect of precautions especially insisted on by Villemin. It is unnecessary now to discuss the cause of failure in those cases in which tubercular material was inoculated and no tuberculosis produced, since not the strongest opponents of the theory of a specific poison would now deny that tuberculosis can be produced by inoculation with tubercular material. In those cases in which it had been alleged that tuberculosis has been produced by inoculation with indifferent non-tubercular substances, the observers have sometimes trusted to the macroscopic appearances, calling any nodules found on autopsy of the animals experimented on tubercles. In this way the nodules in the livers of rabbits due to the eggs of strongylus, tænia, and other parasites, and so common that in three hundred otherwise healthy rabbits examined by Raymond and Arthaux,[11] almost all contained them, have undoubtedly been taken for miliary tubercles; and the same has probably been the case with small foci of broncho-pneumonia and miliary abscesses in the lungs in experiments by inhalation. Or, the observers have depended on an insufficient histological examination of the inflammatory products; or, perhaps, the most frequent error of all, they have operated with a total neglect of all precautions in selecting healthy animals, having clean knives, hands, and operating rooms, keeping the animals separated from others already infected and under good hygenic conditions. No single observer has yet inoculated animals with non-tubercular material, using the necessary precautions mentioned above, produced a progressive tuberculosis, and *proved that it was tuberculosis by further inoculations* in series on other animals; yet nothing less than this would be necessary to outweigh the overwhelming evidence on the other side, for all this can be accomplished with certainty by the use of tubercular material. It is important, also, to note that Cohnheim, feeling doubtful of the reliability of his own experiments in the crowded and dirty laboratories in Berlin, repeated them in Breslau, with proper precautions, using chiefly the anterior chamber of the eye for inoculations, and with entirely opposite results, producing tuberculosis invariably with tubercular material, and never with any other;[12] and recently Dr. Dawson Williams, at the request of Drs. Sanderson and Wilson Fox, repeated their experiments, using every precaution against accidental infection, and also with entirely negative results. These experiments were controlled by Dr. Wilson Fox himself, who was present when Dr. Williams read his paper.[13]

Among many others who have made extensive observations, with the same results, may be mentioned H. Martin,[14] P. Baumgarten,[15] K. Schuchardt,[16] Damsch,[17] Tappeiner,[18] Dieulafoy et Krishaber,[19] and Koch himself.[20]

Having been led to the conclusion, on the above and other grounds, that tuberculosis was possibly due to a specific poison of a parasitic nature, the steps pursued by Koch,[21] as described by himself, were as follows: First, to determine whether in tubercular tissues elements occurred foreign to the tissues and not produced by them; second, having found such elements, to prove that they were living organisms, which could be distinguished from others of the same family, and capable of indefinite multiplication; third, to show that tissues containing these organisms, as we may now call them, when used for inoculation produced the disease, and that no other tissues

did so; fourth, to cultivate these organisms on suitable soil and with suitable precautions against contamination, through successive generations, until it was absolutely certain that none of the original material was present, and with these pure cultures to produce the same disease; and, lastly, to show by a sufficient number of control-experiments that inoculation with indifferent substances never does produce tuberculosis. All this has been accomplished by Koch with marvellous accuracy and minuteness of detail, in such a way as not to leave a loophole of escape from his conclusions. His experiments and observations extended over hundreds of cases, with the most uniform results. As has been well said by a recent reviewer, "It is fair to predict that among the future assailants of Koch's work, there will be very few men of judgment who have read the work in the original."[22] As for the various attacks that have been made upon Koch, they have been so conclusively answered by himself that it is scarcely necessary to do more than refer to his own article in answer to his opponents.[23]

It is worthy of note that among the numerous adverse critics, with the exception of some quite inconclusive inhalation-experiments by Balogh[24] and Schottelius,[25] only two, Spina and Formad, claim to have repeated Koch's work. Spina's[26] two or three experiments fail so utterly to comply with the conditions necessary in such an investigation as to be absolutely puerile, and quite worthy of the contempt with which Koch treats them. While I cannot discover that Formad has made any experiments on the subject, except those implied in the statement[27] that almost all animals in laboratories acquire tuberculosis, no matter what operation has been performed on them, this, in the present state of scientific knowledge on the subject, produces, as a critic has remarked, somewhat the same effect on the mind of the reader as if a surgeon should say that pyæmia could not be due to a specific poison, because all the patients operated upon in his wards died of it. It is, perhaps, of purely historical interest that while Formad gives abnormal narrowness of the lymph-spaces as one of the anatomical causes of tubercle, Hunter had already suggested an abnormal wideness of the lymphatic system as the probable cause of the same.[28]

Assuming, then, as proved, the etiological relation of the tubercle bacillus to tubercular processes, let us consider what interest this has for surgeons. From a pathological point of view, the identity of the inflammatory products in the more important surgical diseases with the pulmonary tuberculosis of Bayle and Laennec, was very early recognized. Delpech[29] maintained the tubercular nature of Pott's disease, as did Nichet[30] very shortly after the publication of Laennec's views. Nichet also described cold abscesses, independent of bone disease, formed by the confluence and breaking down of tubercle. Nélaton,[31] in 1836, describes tubercular osteitis, encapsulated and diffuse, its various terminations and the ways in which it affects the joints, almost as minutely as Koenig has done recently, in his admirable monograph on the subject.[32] All these investigations, however, were founded chiefly on the macroscopic appearance of the miliary tubercle. It was not until the description of the giant cell by Langerhans,[33] and the demonstration of epithelioid cells, surrounded by a fine reticulum, and forming a nodule, enclosing usually one or more giant cells, by Schüppel[34] gave a firm anatomical criterion for the diagnosis, that exact investigations could be made. Then followed the demonstration of tubercular disease in almost every tissue and organ of the body. Among the most important from a surgical point of view, the following may be mentioned: K. Köster,[35] in 1869, founding his conclusions on a careful examination of nine cases, first described miliary tubercles as a constant occurrence in fungoid joint diseases. Ranvier[36] had already described tubercular osteitis. Friedländer[37] found tubercles in caries of bone in scrofulous skin diseases, lupus, the os uteri, the wall of a mammary cyst, and other unexpected places. Schüppel,[38] in 1871, described tubercular lymphadenomata so minutely that pathologists have had scarcely anything to add and nothing to alter since, and declared the tubercle-like lymphadenomata of E. Wagner[39] to be really tubercle. Köster[40] found tubercles in fungoid osteitis and osteomyelitis, independent of joint disease, in almost every portion of the male and female genito-urinary tracts, in the larynx, the mamma, and the tongue. R. Volkmann,[41] in 1879, and Lannelongue,[42] in 1880, described in detail the tubercular character of cold abscess, the latter including those not dependent on tubercular disease of bone. G. Feurer[43] examined twelve cases of vertebral caries, and found nine certainly, the remaining three probably tubercular. Koenig[44] has recently called renewed attention to the frequently tubercular character of the common chronic hydrops of joints and sheaths of tendons, in the latter especially when accompanied by rice bodies, and also of some fibrous foreign bodies in joints. The joint affections had already been carefully studied by Riedel,[45] but in the increasing scepticism, as to the common origin and pathological importance of tubercular products, had been almost completely lost sight of. Bizzozero,[46] in 1874, described tubercular disease of the skin, of the sheaths of tendons, and other regions. K. Ohnacher[47] has recently published two cases of tuberculosis of the mamma with great detail, and a complete account of all previously observed cases. Nedophil,[48] though by no means the first, has discussed tubercular disease of the tongue more fully than any other author. For a more complete literature, I would refer to the works of Virchow[49] and E. Aufrecht[50] for the older observations, and to the elaborate articles of Neisser,[51] Mögling,[52] and Charvot[53] for the more recent. In spite, however, of the enormous amount of work done in this direction, the absence of what could be considered as direct proof of the etiological unity of all tubercular products made it difficult to draw any very practical conclusions from the knowledge obtained, and many of the authors mentioned above considered the frequency with which tubercle could be demonstrated in diseases clinically so utterly unlike as the strongest argument against the theory of its specific character. Rindfleisch's view, so widely accepted, of tubercle as merely an ordinary inflammatory process, modified by the constitution

of the individual in whom it occurred, and the great authority of Virchow,[54] who, defining tubercle as a neoplasm, and scrofula as an inflammatory process, running a peculiar course from local or constitutional causes, affecting the nutrition of the part, designated a very large proportion of surgical tuberculoses as scrofulous, tended to deprive these observations of their true importance.

In 1878 Volkmann's[55] article, "Über den Charakter und die Bedeutung der Fungösen Gelenkentzündungen," appeared. Founding his conclusions on examinations made by himself and his assistant, Friedländer, he declared the whole class of fungoid joint diseases, caseous lymphomata, cold abscesses, scrofulous ozæna, many rectal fistulæ, and obstinate ulcers of mucous membranes and of the skin, to be tubercular. He accepted fully Villemin's theory, which has been so much disputed, of the specific character of tubercle, and pointed to the frequent infection of all the parts surrounding a tubercular centre as most strongly confirmatory of this. Acting upon these views, he advocated the complete extirpation of all tubercular material, wherever accessible, as the only reliable means of curing the local disease and guarding against general infection. Heuter[56] had already advocated the same principles with great earnestness, though with less clear views as to the nature of the pathological processes; and Koenig, as he himself informs us in the dedication of his monograph already mentioned, while on a visit to Halle some twelve years ago, became an enthusiastic convert to the doctrines of his friend Volkmann. Under the guidance of these three great men German surgeons accepted the new teaching almost universally, and applied it so widely in operative practice as to have brought about at the present day a quite decided reaction. In France, however, it found few adherents; this is well illustrated by a discussion[57] of the subject as applied to diseases of the joints so late as 1882, in which many of the prominent French surgeons took part, and Lannelongue, whose work has been already referred to, almost alone supported the German opinion. In England and America, a reference to almost any of the most recent surgical works will show that it can scarcely be said to have made progress at the present day.

Even in Germany dissenters were not wanting among surgeons; Lücke, in 1880[58] and 1881,[59] denied the etiological unity of the chronic bone diseases in which the histological tubercle is found, attributing them to five different causes, as follows:

1. Hereditary and acquired tuberculosis and scrofulosis; 2. Hereditary and acquired lues; 3. Former attacks of infectious diseases, as pyæmia, osteomyelitis, typhus, etc.; 4. Trauma; 5. Gout.

And Sonneburg, in 1881,[60] headed what promised to be a formidable revolt among the younger men against the specific theory, had not Koch's discovery so shortly afterwards, afforded the means of placing it in an unassailable position.

In Koch's earliest publications on the subject, already referred to, the occurrence of the bacilli in surgical tuberculoses was demonstrated, and the extraordinarily small number in which they are usually found was noticed. Shortly afterwards more extensive observations were published by Schuchardt and Krause,[61] showing, on the evidence of a large number of cases, the constant occurrence of the bacillus. It will be more convenient to give the particulars of these and other reports later, when discussing the tuberculoses of different regions.

The technique of the examination may be considered under the following heads: 1. The selection and presentation of material, cutting, staining, and mounting. 2. Apparatus necessary for making the examinations and mode of examining.

1. It is almost unnecessary to say that only material should be selected containing the well-known gray gelatinous tubercle, usually dotted with small caseous specks. As this is difficult to recognize after immersion in alcohol, the selection should be made before hardening, or much time may be wasted in cutting. It is best to place the specimen directly in absolute or ninety-five per cent. alcohol, and cut as soon as it is sufficiently hard. Müller's fluid can be used,[62] but has no advantages, except the clearer demonstration of the tubercle reticulum,[63] while the granular precipitates to which it gives rise in the tissues interfere more or less with all mycological examinations.[64] Commencing putrefaction does not prevent the demonstration of the bacilli, and they can be found even in old alcoholic preparations [65] On account of the very small number of bacilli found in most cases of surgical tuberculosis, it is usually necessary to examine a number of sections, and it is very desirable that they should be moderately thin and of even thickness throughout. A good section-cutter is, therefore, almost an essential, and I have used always the largest size made by Jung, of Heidelberg. The staining of the tubercle bacillus depends, as is well known, on the fact that after staining the object to be examined in a solution of one of the aniline dyes, usually fuchsine or gentian violet, made in a particular way, it can be decolorized by the dilute mineral acids and alcohol, when only the tubercle bacillus retains its color. The specimen can then be stained with a contrast-color, as methyl-blue for fuchsine, and Bismarck brown for gentian violet. This makes it easy to study the histology of the tissue, and forms a background on which the bacillus stands out more distinctly. There are a number of theories of the cause of this peculiar reaction of the tubercle bacillus, but none are at all satisfactory, and they need not detain us. Koch himself has discarded his original method of staining, and I will, therefore, not stop to describe it.

I have used altogether Ehrlich's method, which, with more or less modification, has been employed by almost all observers. My exact procedure has been as follows: To distilled water so much aniline oil is added that, after shaking vigorously, some still remains undissolved. This is allowed to stand for a few minutes, being shaken at intervals, and then passed through a moistened filter, when a clear fluid should be obtained. To this is added, drop by drop, a saturated alcoholic solution of fuchsine or gentian violet, until a metallic shimmer appears over the whole surface. In this staining fluid the sections are immersed for twenty-four hours. Fluids are spread in thin layers upon cover glasses, allowed to dry, passed three times moderately fast, with the smeared

side upwards, through the flame of an alcohol lamp or Bunsen burner, and then floated on the fluid for the same length of time. At a temperature of about 50° C., one hour is sufficient;[66] but I have found it more convenient, and think it surer, to keep them twenty-four hours. They are then tranferred directly to thirty per cent. nitric acid for a few seconds, washed for a few seconds in about sixty per cent. alcohol, and then stained again in a solution of methyl-blue or Bismarck brown, made by adding a saturated alcoholic solution of the coloring matter to distilled water, until the liquid begins to lose its transparency. The specimens remain in this for from five to ten minutes, are then washed in dilute alcohol, dehydrated in absolute or ninety-five per cent. alcohol, cleared in oil of cloves* and mounted in Canada balsam. These rules are identical with those most recently given by Koch,[67] except that he uses nitric acid, one part to three or four parts of water, leaves the specimens in the staining fluid twelve hours as the minimum, and gives exact proportions for making the staining fluids, and these changes are, I have no doubt, improvements. In my earlier work, I met with certain difficulties which it may be well to mention. Almost all the descriptions which I had at that time read spoke of the necessity of completely decolorizing the specimen in the acid. This I found to be quite impossible after the sections had been twenty-four hours in the staining fluid. Even after twenty-five minutes in the acid, a considerable amount of color remains in the tissues; it is, however, completely removed by the alcohol. There does not seem to be much danger of bleaching the bacilli by the acid, if the section has been stained during twenty-four hours, as I have found them very abundant in specimens which had been twenty-five minutes in thirty per cent. nitric acid. There is, however, great danger of decolorizing partially or completely, some or all, of the bacilli, when stained by any of the short methods, so useful for examining sputum. I would, therefore, strongly advise against the use of any of these short methods in surgical cases, in which it is to be expected that the bacilli will only occur sparingly, and, if but faintly tinged, may be obscured by the cells among which they lie. Koch directs, as a precautionary measure, that the specimens should only remain a few seconds in the acid. It is important that the specimens should not be immersed in water at any time after staining, as this fixes the remaining color, and makes it difficult or impossible to remove with alcohol; in this way other objects besides the tubercle bacilli may retain the characteristic color, and this has doubtless given rise to many errors The thirty per cent. acid used to decolorize, besides being disagreeable to manipulate, sometimes shrinks the tissues to an inconvenient extent; the more dilute solution recently recommended by Koch is therefore an improvement, and he suggests that it may be safe to dilute it even more. I have found, however, in decolorizing with merely slightly acidulated alcohol, as recommended by Orth, the nuclei of some cells, and particularly the granular protoplasm of Ehrlich's mastzellen, are liable to retain the violet stain, and indifferent bacilli might possibly do the same. Horny constituents of the tissues retain the color, and fragments of this kind, such as hairs and horny epithelium, may give rise, if the fact is not known, to a suspicion that the specimen has been insufficiently decolorized. Almost all these points are discussed by Koch, whose last article on the subject I had not been able to see until after I had worked them out for myself. In accordance with most other observers, I have found gentian violet and Bismarck brown much the most satisfactory staining. Violet has indeed the disadvantage of not showing well by artificial light, but by daylight the bacilli stand out rather better than when stained with fuchsine. Bismarck brown, also, I have found more manageable as a contrast-color than methyl-blue; there is, I think, less danger of overstaining, and any superfluous color can be more readily washed out in alcohol. The lepra bacillus, as is well known, alone of all hitherto known varieties, stains in the same manner as the tubercle bacillus. It differs from it, however, in shape and size, as well as in coloring by Weigert's method for nucleus staining, and there is little practical danger of confounding the two. Considering the rather complicated technique, it is not strange that a small number of observers have reported that bacilli other than the tubercle and lepra varieties take the characteristic color. In one instance in which Craemer[68] reported the discovery of tubercle bacilli in the stools of healthy persons, Marchand[69] examined the specimens, and states that all bacilli were stained, the preparations being insufficiently decolorized. There is such a mass of reliable evidence on the other side, that it is fair to conclude that the remaining cases rest on similar errors. I have myself frequently examined decomposing urine, sputum, and pus, and once or twice tissues, in which putrefaction had commenced before immersion in alcohol; all these were swarming with microörganisms, stained brown, but I have not found any stained violet, whose shape, or size, or situation would suggest that they were not tubercle bacilli.

2. The tubercle bacillus can be seen with a power of about 300 diameters, but Koch recommends 500 to 700 as best. For the examination of fluids spread on cover-glasses, an ordinary microscope can be used. For the examination of sections, however, the addition of a good Abbe condenser, used without a diaphragm, is necessary. With this the outlines of the tissues are almost completely lost, and scarcely anything is seen in the field except the stained bacilli and the nuclei stained with the contrast-color. The Abbe is so essential that I would not attach any importance whatever to a diagnosis made by myself or any one else without its aid. It is true that in a section rich in bacilli it is possible to see a few, using a high power without the condenser. But were they not known beforehand to be bacilli, it would often be impossible to assert it with confidence, while the greater number escape observation altogether. Koch insists also on the importance of using a homogeneous oil immersion. Having been disappointed in an effort to get one, I have been compelled to use a very good Hartnach water immersion, No. 10, after first convincing myself by a number of trials that the bacilli could be very well seen with it. I have

found, however, where the tissues were deeply stained or the sections at all thick, some difficulty in penetrating them with the water immersion, and I have no doubt the oil system would have saved much time. In surgical tuberculoses, in which the bacilli generally occur very sparingly, they are usually in the giant cells. It is best, therefore, as pointed out by Schuchardt and Kraase, to pick out a giant cell and then examine it thoroughly with the immersion system, going on to another only when convinced that the first conceals no bacilli.

I shall give the results of my own investigations in the following order:

I. Tubercular disease of bones and joints.
II. Tubercular lyphomata.
III. Tubercular disease of the skin.
IV. Other tuberculoses.

Adding to each group such remarks as are necessary, and giving at the end the principal observations already published.

I. Tubercular Disease of Bones and Joints.

Case I. *Fungoid Arthritis of Wrist, with several Sinuses.*—Man, æt. 35, family history of phthisis. States that he sprained his wrist thirteen months ago; that an abscess formed within a week, and was opened four weeks later. Excision February 9, 1884. Microscopic examination of sections of granulation-tissue on carpal bones shows hyaline cartilage, the cartilage-cells proliferating, and granulation-tissue containing a few cartilage-cells, without capsules, and at one point commencing to undergo change into cicatricial tissue. In the granulation-tissue there are a few tubercles, containing giant cells, and in some cases caseous in the centre. Four specimens examined: fuchsine; no double staining; two negative; in two a small number of bacilli.

Case II. *Cold Abscess of Knee-joint.*—Adult man; disease of spine of many years' duration; joint distended with fluid; no sinuses. January 15, 1884, joint incised, and sero-purulent fluid, with large masses of fibrin infiltrated with pus, evacuated. Examination of sections of fibrin: fuchsine; five specimens; three negative; two contain a very small number of bacilli. March 19, 1884, excision of the joint. Microscopic examination of the thin layer of tubercular tissue lining the whole interior of the joint shows abundant tubercles, containing giant cells and cartilage invaded by granulation-tissue. Three specimens: violet and brown; two negative; in one a few bacilli; five or six in all, one in a giant cell, one close to, but apparently not in, a giant cell; the remainder on the borders of caseous material.

Case III. *Fungoid Arthritis of the Shoulder-joint.*—Adult man; disease has existed more than six years; abscesses have formed and broken in the neighborhood of the joint, and sinuses remain open. Excision May 15, 1884. The cartilage is found to have disappeared from the head of the bone, which is in part covered by fungoid granulations, in part bare and carious. There is a large sequestrum lying loose in a cavity in the head of the bone. Gross appearance of the granulation-tissue is that of gray gelatinous granulations, with numerous white specks; caseous material throughout. Microscopic examination shows numerous tubercles, most of them containing one or more giant cells, and showing advanced cheesy degeneration in places. Five specimens: violet and brown; two negative; in one, five bacilli in a tubercle among epithelioid cells; in another, one bacillus in a giant cell; in a third, three giant cells contain each a bacillus.

Case IV. *Fungoid Disease of the Tarsal Bones.*—Man, æt. 33; family history good; duration of the disease, four years; abscesses formed eight weeks ago. April 28, 1884, amputation of leg. There is extensive fungoid caries of the astragalus, scaphoid, and cuboid. Gross appearance of the fungoid tissue the same as in Case III. Microscopic examination shows granulation-tissue, with a border of young epidermis at one point, and containing numerous tubercles with many giant cells. Five preparations: violet and brown; three negative; in two, one giant cell in each contains a bacillus.

Case V. *Fungoid Disease of (probably) Sacro-coccygeal Articulation.*—Man, æt. 34; family history good; general health good; lungs normal. Two months ago, small abscess to left of coccyx; broke in a few days, and pus, with small fragments of bone, evacuated. Sinus has remained open, and leads to an articulation, apparently that between the sacrum and coccyx. Sinus lined with fungoid granulations. May 16, 1884, resection and scraping. Microscopical examination shows typical tubercles. Five specimens: violet and brown; four negative; in one a miliary tubercle contains three bacilli, one in a giant cell, two among epithelioid cells; two other miliary tubercles contain two and one bacilli, respectively, close to, but apparently in, giant cells.

Case VI. *Fungoid Disease of the Knee-joint.*—Young man; duration of disease unknown: numerous sinuses exist, and joint is much disorganized. Excision May 24, 1884. Fungoid granulations line the whole interior of the joint. No tubercular osteitis observed, and disease probably of synovial origin. Microscopical examination shows typical tubercles. Eight specimens: violet and brown; five negative; three contain one bacillus each, among epithelioid cells.

Case VII. *Fungoid Disease of the Ankle-joint.*—Boy of about 17: duration of disease unknown; joint has been incised and drained, and sinuses remain open, and are lined with fungoid granulations. Excision May 22, 1884. Gross and microscopic appearances as in last. Five specimens: violet and brown; two negative; one contains three bacilli, and two others one each. All the bacilli are close to giant cells, and in or among epithelioid cells.

Case VIII. *Fungoid Disease of Ankle-joint and Tarsal Articulations.*—Man, æt. about 22; disease probably primarily synovial; suppuration had occurred and incisions had been made; sinuses remain open. Mikulicz operation June 4, 1884. Gross and microscopic appearances as in Case VI. Five preparations: violet and brown; three negative; in one, two bacilli; in another, one.

Case IX. *Suppurative Arthritis of Shoulder-joint, following Drainage of a Large Hygroma.*—Man, æt. 48. The hygroma, just in front of the anterior border of the deltoid, was first noticed nine weeks ago, and

then nearly as large as when incised; had been tapped twice. Incised March 11, 1884, when fluid containing rice bodies and disorganized tissue, like cartilage, evacuated. Joint entered, and articular surfaces found eroded. Excision June 9, 1884. The head of the bone was denuded of cartilage, carious, and covered in part with gray gelatinous granulations, containing, however, none of the white caseous specks. Portions of the granulation-tissue from the cavity of the joint present a similar appearance, but dotted with a small number of white specks. On microscopic examination, a large part of the section shows only granulation-tissue and young connective tissue; a portion consists of non-vascular tissue, formed principally of epithelioid cells, with a few giant cells, and at points commencing cheesy degeneration. On the borders are a few miliary tubercles, some becoming fibrous. Six specimens examined: violet and brown; four negative; in one, one bacillus in a giant-cell; in another, two bacilli close together.

CASE X. *Fungoid Disease of the Hip-joint.*—Girl of about five; both femur and acetabulum extensively involved, and sinuses exist; excision, June 18, 1884. Both gross and microscopic appearances of the granulations are those of tubercle tissue. Two specimens examined: violet and brown; several bacilli found in each; two in one giant cell.

These are all the cases of tubercular arthritis and osteoarthritis which I have examined, and, as seen, bacilli have been found in all; though in some cases only after a prolonged and careful examination, extending even over several hours. Even at the risk of being tedious, I have given these cases in some detail because, although few in number, they afford examples of each of the three forms of joint tuberculosis as classified by Koenig,[70] and even of several of the anatomical varieties included in these. Koenig's classification is as follows: 1. Hydrops tuberculosis; 2. Fungus tuberculosis, granulating fungoid inflammation of joints, tumor albus; 3. Cold abscess of joints.

Case IX. is a good example of the first class, which Koenig says is the form "relatively infrequent and still least known to the surgeon," and of which he gives the first really complete clinical description. It is also, as far as I know, the first case of this kind in which the bacilli have been demonstrated. We have in it, further, the extremely instructive combination of a large bursal hygroma, containing rice bodies, with a tubercular arthritis, the hygroma communicating with the joint. The recognition of these cases by Riedel, and recently by Koenig, has been referred to already.

Most of the remaining cases come under the head of (II.) fungus tuberculosis proper, by far the commonest form. Case III., in which a large sequestrum occupied a cavity in the head of the humerus, is a beautiful example of that variety in which a circumscribed tubercular osteitis gives rise to a limited necrosis immediately beneath the articular cartilage, and involves the joint secondarily. Koenig suggests, on account of the frequent wedge-shape of the sequestrum, that it is probably due to an embolic process. In such cases, as the sequestrum can be neither absorbed nor eliminated, it is obvious that operation offers from the very first the only prospect of cure. Unfortunately, it is very seldom that the state of affairs can be appreciated until the joint has been laid freely open. Several of the cases presented small cavities in the articular ends of the bones, filled with caseous material, indicating the probable origin of the disease in a circumscribed osteitis, causing the complete disintegration of the bone, and involving the joint secondarily as before. Case IV., in which the astragalus, scaphoid, and cuboid were all extensively diseased, is a good example of the infiltrated tubercle, where the disease rapidly involves the whole epiphysis or short bone, as the case may be, and produces complete disorganization of the neighboring joint. Such cases, which are fortunately not the most common, usually, as in the above, demand amputation. Cases VI. and VIII. were probably of synovial origin, as no tubercular osteitis could be found. Volkmann[71] declared this to be extremely rare, the disease beginning usually, and in children practically always, "so gut wie ausnahmslos," in the bone. Further observations, especially by Koenig, and by Müller[72] under Koenig's direction, have shown that although much the less common, the synovial origin is not so infrequent as Volkmann supposed, being in fact about 20 per cent. of all cases.

Finally, Case II. is a good example of (III.) cold abscess of the joint, or synovitis suppurativa tuberculosa, as Koenig prefers to call it, in which the interior of the capsule is lined with a tubercular membrane, and the joint distended with the characteristic tubercular pus.

II. Tubercular Lymphomata.

CASE I.—Anæmic, but otherwise robust young man. Lungs apparently sound. Cervical and axillary lymphomata of two years' duration. Partial extirpation February 19, 1884. Microscopic examination shows large-celled infiltration, abundant miliary tubercles, containing giant cells and advanced caseous degeneration in parts. Four specimens: violet and brown; three negative; one shows a considerable number of bacilli on borders of a caseous mass.

CASE II.—Man, aged 21. Cervical lymphomata of six years' duration. Extirpation April 15, 1884. Microscopic examination shows large caseous masses in all the glands, and immense numbers of miliary tubercles, containing generally one to three giant-cells. Three specimens: violet and brown; one negative; in one, three bacilli in one giant cell; in another section, one bacillus in a giant cell, and one among epithelioid cells.

CASE III.—Young man. Cervical lymphomata. Extirpation June 18, 1884. Microscopic examination shows glands to be almost entirely caseous; only at borders of the glands are a number of typical tubercles, almost all caseous in the centre, and most containing a giant cell. Three preparations: violet and brown; one negative; in one, six bacilli together, among epithelioid cells; in another, two giant cells contain each a bacillus.

In a fourth case, in which cervical lymphomata presented the typical tubercular structure, no bacilli were found in the three sections examined, but as

they were found in sections of a tubercular cervical ulcer, excised from the same patient, the search was not continued.

Mögling, in his discussion of chronic lymphomata, quotes Ziegler's classification as follows:

1. The small-celled hyperplasia, undergoing caseation or suppuration. 2. The large-celled indurated hyperplasia. 3. The reticular hyperplasia. 4. Tuberculosis, and the more complicated and less satisfactory arrangement of Orth.

He shows that Group 2, in the above, is undoubtedly to be considered as tubercular, both from the anatomical structure and the fact that Dr. Nauwerck, and Mögling himself, have demonstrated the bacilli in glands of this structure, but leaves it doubtful whether those in the first group, which undergo cheesy degeneration, do not belong to the same category. The four cases given above all presented the classical tubercular structure described by Schüppel, namely, groups of epithelioid cells enclosing more or less numerous giant-cells. To these may be added a fifth, not of a surgical character.

5. Mesenteric lymphatic glands from child dead of tuberculosis of the lungs, liver, and mesentery. Mesentery studded with miliary tubercles. Microscopic examination. Almost the whole gland caseous; at the borders a few tubercles, most of which are fibroid. Here and there groups of lymphoid cells, not yet cheesy. Three specimens: two negative; in one, four bacilli, lying among lymphoid cells.

These cases, therefore, only furnish additional evidence, if such were needed, that all lymphomata possessing this characteristic structure are due to the invasion of the tubercle bacillus. The further question raised by Mögling, whether any other than these are due to the same cause, has been practically settled by Koch[73] himself, who, after demonstrating the bacilli in all cases, twenty-one in number, having the tubercular structure, failed to find them in any of a number which were enlarged, in some cases softened, and containing small collections of pus, but which did not show the collections of epithelioid and giant cells. Here, then, as elsewhere, we may rely confidently on the histological structure for a diagnosis.

III. Tuberculosis of the Skin.

Case I. *Tubercular Ulcer of Thorax.* — Man, about twenty-five, with remarkably long, flat thorax; superficial ulcer, about two and a half inches in diameter, over the upper portion of the sternum, with eroded, undermined edges, constantly spreading by erosion of the margins; surface covered with small granulations, which have a great tendency to break down. Patient has acute phthisis, the whole of the right and a great portion of the left lung being involved. No appetite; hectic and constant cough, with very abundant purulent expectoration. States that these symptoms have only existed a few weeks, and appeared after the ulcer. Examination of the sputum: fuchsine; a small number of bacilli. Examination of material obtained by scraping: eight preparations; fuchsine; six negative; four bacilli in one, and one in another.

Case II. *Tubercular Ulcer of Sac.*—Young man with tubercular cervical lymphomata (see Cervical Lymphomata, Case IV.), and ulcer of the neck, which was excised. Microscopic examination of sections made through the base of the ulcer shows typical tubercles containing giant cells. Twelve specimens: fuchsine; eight negative; two contain each a small number of bacilli, and two a very few.

Case III.—Caspar Docrr, æt. 52, Feb. 14, 1884. Family history and general health good. One year and eight months ago small papules appeared on dorsum of left wrist; these coalesced, forming a patch, which spread at the margins, not itching. Just before admission, acute lymphangitis, extending from the wrist to the axilla, where lymphatics are enlarged and painful. Examination: There is a papillary growth on the dorsum of the wrist, but slightly elevated above the surface, squamous at the edges, of irregular, oval shape, about four inches long, and extending slightly on the dorsum of the hand. Tissues boggy, and pus can be squeezed out between and from beneath the hypertrophied papillæ; there are irregular, isolated papules around the margins, showing the orifices of a few sebaceous follicles, from which pus and cheesy material can be squeezed; ether was administered, and the parts thoroughly scraped with a sharp spoon, which readily penetrated to the fascia, through tissue resembling soft granulation-tissue commencing to break down. Lymphadenitis subsided promptly and surface cicatrized.

September 12th: seen a few days ago, when cicatrix was firm and healthy. There are a few papules resembling lupus nodules around the margin. Microscopic examination shows hypertrophy of the papillæ, with rapid proliferation of the epithelium, forming numerous nests. Papillæ infiltrated with small, round cells, and in parts transformed into granulation-tissue; no tubercular tissue seen. Seven sections examined: fuchsine; all negative.

Case IV.—Woman, æt. 58; March 18, 1884. About one year ago noticed a small pimple on the back of the left hand. This gradually enlarged, and about two months ago began to discharge a seropurulent fluid. Examination: There is a patch, the exact counterpart of that in the last case, except that the lymphangitis is absent; it is elliptical, two by two and a half inches in diameter, situated on the outer part of the dorsum of the left hand, just above the fourth and fifth fingers; ether; surface scraped with sharp spoon, presenting precisely the same characteristics as Case III.; cicatrized rapidly. Microscopic appearances precisely similar to Case III., except that epithelial pearls are much less abundant.. Five preparations: all negative.

I have thought these two cases of sufficient importance to be given in detail, although no bacilli were found in them, because, occurring in advanced adult life, they presented very exactly the features of lupus verrucosus or papillaris, combined with those of the scrophuloderma of Neisser, or tubercular gumma of Deprès. Unfortunately, trusting to the microscopic examination, no inoculations were made, and, having only scrapings to deal with, it was almost impossible to find fragments from which sections

could be cut, and those obtained showed only hypertrophied papillæ and proliferating epithelium, in which I could not expect to find bacilli. The clinical diagnosis, however, acquired greater certainty from a third case, presenting many points of great similarity, as follows:

CASE V. — James McMullen, æt. 53. May 17, 1884. Family history good; general health good until about six years ago, when left forearm was amputated for chronic suppurative disease of the wrist-joint, occurring without known cause. Two years ago a small red pimple appeared on dorsum of right hand; itched much, and spread in all directions. At first dry and scaly; surface became moist; healed in the centre and spread at the edges. With various salves portions of the edges healed, leaving patches on the dorsum of the metacarpo-phalangeal articulations and radial margin of wrist, as at present; ceased to itch after a time. Three months ago the whole ulnar half of the dorsum of the wrist, hand, and lower two inches of the forearm became red, swollen, and painful; and two months ago a number of openings formed spontaneously and discharged pus; have remained open since.

Examination: There are horny papillomatous patches on dorsum of metacarpo-phalangeal articulation of thumb, index, fourth and fifth fingers. Surface is dry, horny; margins dull-red; patches slightly elevated; blunt end of probe readily penetrates the tissues. Over the first carpo-metacarpal articulation is a red, slightly elevated, elliptical patch, one by one and a half inches in diameter, dry and slightly scaly on the surface, exactly resembling lupus exfoliativus. This has shifted from the dorsum of the hand, leaving the skin behind it white and atrophied; whole unaffected portion of dorsum of hand where the disease has been is thin and atrophied. The portion of the wrist and hand described above as the seat of inflammation during the last three months is red, boggy, and slightly swollen. On ulnar margin of wrist are two small openings, through which a probe can be passed in all directions under the skin, and sero purulent fluid escapes; all the skin involved, though dry and covered by cuticle, can readily be penetrated by the probe; scraped thoroughly with sharp spoon, and operation repeated shortly afterwards; condition much improved, although several sinuses remain open, and there is still a good deal of infiltration of the tissues. Inoculation on July 2d of guinea-pig, subcutaneously in abdomen, with material obtained by scraping; Koch's syringe used, and careful antisepsis. Two days later control-inoculation of another guinea-pig in same manner, with indifferent material. September 1st guinea-pig killed; inguinal glands and one lying on common iliac artery on inoculated side enlarged to size of beans, caseous throughout, and broken down in the centre. No other tubercular lesions found; control guinea-pig healthy, and inguinal glands not enlarged. Examination of caseous substance from glands (violet and brown staining) shows large numbers of bacilli, almost all containing spores, and well developed.

In addition to these cases, I must mention that an intraperitoneal inoculation of a guinea-pig with lupus vulgaris of the face failed entirely. Neisser,[74] in his most valuable and elaborate article on tuberculosis of the skin, classifies them as follows:

1. Tuberculosis in the narrower sense, with the formation of ulcers situated in the cutis, and of miliary tubercles, as part of a general tuberculosis.

2. Lupus, a less harmful variety of tuberculosis, generally remaining limited to the skin.

3. Scrophuloderma ulcerosum—*i. e.*, ulcerations which remain after the evacuation of the so-called subcutaneous cold abscesses.

Mögling objects to this classification on logical grounds, since all being tuberculoses it is not well to apply this name, which properly belongs to the whole class, to a single variety; and points out that, by this arrangement, we have the ulcers extending from tubercular lymphomata under the scrophulodermata, while those originating in tuberculosis of the bones of the skull are considered true tuberculoses. The objections to this classification are well illustrated by the following case:

Man, æt. 21; father died of consumption five years ago. Patient has cervical tubercular lymphomata of eight months' duration, and advanced acute phthisis, symptoms of two months' duration. Sputum is very abundant, and contains immense numbers of bacilli. About four months ago, a small lump appeared just below the inner third of the right clavicle, softened and broke, discharging white matter, and leaving a superficial ulcer, now almost exactly similar to that in Case I. Comparing this with the ulcer of the thorax, described above, we have two lesions, anatomically precisely alike, occurring in patients about equally advanced in acute pulmonary tuberculosis; but the one which commenced as an abscess, classified as scrophuloderma; the other, which was an ulcer from the beginning, as tuberculosis.

Mögling himself suggests the following division, taking the etiology as the principle of classification:

1. Primary tuberculosis of the skin.

A. Lupus.

B. Tubercular ulceration and pachydermatous infiltration (pachydermie).

2. Regional tuberculosis, extending to the skin.

3. Metastatic tuberculosis.

To this, there are still graver objections than to Neisser's. The term metastatic, applied to one subdivision, implies that no other variety can originate in that way. But this, it is scarcely necessary to point out, is a pure assumption. It is, indeed, true that since the tubercular character of lupus has been recognized it has been very generally treated as probably due to a local infection from without. There is, however, not a particle of evidence in proof of this view. Case V., in which we have a lupoid eruption on the hand, combined with the so-called tubercular gumma, occurring four years after the amputation of the forearm for what was almost certainly tubercular disease of the wrist-joint, would rather suggest that all these lesions were due to auto-infection from a tubercular focus, such as caseous bronchial lymphomata, as Koenig[75] has shown to be the case in probably about 79 per cent. of all joint tuberculoses. Moreover, many tuberculoses of the skin, starting from tubercular lymphomata, or the

fistulæ communicating with a tubercular osteitis, are, as Koenig emphasizes,[76] anatomically not to be distinguished from lupus.

It seems to me far better to call all varieties tuberculoses, describing the special lesion according to its anatomical character or supposed mode of origin, as is done for the cutaneous syphilides, letting such terms as lupus and scrophuloderma drop from scientific nomenclature, as has already been so nearly done for such terms as rupia and ecthyma in the kindred disease.

Before leaving the subject it may be necessary to say a few words as to the evidence which leads me to place lupus so unreservedly among tubercular lesions. Friedländer had placed it, as before mentioned, on histological grounds, among the tuberculoses, and was followed by Köster and Besnier, while Hardy, Pick, Baumgarten, Vidal, and others[77] took the opposite view. Demme[78] found bacilli in very moderate numbers in three cases of lupus. L. Dautrelepont[79] found them in seven cases. Pagenstecher and Pfeiffer[80] inoculated three rabbits in the anterior chamber of the eye with secretion from lupus of the conjunctiva. The first inoculation was apparently successful, but no microscopic examination of the diseased iris was made. In the second and third cases, however, this was done, and numerous bacilli were found. A fourth case had produced no result after four weeks. They failed to find bacilli in the lupus of the conjunctiva used for inoculation number three, and in numerous preparations from other lupus cases. Cornil and Leloir[81] in twenty-two inoculations produced tuberculosis seven times. Two of the remaining animals died too soon to be of any value. The authors were inclined to believe that some of the other cases might have succeeded if they had waited longer. In their histological examination of twelve cases of lupus they found regularly the usual tubercle structure, but out of ten sections from each case, stained by Ehrlich's method, they only found the bacillus once, and then a single bacillus. This was in a case of lupus of the ear, occurring in a phthisical person. They concluded that lupus may be an attenuated form of tuberculosis. Malassez[82] did not find the bacillus, and his inoculations failed also. Morison[83] found no bacilli in ten cases, and mentions that Dr. Symington had the same experience in at least fifteen more cases. I have only had opportunity myself to make two inoculations with uncomplicated lupus. The first, as already related, failed entirely, and it is still too early to judge of the second.

Finally, Koch[84] has demonstrated the bacilli in four cases of excised lupus. The bacilli were always in giant cells, and occurred so sparingly that in one case twenty-seven, and in another forty-three sections were examined before a bacillus was found. With these four, and three other cases from which only scrapings could be obtained, inoculations were made, and all gave positive results. In the face of so many successes by reliable observers I cannot admit that the question is still an open one, because there have been a certain number of failures. Dr. Morison,[85] who has been kind enough to give me the details of his examinations, states that the sections were kept in the staining-fluid three-quarters of an hour, in an oven at the temperature of the blood, and *completely* decolorized in nitric acid, 33⅓ per cent., which, as he states in his article, sometimes took as long as five minutes. Both these are doubtful proceedings, to the dangers of which Koch[86] has specially called attention as follows: "After a deeper staining, which gives decidedly better and more reliable results, nitric acid no longer completely decolorizes the stained layer, and sections which, as was specially mentioned, must be stained *for a longer time and very intensely*, retain always after the treatment with nitric acid, a moderately dark staining. The expression 'decolorized' is, therefore, here not to be understood literally. The failure in staining the bacilli seems in most cases to have depended on the fact that it was supposed the preparations must be altogether colorless after the nitric acid treatment, and that in order to attain this they have been *in part too little stained* and in part *allowed to remain too long in the acid.*"

The fact that Dr. Morison demonstrated the bacilli by this method, in other tubercular tissues proves nothing, for, as I have repeatedly found, where many are presented, a certain number will show when stained even by very inferior means. The extremely small numbers in which the bacilli occur in most cases of lupus would itself account for most of the failures.

(*To be continued.*)

A PAINLESS ESCHAROTIC.

BY N. A. RANDOLPH, M.D.,
AND
SAMUEL G. DIXON.

IN the rapidly growing literature of cocaine, it is not impossible that the application which we here

* Koch recommends the use of oil of cloves, which dissolves the aniline colors out of the preparations. Before I knew this, I noticed that almost all my preparations faded very rapidly.

† Pfeiffer reported later (Ber. klin. Woch., 28, 1883) the discovery of the bacilli in sections of lupus of conjunctiva.

briefly describe, has already been employed; but, if so, it has escaped our scrutiny of the later developments regarding this drug.

When a saturated solution of cocaine hydrochlorate in strong nitric acid is applied to the uninjured skin, the ultimate result is precisely that which would occur upon the similar application of pure nitric acid, but the time required for the formation of a deep eschar is considerably longer in the former than in the latter case.

We have experimented with the mixture just mentioned upon several individuals, ourselves included, and can safely say that the sensations attending its application cannot be accurately described as painful. There is, however, a slight pricking sensation soon after the mixture is first dropped upon the skin.

Upon one person a control-experiment was instituted in the following manner: Upon his right arm were placed four drops of strong nitric acid, while upon the same point on his left arm was similarly disposed the same quantity of the mixture of nitric acid and cocaine hydrochlorate. The pure acid caused great pain, and was speedily removed; the mixture, which was applied later, caused a sensation described as "tickling, with slight pricking," which soon passed away.

In two cases the burned points were covered with absorbent cotton wet with a two per cent. solution of cocaine salicylate — a salt which we have not yet seen described, but which, in addition to the peculiar properties of its contained alkaloid, appears to be somewhat antiseptic. There has been no discomfort after the formation of the eschar. Prof. Harrison Allen, to whom we presented a portion of our solution of the salt last mentioned, kindly reports that he has applied it several times in his practice as a substitute for other salts of cocaine, with good results.

BIOLOGICAL LABORATORY OF THE UNIV. OF PENN.,
January 16, 1885.

MEDICAL PROGRESS.

THE MICROBES OF INFANTILE DIARRHŒA.—At a late meeting of the Biological Society of Paris, M. CLADO presented the results of the joint researches of himself and M. DAMASCHINO upon the microbes of infantile diarrhœa. The observations were made upon some children while yet at the breast, who were affected with diarrhœa, and upon others convalescent from measles. In these conditions, the fecal discharges are green, and the diarrhœa is serious; or they may at first be dark, and become green on exposure to the air. This latter form, though less grave, frequently is a prelude to the diarrhœa of cholera infantum. The investigations were begun in 1883, before the last appearance of cholera, and have been continued ever since; and microörganisms, distinct from those existing in the discharges of cholera, have been plainly shown to exist in infantile diarrhœa.

The microbes are stained with methyl-blue for microscopic examination, and are present in vast numbers. They are rod-shape (*bacilles en bâtonnets*), of characteristic size and appearance, and exist almost exclusively in grave cases, and are more numerous as the disease is severe. They are much larger than the bacilli of tuberculosis, and their study is also easier, especially with an immersion objective. Most frequently they are in grape-like collections, in shape sometimes slightly curved, crescent-like, and exceptionally semicircular. Their extremities are not pointed, as are certain microbes found in diarrhœal discharges, but are rounded. The bacilli are never found in the interior of epithelial cells, or of epithelial masses, but always in their interstices. At times groups of the bacilli seem to be united by an albuminous material. When observed while fresh in a drop of distilled water, they at times are in motion, and seem to have for the centre of motion the middle portion of the microbe. In all cases, as convalescence progressed, the microbes proportionately became less numerous. These investigators hold that in all cases the results obtained have been constant, and they are at present making cultures as a further confirmation of their research.—*Le Progrès Médicale*, Dec. 27, 1884.

THE SIGNIFICANCE OF PYARTHROSIS IN SCARLATINA.—LÖFFLER has made the interesting discovery that there exists in the membrane of scarlatinous diphtheria a chain-shaped coccus. If one of these be introduced into a joint, inflammation soon results, and if simply introduced beneath the skin, an inflammation resembling erysipelas follows. He therefore concludes that probably the pyarthrosis accompanying this exanthem is due to the same cause. A case is cited in which a scarlatinous diphtheria, pursuing at first its ordinary course, became at length complicated with enlargement of the spleen and pericarditis with lung complications. On the tenth day fluctuation in the articulations of the second and third fingers of the left hand appeared. Three days subsequently, fluid was discovered in both knee-joints. A day later the boy died. Autopsy showed the presence of a purulent fluid in the joints already mentioned, and also in the ankle-joints. There was erosion of the articular cartilages, and in two of the fingers the epiphysis of the bones was destroyed by suppuration. Microscopic examination showed the presence of micrococci throughout the body and in the blood. They were very abundant in the affected joints, though in this situation the development had not proceeded so far as in the blood and on the skin, but the identity of the micrococcus in different parts of the body was undeniable. From consideration of all the facts, the conclusion is reached by Dr. Löffler that the infection primarily existing in the tonsils was, owing to an abrasion, carried secondarily by the blood throughout the body, thus causing the remarkable complication.—*Berlin. klin. Wochenschrift*, Nov. 3, 1884.

ULCERATIVE ENDOCARDITIS.—M. GRANCHER reported a case of ulcerative endocarditis to the Société de Thérapeutique which seems plainly to show the zymotic origin of the disease.

A man was long affected with heart disease, which finally showed the symptoms of ulcerative endocarditis without complications. The patient entered the hospital in a state of collapse. The case was diagnosticated as above, and experiments were at once begun to confirm the diagnosis. A drop of blood from the patient was taken each day. Every precaution necessary to accurate results was observed, and in all the flasks used for the culture there appeared in twenty-four hours at the bot-

tom of the vessel small granular masses made up of a conglomeration of very small micrococci. These were the same in every vessel. The patient finally died, and blood taken from the heart cavity gave by cultivation the same micrococcus. The aortic valves presented the common lesions of vegetative endocarditis, and microscopic examination of the surface of the valves showed the presence of the same organism.

Grancher intended to cultivate the micrococcus and to make inoculations to verify this observation, but unfortunately, when he resumed his investigations, he found the micrococci dead, and, some time having elapsed, all efforts at further cultivation failed, and experimentation was impossible. There seems to be no doubt, however, of the zymotic origin of the disease.—*Journal de Médecine de Paris*, Dec. 20, 1884.

Is the Removal of the Thyroid Body Warranted from a Physiological Standpoint?—The experiments of Zesas (which appear in *Archiv für klin. Chirurgie*, Bd. lxxv. Heft 2) upon the effect of the removal of the spleen and thyroid body, have given interesting disclosures concerning the function of these organs. During the experiments, extirpation of the spleen was alone well tolerated, but removal of the thyroid body was followed by striking manifestations. The animals for two weeks refused nearly all food, were drowsy, walked with tottering gait, and died usually in convulsions. These effects were also manifested in animals which had survived the removal of the spleen, and from which subsequently the thyroid body was removed. In them was also observed an enormous increase in the number of the white blood-corpuscles. In those animals from which the thyroid body alone was removed, the increase of the white blood-corpuscles was not so remarkable as it was in those in which the spleen only had been extirpated. Ablation of the thyroid body produced notable anæmia of the brain and hypertrophy of the spleen.

The lymphatic glands, especially those of the mesentery, were frequently greatly enlarged, and filled with a black pigment. It, therefore, appears from these experiments that the thyroid body not only has the function of acting vicariously for the spleen, but also plays an important part in regulating the supply of blood to the brain, and may, in fact, be considered as a special organ for this purpose. Zesas decides from his experiments that the removal of the thyroid body is not justifiable, and his conclusions are strongly supported by the results of this operation performed by Kocher on man for the scrofulous degeneration of the organ.—*Centralblatt für Chirurgie*, December 20, 1884.

Paralysis Resulting from Hypodermic Injections of Ether.—In the *Revue Médicale* for December 20, 1884, M. Arnozan calls attention to paralysis resulting from hypodermic injections of sulphuric ether. In four cases the paralysis of the muscles, affected by the puncture, appeared shortly after the injection was made. The paralysis seemed peripheral in its nature, as was shown by the attending changes in electrical excitability (suppression or diminution of faradic excitability, increase of galvanic excitability, return of voluntary motion before the return of faradic excitability); improvement was remarkably accelerated by the continued current. The question is how the ether produces the paralysis, whether by rendering the muscular fibre incapable of contraction, or whether by its injection the terminal intramuscular nerve filaments are disorganized. Experiments conducted by MM. Arnozan and Salvat, and practised upon a rabbit, show that the injection of ether produced on all occasions an almost instantaneous paralysis. After some days the rabbit was killed, and lesions of the nerve fibres were very distinct.

M. Arnozan concludes his observation by suggesting that in the hypodermic use of ether, care should be taken in all cases to avoid introducing it into the muscular tissue, simple subcutaneous injections being harmless.

Implication of the Sense of Hearing in Blenorrhagic Rheumatism.—Hermet, noting the rarity of this complication, discusses at length the condition as it existed in a case in which the clinical symptoms were carefully observed. The rheumatism affected various joints throughout the body, and it was noticed that amelioration of the general symptoms was alternated by loss of hearing, and, *vice versâ*, improvement in the auditory function was followed by return of the rheumatism elsewhere. The pain in the ears, during the attacks of deafness, was intense, all sounds, especially those of a high pitch, causing extreme pain. Examination of the ears revealed (in the left) a calcareous plate situated at the posterior border of the tympanic membrane, and which was probably due to the result of a former purulent otitis, which had followed a previous attack of rheumatism. The right ear was normal. Reviewing the anatomical relations of the ossicles and the tympanic membrane, Hermet logically concluded that the impairment of hearing is due to the extension of the rheumatic arthritis to the articulations of the ossicles. Accordingly, when the tympanic membrane, vibrating under the impulse of the sonorous waves, communicated motion to the chain of bones, pain was experienced, inasmuch as the attachment of the handle of the malleus to the membrana tympani necessitates motion in every articulation of the chain. The fact that during silence there was entire absence of pain, strongly confirmed the conclusions reached, and the observed alternation of the auditory and general manifestation of the disease left but little doubt of the correctness of the diagnosis—blenorrhagic rheumatism of the tympanic bones.—*L'Union Médicale*, December 25, 1884.

Plastic Operations upon the Palate.—M. Ulysse Trélat, in a paper on plastic operations upon the palate and the determination of the age at which it is proper to operate, reaches the following conclusions:

1. It is not necessary to perform plastic operations in this locality before the child has reached its seventh year.

2. Children who are to be operated upon should be carefully drilled in articulation of vocal sounds from the time they first begin to speak up to the time of operation, and the drill should be resumed at once after the operation. Functional cure is hastened and the ability to enunciate distinctly is rendered more certain by such a course.

Should harelip exist, along with cleft palate, the indications for operation are no longer the same. In such

cases, it is advisable to operate in the first month or within six months after birth. The measure of success, as relates to ability to articulate distinctly, here again depends upon careful training before and after the operation.

M. Trélat further remarks, concerning the operation, that when the division extends from the alveolar borders to the veil of the palate and palatine arch, success is possible, but failure often results. Plastic operation is unnecessary when the fissure is not of sufficient width to admit fragments of considerable size; simply bringing and retaining the parts in apposition is preferable.

Plastic operations are not dangerous. In forty-six cases operated upon by M. Trélat, all recovered. He operates with the patient in a horizontal position, the head bent far backward, so as to prevent as fully as possible access of blood to the bronchi. The food should be semi-liquid for ten or twelve days succeeding the operation. Cure ordinarily is effected in from four to eight days.—*Gazette Hebdomadaire*, Dec. 26, 1884.

The Radical Cure of Hernia.—At a recent meeting of the Surgical Society of Paris, M. Bouilly presented a patient upon whom he had operated for the radical cure of double scrotal hernia, with complete success. The patient was a man, 50 years of age, and the hernia so large that it reached to the middle of the thigh. Replacement of the bowel, so as to permit the wearing of a bandage, was the end to be attained, and with this result in view M. Bouilly operated. The sac was opened and the intestine easily replaced, and its descent prevented by closing the opening through which it had protruded. This was done by forming a pouch by suture of the sac at the neck, suture of the ring being impossible. The remainder of the sac, contained in the scrotum below the neck where the suture was made, was removed. The same operation was then performed on the other side. The wound was treated antiseptically and drainage-tubes introduced. Two days subsequently, inflammation was found to exist. This was the result of imperfect drainage, one of the tubes having been removed for the purpose of cleansing it, was improperly returned, and the pus was unable to escape. Fortunately, however, the inflammation did not extend to the peritoneum, and the patient recovered, and the application of a bandage prevented the protrusion of the hernia.—*Revue Médicale*, December 27, 1884.

Treatment of Blenorrhagia.—M. Edmond Delorine, in an exhaustive paper on the nature and treatment of blenorrhagia in man, arrives at the following conclusions, relative to the management of the affection:

Recent researches upon the nature of blenorrhagia have completely modified existing methods of treatment. Injections, employed from the first appearance of the disease, or from a time closely related to its first appearance, are at present used much more unreservedly than heretofore, and without any adjuvant, except hygienic measures. It is impossible, owing to dearth of exact information, to pronounce definitely upon the value of topical applications now so highly lauded, and a definite conclusion upon this point can only be reached after further investigation. Finally, preventative injections, after impure coitus, or in patients who manifest the first symptoms of the disease, deserve to be resumed. —*Archives de Medicine et de Pharmacie Militaires*, Jan. 1885.

Calomel in the Treatment of Otorrhœa.—Dr. J. Gottstein, in the *Archives of Otology*, Sept. to Dec. 1884, strongly recommends the use of calomel in the treatment of otorrhœa. He says: During the past year I have used the calomel by way of trial in a number of cases that have seemed suitable, especially such as could be submitted to daily observation.

I have satisfied myself (1) that the remedy is absolutely free from irritation to the mucous membrane of the middle ear; (2) that it forms neither upon nor in the mucous membrane any precipitate difficult of removal; (3) that surprising results are often obtained under its use.

Accordingly, since the beginning of the present year, I have, in my private practice as well as in my polyclinic, employed calomel in the treatment of all cases of otorrhœa in which, following Bezold's direction, I had previously made use of boric acid alone, or as a supplementary means. I withheld the calomel only from such patients as, coming from a distance, I had an opportunity to see but once.

My observations now exceed eighty in number, so that I feel justified in communicating the results of my experience with this method.

My method of procedure is as follows: The ear is, in the usual way, syringed carefully with a weak sublimate solution (one-tenth per cent.); the residue of the secretion is forced into the external meatus by the employment of Politzer's method, and then removed by syringing; and, finally, the ear is well dried with cotton.

The calomel (vapore parat.) is then blown in through a powder-blower,[1] and the auditory canal closed as well as possible by means of cotton. The further treatment is the same as with the boric acid.

That on which I lay the most stress is that calomel, in my opinion, has a much more certain and decided antiseptic action than the boric acid.

I am anxious to avoid the error into which those authors fall who overestimate the value of the remedies recommended by them. Calomel also fails in some of the cases in which powerful antiseptic action is desired, because considerable tissue alterations in the drum-cavity are absent. Yet I have, with no method of treatment, not even with the boric acid, attained such speedy results as with this remedy in acute as well as in chronic forms of otorrhœa.

The calomel is also suitable, as is the boric acid, for employment after operations in the middle ear, cauterization with nitrate of silver, the use of the galvano-cautery, and in conjunction with the alcohol treatment. In these cases, the powerful antiseptic action of the remedy is conspicuous.

[1] In my consultation hours, I make use of the powder-blower of Kabierski (*Centralblatt für Chirurgie*, 1883, No. 33), which I have found, after long trial, the most suitable for the treatment of the ear as well as of the nose and larynx. It has the advantage that it does not need to be filled for each case, that the insufflation can be made with ease and accuracy during the examination of the parts, and, finally, a separate tip can be used for each patient, a measure necessary for the attainment of a thorough antisepsis.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JANUARY 24, 1885.

NEPHRECTOMY IN INFANTS AND CHILDREN.

AT a recent meeting of the Clinical Society of London, the proceedings of which are recorded in the *British Medical Journal* for November 1, 1884, MR. GODLEE read a paper on a case of abdominal nephrectomy for sarcoma in a boy twenty-two months of age. The removal was accomplished without any difficulty; the cure was uninterrupted by a single bad symptom; and the child was discharged in six days. In six months, however, recurrence took place in the right iliac fossa; the tumor rapidly increased in size, passing down into the scrotum; and death ensued soon after.

Mr. Godlee, in his comments on the case, mentioned eight other examples of extirpation of the kidney for morbid growths in subjects of tender years. Including his own, the 9 cases show that 5 died of the immediate results of the operation, 3 recovered, but died subsequently of a recurrence, while 1 was well when last heard of. Despite these unfavorable results, and in view of the hopeless condition of these patients if left alone, he argued that attempts should be made to remove neoplasms at an early stage; but, at the same time, plead against interference when the growths had attained a large volume.

Unless we greatly mistake, the weight of opinion is against nephrectomy for tumors in children, and we believe that the majority of surgeons will endorse, so far, at any rate, as sarcoma in early life is concerned, the view expressed by Mr. Henry Morris, in the fifth volume of the *International Encyclopædia of Surgery*, which has just been issued from the press. He says: "It is probable that future experience will exclude from the category of cases for which nephrectomy, by any method, should be done, tubercular disease, and renal sarcoma in children, as well as cancer at any period of life."

We have before us the notes of 11 extirpations of the kidney for neoplasms in children, 10 being for sarcoma and 1 for adenoma, an analysis of which shows that the operation has thus far been of the most disappointing nature. It may be mentioned that the surgeons were Hueter, Jessop, Kocher, Czerny, Hicquet, Rawdon, Réczey, Little, Ollier, Sir Spencer Wells, and Godlee. Of the entire number, 8 perished from the immediate results of the operation, thereby showing a mortality of 72.72 per cent., and 3 recovered, namely, the cases of Jessop, Hicquet, and Godlee. Ten of the operations were by the ventral incision, of which 8 died; and 1 was by the lumbar incision, which recovered. Of the 3 recoveries, the patient of Hicquet remained well at the expiration of three months, the date of the last report; while the disease recurred, respectively, in six and nine months in the cases of Jessop and Godlee.

It will thus be seen that the immediate mortality was 72.72 per cent., and that the disease returned in 66.66 per cent. of the recoveries. In addition to this gloomy record, we have, however, to state that the operation does not prolong life, since the average duration of life was fifty days, as against an average life of between seven and eight months in the same class of subjects, when the disease is allowed to pursue its natural course.

While we are of the opinion that nephrectomy is unjustifiable in children the subjects of renal neoplasms, further experience may show that Mr. Godlee is right in asserting that interference is proper in the early stage of the affection, particularly as Kühn states that secondary growths are found in only 28 per cent. of sarcomata of persons of tender years. But when we consider that these cases rarely come under the observation of the surgeon until the tumor has attained a considerable volume, it can scarcely be expected that the future will show better results than those now recorded.

Although the extirpation of the kidney for sarcomata is an extremely lethal procedure in children, it is gratifying to know that the operation may be resorted to with an excellent prospect of a successful issue in the same class of subjects suffering from other renal lesions. Thus, of 2 ventral nephrectomies for hydronephrosis, at the age respectively of four and seven years, in the hands of Thiersch and Thornton, both recovered; while 2 additional cases for suppurative lesions, done at five and seven years by Baker and Bardenheuer, both by the posterior incision, were cured. Rawdon, however, had a death from suppuration of the opposite kidney after lumbar nephrectomy for rupture of the organ.

The greater success in these five cases was doubtless due to the comparatively short time required to perform the operation, and to the consequent less shock experienced by the patients. In addition to this element of success, the subjects were older, their average age having been seven years, as against four years for those suffering from tumors. Other points in their favor were the slight risk of hemorrhage, and the diminished danger of peritonitis, three of the kidneys having been removed through the loin. In the cases of tumor, on the other hand, the eight deaths followed the ventral method of operating, the fatal issue having been due to septic peritonitis in three, to collapse in four, and hemorrhage in one.

THE OBSTINATE VOMITING OF PREGNANCY.

The vomiting of pregnancy, although a common affection, has proved as unsatisfactory in theories as in therapeutics. It was formerly called sympathetic, and is now generally known as reflex—we have changed the name, but we have not thus added to our knowledge.

A somewhat curious fact which has been reported at different times, and to which our attention has recently been recalled by a Delaware physician who gives an instance under his own observation, is that the husband as well as the wife may suffer from the so-called morning sickness. This sickness simply results from a mental impression; seeing a person suffering greatly from nausea and vomiting, especially when one has a deep interest in the sufferer, may induce a similar condition in the witness. When one crosses the Channel in a crowded steamer, the passage being rough, and sees the numberless basins provided for the sick, and observes them in such constant use, even though he is ordinarily a good sailor, he may be compelled to confess to some nausea, even if he does not actually vomit.

While the nausea and vomiting of pregnancy prove in the great majority of cases an indisposition rather than a disease, disappearing about the fourth month —in others, obstinate vomiting may result in death. Cases of fatal vomiting in pregnancy are by no means numerous. Guéniot, in 1863, gave only 118, and Kleinwächter more recently refers to the rareness in German literature of simple cases of obstinate vomiting. Nevertheless, the distressing character of the vomiting and the possibility of a fatal result being present in each case, lead us to turn with interest to a paper recently read by Dr. Graily Hewitt before the London Obstetrical Society upon the subject, and the discussion which followed, which may be found in the current London weeklies.

Dr. Hewitt, who is nothing if he be not the chief representative of the mechanical pathology of uterine diseases, brings physical views to explain the obstinate, uncontrollable, or incoercible vomiting of pregnancy. His explanation of the disease is that it results from interference with the normal expansion and growth of the gravid uterus. This interference may arise from incarceration in the bony pelvis of the uterus with version or flexion, or from rigidity and undue hardness of the os and cervix; the former he considers the more important factor.

Of the nine gentlemen participating in the discussion, not one sustained Dr. Hewitt's views in full, and, indeed, only one or two gave them even a partial support. Two of the gentlemen, Drs. Hicks and Bantock, stated that they had never seen uncontrollable vomiting, while, on the other hand, Dr. Matthews Duncan, whose line of thought rarely coincides with that of other men, or who at least sometimes deals in verbal contradictions, stated that "he knew no controllable vomiting of pregnancy." This statement seems to illustrate what Lord Bacon called "an unsteady use of words," confusing the reader.

Dr. Barnes held that the vomiting of pregnancy is "a safety valve for nervous energy, and a safeguard against nervous seizures, such as eclampsia," while Dr. Playfair stated that "it was a neurosis of an intense degree." Neither theory is satisfactory, for a woman prostrated almost unto death by vomiting has no superfluous nervous energy and yet she continues to vomit, and the assertion that the disorder is a neurosis is unproved. Moreover, naming a thing a neurosis does not tell us what it is.

When theories so utterly fail of establishment, and give no clear directions in therapeutics, the majority of practitioners will probably go on in the old way, first treating each case according to its conditions, and then, no obvious local disorder being present, mainly in an empirical way.

Doubtless some patients vomit because the uterus is displaced, and the physician will correct the displacement, if he can. But such cases by no means constitute the majority. In still rarer cases, the disorder may result from rigidity of the cervix, and then the Copeman method of digital dilatation may prove useful; yet we believe that if all the cases in which this method has failed were published, they would far outnumber those in which it has succeeded. Bennet's method of applying nitrate of silver to the cervix, revived by Dr. Sims and by Dr. Jones, may be required in some cases. But when all the patients amenable to these methods of treatment are numbered, the great majority remain for whom we have nothing to offer but empiricism, and we will use one or several of those remedies—such as tincture of nux vomica, small doses of ipecacuanha, or of arsenic, belladonna, morphia, ether spray to the epigastrium, oxygen, etc., possibly even pop-corn or inogluvin—which have proved or been believed useful in other cases of the disorder.

INTERCHANGE OF NERVE FUNCTIONS.

THE subject of the reunion of severed nerves has always been an interesting study to the physiologist, and a very important one to the practising physician. That cut nerve trunks can reunite if possessed of the same function—that is, motor nerves to motor nerves and sensory nerves to sensory nerves—is not now doubted. But all attempts to unite the cut end of a purely sensory nerve to the cut end of a purely motor nerve have failed. Quite recently, however, DR. EDWARD T. REICHERT has repeated these experiments in a modified form, in the laboratory of Prof. Schiff, at Geneva, and his results are published in the *American Journal of the Medical Sciences* for January. His object was to determine whether fibres of nerves of entirely different origin and function, though still motor or sensory, would unite, and should regeneration occur, to ascertain whether a motor nerve was capable of conveying impulses peculiar to another motor nerve, and a sensory nerve impulses peculiar to another sensory nerve. To this end, the vagus and hypoglossal nerves were selected as being of distinct origin and function and as affording the best facilities for observation. Five dogs were prepared by Prof. Schiff by cutting the hypoglossal on one side close to its exit from the cranium, and the vagus at the thyroid gland. The *peripheral* end of the *hypoglossal* was sutured to the *central* end of the *vagus* by a silk thread through the neurilemma.

We have not space to detail the experiments, but the result proved that the motor fibres of the vagus in the five dogs operated upon, united to similar fibres of the hypoglossal, and that the hypoglossal fibres conveyed impulses which were peculiar to the vagus apparatus. They showed, moreover, that in at least one dog, irritation of the sensory fibres in the hypoglossal trunk gave rise to impulses which were conveyed by the sensory fibres of the vagus to the vagus centres, and produced effects like those induced by excitation of the vagus trunk, thus proving in both instances that a motor or sensory nerve can convey impulses peculiar to another motor or sensory nerve of entirely different origin and function. They indicated likewise that, at least in some nerves, the effects produced by impulses from the periphery are not dependent upon any peculiarity of the impulse due to physiological peculiarities of the peripheral sense-organs or nerves, but upon the peculiar physiological properties of the nerve centres. Hence we have respiratory movements, etc., occurring in the tongue, brought about by impulses from the vagus centres through the hypoglossal nerve, and effects on the respiration, pulse, pressure, and vomiting centre through impressions carried to the vagus centres by impulses generated in the hypoglossal.

At least three physiologically distinct sets of motor fibres were united with fibres of the hypoglossal, namely, fibres conveying inspiratory impulses, fibres conveying expiratory impulses, and fibres conveying œsophageal impulses, the first two doubtless consisting of fibres going through the recurrent laryngeal to the muscles of the larynx, and the latter set forming part at least of the fibres belonging to the same branch.

These are very important results, and they prove that the functions, at least of nerves of general sense and motion, are based upon the nerve centres rather than upon peripheral distribution. It will be noted, however, that they do not show that severed motor nerves can be united to severed sensory nerves, but that sensory nerves of one trunk will unite with those of another trunk in a mixed nerve conducting an entirely different sort of sensory impressions from those conducted by the nerve with which the union took place. The same is true of motor nerves.

The experiments also showed that a sensory nerve can be made to conduct impressions in a direction opposite to that in which it originally conducted. Thus the sensory fibres in the trunk of the hypoglossal, at the point of union with the vagus, are recurrent fibres (sensory fibres coming from the superior cervical nerves, through the descending branch of the hypoglossal, and from that branch toward the centre), and, therefore, normally conduct impressions not directly toward the centres, as is usual with sensory nerves, but first peripherally, making a circuit, as it were, before reaching the centres. Since, therefore, the sensory fibres of the hypoglossal, uniting with the sensory fibres in the vagus conducted impressions to the vagus fibres, it is evident that these impressions were conducted in a direction contrary to that of the normal. Thus, too, were confirmed the results of the famous experiment of Paul Bert, who laid bare the back of a rat and a part of the end of the tail, and caused the latter to grow to the former. After union was established, the tail was cut from the body at the root. He now found that when he irritated the end of the tail, formerly the root, the animal gave signs of pain, thus showing that the impression was conveyed in a direction opposite to that of the normal route; or, in other words, that the nerve which formerly conveyed impulses from the end of the tail toward the root, now conveyed impressions in an opposite direction.

GASTROENTEROSTOMY.

IN the *Correspondenzenblatt für Schweizer Aerzte*, for November 1, 1884, may be found the report of what must be regarded as the most remarkable case of gastric surgery that has as yet been recorded. On the 15th of July, 1883, PROF. SOCIN resected the carcinomatous pylorus of a woman, forty-three years of age, who subsequently enjoyed excellent health for upwards of eight months. At the expiration of this time, she began to be troubled with symptoms

of dyspepsia; and on the 23d of May, 1884, a recurrent tumor, adherent to the abdominal wall, the pancreas, and the liver, was discovered. On the 5th of June, gastroenterostomy was practised; the patient made a rapid recovery, and at the end of four months her digestion was excellent, she had slightly gained in weight, and the tumor had only increased in volume.

The establishment of an opening between the jejunum and the stomach, to insure the passage of food into the intestinal canal, and thereby prevent death from starvation in cases in which pylorectomy is contraindicated, has been resorted to at least twelve times for carcinoma of the pylorus, the operators having been Wölfler and Lauenstein, each in two cases, and Billroth, Rydygier, Kocher, Monastyrski, Lücke, Courvoisier, Ransohoff, and Socin, each in one case. Of the twelve, nine, or seventy-five per cent., died; and three, or twenty-five per cent., recovered. Of the recoveries, two were living at the end of four months, and one at the expiration of six months. Rydygier, in March, 1884, had a success in a case of ulcer of the duodenum.

These results indicate that gastroenterostomy is as deadly an operation for carcinoma as is pylorectomy. It has, however, succeeded in prolonging life in one case out of every four, so that the patient may be given the chance if it be desired.

Among the more recent attempts to establish a communication between the stomach and the intestine, is the novel case of Dr. Conner, of Cincinnati, which is recorded in The Medical News for Nov. 22, 1884. The entire stomach was extirpated "with the hope of attaching the cardiac end to some portion of the intestinal tract, so that the fluids poured out in the upper part of the small intestine might flow down to meet the food, and cause digestion in the part of the intestine where they come together." As the patient died upon the table, the operation was not completed. However feasible it may be, so far as surgical procedures are concerned, we fail to see that, in the event of recovery, it could be of any service, from the fact of the supply of the gastric juice being entirely cut off. Hence, we trust that the operation will not find imitators.

ORIGIN OF BLOOD GLOBULES.

The origin of blood corpuscles is as fruitful a source of speculation and observation as are the theories of life itself, and is likely to continue so until more positive and direct demonstration is brought to bear upon the processes which underlie it. In our issue for December 6th, we called attention to some observations by Prof. Rindfleisch, based upon a report of two cases in which hæmatoblasts or nucleated red corpuscles were found in the lymphatic glands, which tended to show that the formation of red blood disks is sometimes partly transferred to these glands. Since then we have been informed of other instances of red or raspberry-colored lymphatic glands, and our attention has been called to a paper by Dr. A. W. Johnstone, entitled "Experimental and Microscopical Studies on the Origin of the Blood Globules," published in the *Archives of Medicine* for August, 1881, in which he states that red blood disks are to be found in most sections of lymphatic glands, although they are very scanty, and he infers that the formation of a few red blood disks is a normal function of all lymphatic tissues. In a later note to us, Dr. Johnstone suggests that an increased or compensatory function of this kind is assumed by the lymphatic glands in animals which survive the operation of splenectomy, while in other cases it may so far increase, at times, as to become pathological, as in Prof. Rindfleisch's cases.

We have only one suggestion to make with regard to the presence of red blood corpuscles in the normal lymphatic glands. It must be remembered that these glands are vascular, and that in the sections made of them in the fresh state for microscopic study, the little bloodvessels must be cut across, and the blood corpuscles thus escape. Can it be that the red disks which thus escape are sufficient to account for those found in Dr. Johnstone's sections?

REVIEWS.

A Manual of Diseases of the Throat and Nose. By Morell Mackenzie, M.D., London. Vol. II. Diseases of the Œsophagus, Nose, and Naso-Pharynx. 8vo. pp. 550, Philadelphia: P. Blakiston, Son & Co., 1884.

The Same. Pp. 400. New York: William Wood & Co., 1884.

The present volume—the second—completes a literary labor undertaken by the author some twelve years since, and has followed the first volume after an interval of four years.

In a notice necessarily as brief as the present one we can do little more than congratulate the writer and attest our appreciation of the energy that has dictated midst manifold professional duties the undertaking of such an extensive literary task and of the skill, fidelity, and thoroughness with which it has been accomplished.

The first volume of Dr. Mackenzie's manual was quickly endorsed by the profession upon its intrinsic merits and became widely recognized and accepted as a standard work—not alone on account of the enviable reputation of its author, but likewise for its practical value as a text-book and its utility as a work of reference in the special subjects of which it treated.

The present second volume, modelled on the same general plan as its predecessor, and dealing with the

diseases, etc., of the œsophagus, the nose, and the naso-pharynx, fully sustains both the author's reputation and that of his work. Again, we have presented in compact and readable form the collated results of extensive bibliographical research, the thorough and painstaking compilation of the recognized work of others—and in pointing out this fact we are not unmindful that judicious compilation is an art that is alike necessary and productive of the most useful results—and finally the well-considered expression of a careful, personal study of the subject at issue—all matters being treated in a broad and scientific spirit.

One element alone, we venture to remark, is often lacking, and its omission forces itself upon the attention of the careful reader. The impress of authorship, it is true, everywhere exists throughout the pages, but that of the author's individuality will often be vainly sought for.

Dr. Mackenzie's exceptional experience in observing the diseases with which he deals fully equips him to assume and fufil the *rôle* of teacher, to him and to his published work, the profession, as a matter of right, look for guidance in the matter of this special class of affections.

With undue modesty, however, he too frequently prefers to recount the experiences of others in preference to his own, and the desire of the reader to learn the latter is hence doomed to disappointment.

No more striking commentary on the very rapid advances that are being made in all the departments of the specialty could be found than exists in the very pages before us. Although but a short time has elapsed since the work has left the author's hands, important additions have already been made to our store of knowledge; these are, as a matter of course, not included in the present edition. Notably is this the case in the matter of the pathology and pathological anatomy of the affection termed "hay fever," which is treated of at some length, according to the older views, by the author.

The latter alludes to the never-ceasing work imposed by such frequent modification of views and the constant additions to literature; but after all, in reality, the omissions to which we allude serve only by their infrequency to add additional emphasis to the opinion above expressed as to the general completeness of the work.

As originally planned, and as advertised, Dr. Mackenzie's work was to have inc[illegible] section on diseases of the neck. This he has been obliged to omit, the sections on diseases of the nose and naso-pharynx having grown under his hands to such dimensions that it has been found impossible to include it and retain the book within reasonable limits. It is promised, however, as to appear shortly in a separate form, as one of the series of "Essays on Throat Diseases," with which the author's name has been long and favorably identified.

It is unnecessary, perhaps, to add that we entertain a high opinion of Dr. Mackenzie's treatise; the more that it is carefully studied, the more valuable will it appear, and the more apparent will become the obligation of both general practitioner and specialist to its distinguished author.

ELEMENTS OF SURGICAL DIAGNOSIS. By A. PEARCE GOULD, Assistant Surgeon to the Middlesex Hospital, London. 12mo. pp. 584. Philadelphia: Henry C. Lea's Son & Co., 1884.

ALTHOUGH issued as a student's manual, this book will be found to be a most useful guide for the hard-worked practitioner. Some parts bear evidence of hasty composition, and a few points are omitted which should have been inserted, but these faults will doubtless be remedied in a future edition, and are more than compensated for by the general excellence of the work in its entirety. Mr. Gould's style is eminently clear and precise, and we can cordially recommend the manual as being the outcome of the efforts of an honest and thoroughly practical surgeon.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, January 15, 1885.

THE PRESIDENT, FORDYCE BARKER, M.D., LL.D., IN THE CHAIR.

THE ANNUAL ELECTION OF OFFICERS

resulted as follows:

President.—Dr. A. Jacobi.

Vice-President.—Dr. C. C. Lee.

Corresponding Secretary.—Dr. L. Elsberg.

Member of the Board of Trustees.—Dr. A. L. Loomis.

Member of the Committee on Admissions.—Dr. A. S. Hunter.

Member of the Committee on Medical Education.—Dr. F. R. Sturgis.

Member of the Committee on Ethics.—Dr. A. H. Smith.

Member of the Committee on Library.—Dr. E. D. Hudson.

ANNUAL REPORTS OF OFFICERS.

The reports of the Council, the Treasurer, the Statistical Secretary, the Board of Trustees, and the Treasurer of the Board of Trustees were read. The report of the last named showed that during the past year $1880 were contributed toward the liquidation of the mortgage on the property of the Academy, thus lessening the annual expenses of the institution by one hundred dollars. A systematic effort is now being made by a special committee having the matter in charge to raise funds to pay off the entire indebtedness, amounting now to only $5000, and there [illegible]ood reason for supposing that this desirable result will ere long be accomplished.

The report of the Committee on Library, which was read by Dr. John C. Peters, showed that the library of the Academy now contains about 35,000 bound volumes and 9000 pamphlets. During the past year there have been added to it 1278 bound volumes, 1875 pamphlets, and 7814 medical journals.

DEMONSTRATION OF KOCH'S CHOLERA BACILLI.

DR. E. C. WENDT exhibited under the microscope a specimen of the cholera bacillus, which had been sent to him by Dr. Koch. The bacilli were shown under a power of 2000, and in another microscope of 1200 power specimens of bacteria from the mouth were placed on

exhibition. Even with this lower power the difference between those which resembled the cholera bacillus and the genuine cholera microbe were readily distinguishable.

EXHIBITION OF NEW INSTRUMENTS.

Dr. N. D. Schuyler exhibited an obstetric forceps devised by himself. Its characteristics were a well-marked pelvic curve, a rather short cephalic curve, and shanks which were shortened, closely approximated, and having a decided curve upward. Among the advantages claimed for this instrument are the facility of delivery when the *ostium vagina* was small and when the perineum was very much elevated, as was apt to be the case in primiparæ, and the ability to use it without the necessity of the patients being removed to the edge of the bed.

Dr. Schuyler also exhibited a vaginal speculum, which, he said, possesses the following desirable points: (1) It is easily introduced; (2) when *in situ*, it affords the largest possible field for observation; (3) it is self-retaining and it gives the patient no pain or discomfort; (4) with it the uterus can be fixed and held in a steady position. It is a combination of Sims's, Thomas's modification, and Nott's specula, and consists of a posterior blade, two lateral blades, and a depressor, which also performs the function of an anterior blade. The lateral blades and anterior depressor are worked by levers and held by screws; they move up and down on a standard placed in the handle of the instrument. The posterior blade (Sims) is quite narrow for the first three-fifths of its length, and then gradually widens until it terminates in a stem for the handle and two wings, to which are attached the other blades and depressor. The hard-rubber handle and the anterior depressor are so arranged as to be readily removed. Both instruments are made by Tiemann & Co.

Dr. F. A. Castle remarked in regard to vaginal specula that the instrument originally designed by the inventor was apt to be greatly modified by the manufacturers. Thus the original speculum of Dr. Nott, which was designed to be used exclusively in the Sims position, was very different in character from that which is now ordinarily sold in the shops under the name of Nott's speculum. The alterations seemed to have been made so that the instrument could be used with the patient on the back.

Dr. W. Gill Wylie read a paper on

DISEASES OF THE FALLOPIAN TUBES; THEIR RELATIONS TO UTERINE DISPLACEMENTS, AND THE USE OF PESSARIES.

The paper being of considerable length, he was obliged, he said, to omit a large portion of it in the reading. He remarked in the outset that while the German authorities had long devoted much attention to the pathology of affections of the Fallopian tubes but little advance had been made in their treatment, until Mr. Lawson Tait had made known his great success in the removal of diseased tubes. Batty and Hegar, as well as Sims, had also, however, contributed to our knowledge of the subject.

Since May, 1883, Dr. Wylie said he had operated in 14 cases; 9 of them being at Bellevue Hospital and 5 in private practice. Of the 14 patients, 12 recovered and 2 died. Both of the latter were hospital cases and both died of septicæmia on the fifth day. Eight of the cases were of pyosalpinx, two of hydrosalpinx, and four of catarrhal diseases of the tubes, with peritoneal adhesions. With five exceptions, the ovaries themselves were also diseased, and attached to the tubes by adhesions.

An increased knowledge of disease of the tubes, he thought, would do much toward clearing up the subject of local peritonitis, which was often erroneously attributed in this country to cellulitis. Retroflexion and lateral versions of the uterus, with adhesions, were also frequently due to salpingitis. When such was the case, it could readily be understood how much injury might result from the use of pessaries under these circumstances. With the light thus thrown on the subject, the mechanical theory of uterine displacements would, he believed, sink into insignificance, and the space which had heretofore been given to it in the text-books would henceforth be devoted to a consideration of the diseases of the Fallopian tubes, with their consequences and treatment.

As to the etiology of these affections, as a rule, they were due to the extension of some pathological process from the lining membrane of the uterus to that of the tubes. In virgins salpingitis was comparatively rare. Gonorrhœa he believed to be a frequent cause of such disease, and in stating his convictions on this point a number of years ago, Dr. Noeggerath had been well in advance of the scientific thought of the profession. Whether he had as yet succeeded in establishing the invariable presence of the gonococci he was not able to state. Among prostitutes the sterility that was so common he thought was accounted for by the frequent existence of salpingitis in this class of women. This sterility, it had been noticed, was apt to continue even after such women had abandoned their evil life and married. When gonorrhœal inflammation reached the endometrium, it was unsafe to resort to local treatment during the acute stage, on account of the danger of producing peritonitis, and the pathological process was exceedingly apt to spread to the Fallopian tubes. The latter often became greatly distended on account of there being a stricture at their proximal extremities.

Other causes of salpingitis were syphilis and septic poisoning after abortion and later at full term. It was now frequent after abortion, because subinvolution and endometritis were more liable to occur after it than after ordinary labor, from the fact that the same precautions were not taken after the former. It had been found that local peritonitis was much more common over the posterior surface of the broad ligaments than over the anterior, and this was undoubtedly due to the fact that the Fallopian tubes opened upon the posterior surface. His experience, Dr. Wylie said, had led him to attach much more importance to localized peritonitis than to cellulitis, and while phlegmons were sometimes met with in the pelvic cellular tissue, he no longer believed in the existence of the so-called chronic cellulitis. Hystero-epilepsy and similar conditions, he thought, were always associated with degeneration of the ovaries accompanied with a catarrhal condition of the Fallopian tubes.

In treating of the symptoms of salpingitis, he omitted a consideration of the subjective manifestations, as there

was nothing to distinguish them from those of other diseased conditions of the pelvic organs. Pain in the iliac region, he remarked in passing, however, was much more marked in pyosalpinx than in other affections of the tubes. As to the objective symptoms, they might not be understood by an inexperienced observer; but they were plain enough to the expert, if he took proper care. It was his own practice to subject his patients to a prolonged course of preparatory treatment, consisting principally of applications of glycerine and alum; and where this had been done, he believed that a positive diagnosis could almost always be made with ease.

For our knowledge of the pathology of salpingitis, he continued, we had to depend entirely on the German writers, who had given a full and accurate account of it. As had been before remarked, the affection was almost always due to an extension of an inflammatory process from the endometrium to the tubes. The manifestation of the diseased action, however, differed in accordance with the difference of the parts in size, shape, and the character of the mucous membrane of each. Moreover, as the tubes could not be reached by local treatment, salpingitis almost always caused a greater or less amount of peritonitis, and almost always became chronic. If it were supposed that the uterus was enlarged and bent backward, and that the tubes were involved in an inflammation extending from the endometrium, it could be seen how lymph pouring out from them into the peritoneum would be likely to produce attacks of peritonitis. As the process went on, the broad ligaments would become rolled up with the tubes, and the ovaries be firmly fixed in them. Under such circumstances the pain produced by pessaries, warned us against their use; but if this was persisted in, there was great danger of causing thereby a rupture of the inflamed tubes, which were usually swollen and filled with infectious matter. If one of the tubes only was affected, it was usually the left.

Having spoken at further length of the surgical pathology and the manner in which the displaced uterus became fixed as a consequence of the salpingitis, Dr. Wylie referred to the treatment in cases with adhesions, where operative interference was not permitted. Instead of attempting to keep the uterus in position by means of pessaries, he said he was satisfied if he could get the organ in a movable condition by restoring the surrounding pelvic tissues to a normal condition, as far as possible. He had succeeded in tapping three cases. One of them was cured by the procedure; but he believed that it was in reality a case of abscess forming in the site of an old hæmatocele. The others were benefited, but not cured, by the tapping; and the only cure for these cases he believed to be the complete removal of the ovary and tube on both sides.

The concluding part of the paper was devoted to the best methods of performing this operation. In opening the abdomen, he believed, it was important that a small incision should be made. It should not ordinarily be longer than three fingers' breadth; which would allow the free use of two fingers. If a larger opening were made, ventral hernia was liable to result, because the abdominal walls had not been previously distended, as was the case when there were large tumors present. It was also important after the removal of the ovaries and tubes to secure perfect apposition of the deep fascia lata. It was his practice to feed his patients solely upon pancreatized milk for a few days before operating upon them, as this had the effect of greatly diminishing the quantity of gas in the intestines and reducing them to such a flaccid condition that they were not likely to interfere with the operation. When the omentum was found to be in the way and held fast by adhesions, he advised that the operator should get two fingers underneath it in one of the fossæ; when the adhesions could easily be separated. No hemorrhage was likely to result from this procedure; but when there was any hemorrhage it came from the omentum, and any vessels could thus be readily ligated if this should be necessary. In order to get at the ovary with facility, it was advisable to elevate the uterus and unroll the convoluted broad ligament.

DR. EMIL NOEGGERATH said that he differed very little from Dr. Wylie in his opinions on this subject; but there were a few points upon which he should like to say a word. In regard to the name, "Tait's operation," it had been clearly shown at the late International Medical Congress at Copenhagen that this was a misnomer, since long before Tait had published his brilliant results (as early as September, 1879), Hegar had reported no less than forty-two cases. Tait's claim to have the operation named after him could, therefore, be based only on the large number of times and the success with which he had performed it; and, he thought, in speaking of this, as well as other operations, it was much better to omit mentioning any name at all, as it was almost always liable to raise the question of priority. Personally, he was of the opinion that most cases of salpingitis were caused by gonorrhœa. He had for a long time been engaged in special studies to demonstrate the presence of gonococci, but had not as yet succeeded. The gonococci was also a diplococcus, and four kinds had been observed in the vagina. The difficulty was that no gelatine had yet been found in which the gonococcus could be raised; since in every preparation that had been tried, they would not grow in the second, third, and fourth generation. After the disease had lasted for several week, the gonococci were found in such small quantity that they could be only raised in gelatine; and, as had just been stated, no gelatine suitable for this purpose had as yet been secured.

As to the relations between salpingitis and the inflammatory processes resulting therefrom, and dislocations of the uterus, he believed that lateral versions combined with anteversion were the distinctive form of displacement dependent on this disorder. Retroversion was met with in exceptional cases, in connection with pyosalpinx and hydrosalpinx; but in the great majority of cases of salpingitis, where the amount of exudation was not extreme, but the uterus was immovable, or only slightly movable, there would be found anteversion with slight lateral version. Retroversion with adhesions was rare in his experience.

In the diagnosis, two varieties were noticed: (1) ordinary salpingitis, with slight secretion, and (2) salpingitis in the later stages with pyo- or hydrosalpinx. It was not necessary to feel the tubes themselves in order to make a diagnosis, since perimetritis without salpingitis was extremely rare. The shape of the tumor, in cases in which this could be made out, was, however, of

great importance. It was, as a rule, divided into three sections, conical in outline and running in the direction of the lateral diameter of the pelvis. As to the treatment in the extreme cases, nothing could be done except to resort to operation; but the large majority of cases were not ready for so radical a procedure, and something else had to be done for them. There was one kind of treatment which was much more successful than any other of which he was aware, and that was a sojourn at Fransensbad, in Bohemia; and he had seen a number of cases which had been practically cured by this, which for years had resisted all sorts of treatment, both in Europe and America.

Dr. A. J. C. Skeene, of Brooklyn, agreed with Dr. Noeggerath that it was a rare thing to see salpingitis, unless it had been produced by gonorrhœa. On the other hand, he differed from Dr. Noeggerath in believing that perimetritis without the tubes being affected was not at all rare. In the matter of diagnosis, he thought it was very difficult to distinguish between an enlarged tube, especially in the condition of hydrosalpinx, and a cystic ovary in Douglas's cul-de-sac. There was one point that had been overlooked, and which he thought was of service in making a diagnosis, and that was aspiration. If ciliated epithelium was so common in pyosalpinx and hydrosalpinx as had been represented, it was only necessary to draw off more fluid and examine it. Out of 21 specimens which he had investigated, the epithelium was found in 18. This raised the question of treatment, and he believed that it was a fact that many cases had been operated on before other measures had been given a fair trial. This he believed to be due to a large extent to Tait's example and success; and he thought that operation should never be resorted to until more conservative means had been thoroughly tried. In pyo- and hydrosalpinx, aspiration might perhaps sometimes result in a cure; the tube not refilling after the fluid had been withdrawn. Aspiration, therefore, he thought might prove useful, both as a means of diagnosis and of treatment.

Dr. P. F. Mundé said that ever since the publication of Dr. Noeggerath's article on gonorrhœa, in 1872, and more particularly since Mr. Tait had announced his great success in operating in cases of disease of the Fallopian tubes, he had paid considerable attention to this subject, and especially in regard to the matter of diagnosis. He was, however, not as yet satisfied on this point, and he thought that Dr. Wylie had failed to throw additional light upon it in his paper this evening. In the cases in which it was most needed, it was at present impossible to arrive at a positive diagnosis. In well-marked instances of pyo- and hydrosalpinx, there was not this difficulty, and in such cases he had twice performed aspiration without the subsequent refilling of the tubal sac. The cases in which Dr. Wylie had operated seemed for the most part to be those of the kind in which there were diffuse thickening and infiltration in each broad ligament, with the occurrence of pain and a discharge of purulent matter at irregular intervals. In such cases, he did not see how it was possible to make a positive diagnosis without resorting to laparotomy; and until we could perform this operation with the same success as Tait in England, he thought it was advisable not to attempt it. Under any circumstances, he did not believe that gynecologists would perform laparotomy very often in this condition. In certain instances in which the diagnosis was obscure, but in which the patients were willing to run the risk, he had himself operated, with the result of one death; but it was now his conviction that we were only justified in performing laparotomy in those cases of salpingitis in which a sausage-shaped tumor was present and there was no room for doubt about the diagnosis.

As to displacements, in connection with salpingitis, he believed that retroversion was as common as anteversion, although he agreed with Dr. Noeggerath that in the majority of cases of retroversion the uterus was not bound down by adhesions. In the way of treatment, beyond the use of hot vaginal douches, etc., he did not think there was much to be done except laparotomy in appropriate cases. In a number of instances, however, he had seen considerable benefit derived from the use of the galvanic current, and he advised that it should be applied every other day or perhaps every day for from fifteen to thirty minutes with a battery of from twelve to sixteen cells. By this means the diffuse swelling could sometimes be reduced and the pain suffered by the patient diminished. Still, he did not believe that cases of hydrosalpinx could be cured by this means.

Dr. Wylie, in closing the discussion, remarked that in the reading he had been obliged to omit some of the more important points of his papers for lack of time, and particularly in regard to the preparatory treatment which was often necessary before a correct diagnosis could be arrived at. If Dr. Mundé would adopt this plan, he did not believe that he would have the difficulty in making out the diagnosis of which he had spoken. It was his practice to make applications of glycerine and alum on a thin pledget of cotton two or three times a week, for at least six weeks, and sometimes he kept them up for three months. Then, at the end of this course of preparatory treatment, he was in the habit of putting the patient under ether; when, the thickening of the tissues having been relieved by the glycerine and alum applications, there was usually no difficulty whatever in determining the exact size and shape of the Fallopian tubes. But even if one did not feel positive that the tubes were diseased, there could be little doubt that the ovaries were in an abnormal condition; and he had rarely ever met with disease of these organs without the tubes also being affected. In all the fourteen cases in which he had operated, there was hardly one in which there was not more or less perimetritis. He, therefore, did not feel in doubt in regard to the diagnosis in these cases; and in all the more recent ones in which he had performed laparotomy, he had been enabled to announce to his class the exact condition which would be found on opening the abdomen.

As to aspiration, he had himself employed this; but not in the way that Dr. Skeene had suggested. The simple drawing off of the fluid could not, he believed, cure the patient, because in these cases of salpingitis a pyogenic membrane was formed, which would continue to cause accumulations. Diagnosis by aspiration had been proposed by Dr. Ferguson; but he believed it was safe to follow Tait's admonition, not to tap tumors which are to be operated upon. The cases in

which he had resorted to aspiration were those in which drainage was required. In the matter of displacements of the uterus in connection with salpingitis, his experience went to show that in women who had not borne children anteversion and lateral version were usually met with; but that in those who had borne children, the salpingitis was nearly always associated with retroversion.

REPORT OF THE COMMITTEE ON MEDICAL EDUCATION ON A STATE BOARD OF EXAMINERS.

For the Committee on Medical Education, Dr. C. C. Lee reported in regard to a series of resolutions which had been reported to it at the last meeting, recommending that the Academy should urge the passage of a bill by the Legislature providing for the formation of a State Board of Examiners, with power to grant licenses to practise medicine; that in the opinion of the Committee, it was inexpedient that the Academy should adopt such action at the present time.

THE NEW YORK COUNTY MEDICAL ASSOCIATION.

Annual Meeting, January 19, 1885.

THE PRESIDENT, WILLIAM DETMOLD, M.D., IN THE CHAIR.

THE ANNUAL ELECTION OF OFFICERS

resulted as follows:

President.—Dr. Charles A. Leale.

Vice-President.—Dr. Edward G. Janeway.

Recording Secretary.—Dr. P. Brynberg Porter.

Corresponding and Statistical Secretary.—Dr. Charles S. Bull.

Treasurer.—Dr. Whitman V. White.

Member of the Executive Committee.—Dr. William T. White.

THE TREASURER'S REPORT

showed a balance of $511.79 in the treasury.

DISTRICT ASSOCIATIONS.

On motion of DR. J. W. S. GOULEY, the following resolutions were adopted:

Resolved, That the President of the New York County Medical Association appoint a committee of three, with power to increase its number, to take into consideration the propriety and expediency of organizing district associations in New York City, as branches of this Association.

Resolved, That in case this committee should decide to report in favor of the foundation of such district associations, they be authorized to prepare a plan of organization, to be presented to this Association for action at as early a date as practicable.

The Chair appointed on this committee Drs. Gouley and A. Flint, Jr., and empowered them to select the third member of the same. On motion of Dr. A. Flint, Jr., the Secretary was requested to preserve copies of all papers read before the Association, and the discussion thereon published in the medical journals.

ADDRESS OF THE RETIRING PRESIDENT.

DR. DETMOLD, on vacating the Chair, made a few valedictory remarks, in the course of which he spoke of the remarkable success that the Association had achieved in the first year of its existence, which, he said, would forever serve to mark one of the most brilliant events in the medical history of this country. In his own professional career of over fifty years, there was nothing upon which he now looked with so much pride as the fact that he had been selected as the first President of the New York County Medical Association. Finally, he referred to the permanent value of the discussions upon them, requesting, in conclusion, that there might always be a full attendance at the meetings for the encouragement of those who would read papers in the future. Having thanked the members for their courteous indulgence toward him and for their very cordial coöperation in the admirable work of the past year, he bespoke the same for his successor, and then proceeded to introduce

THE PRESIDENT ELECT, DR. LEALE,

who, on taking the Chair, read a brief address, in the course of which he made several suggestions which, he thought, would increase the efficiency of the Association. One of them was, that the transactions of the Society should be published in permanent form. Having referred to the remarkable clinical advantages now afforded in New York, he suggested that reports of special cases would always prove of interest, and expressed the hope that every member would endeavor to contribute his part toward the scientific proceedings, however humble that might be. The suggestion made in the resolutions offered by Dr. Gouley he thought was an excellent one, and he said that he did not doubt that, if practically carried out, it would do a great deal toward increasing the interest in the Association on the part of the profession in all parts of the city.

NEWS ITEMS.

THE MILWAUKEE SCHOOL FOR SURGERY AND ANATOMY.—In view of the fact that large numbers of students of medicine yearly pass through Milwaukee on their way to enter the metropolitan medical schools, and that the majority of them begin their collegiate courses without adequate knowledge of the primary branches of medicine and surgery, and that in the colleges the fundamental principles of the science of medicine are, almost without exception, too little taught, a number of the representative medical men of Milwaukee called a meeting at the residence of Dr. Senn, to discuss the situation. They decided to found in Milwaukee a school of anatomy and surgery, in which the primary branches only of these sciences should be taught.

An association has been organized and duly incorporated under the laws of the State, with the following officers: *President*, Dr. N. Senn; *Secretary*, Dr. Horace M. Brown; *Treasurer*, Dr. Wm. Mackie; *Directors*, Drs. N. Senn, H. M. Brown, Wm. Fox, James Dorland, A. B. Farnham.

Rooms have been secured for the school, and a course of lectures and demonstrations will be commenced about March 1, 1885, to continue for three months from that date.

No diplomas to be considered as licenses to practise medicine will be issued, and it is the object of the school only to furnish to students of medicine the best possible

facilities for acquiring a thorough knowledge of the primary branches of medicine and surgery.

The following gentlemen have been chosen by the Board of Directors to fill the various chairs:

Lecturer on Surgery, Dr. N. Senn.
Lecturer on Military Surgery, Dr. Solon Marks.
Lecturer on Surgical Anatomy, Dr. Wm. Mackie.
Lecturer on Descriptive Anatomy, Dr. Horace M. Brown.
Lecturer on Principles of Medicine, Dr. James Dorland.
Lecturer on Obstetrics, Dr. Robert Herdegen.
Lecturer on Gynecology, Dr. Wm. Fox.
Lecturer on Chemistry, Dr. A. B. Farnham.
Lecturer on Physiology, Dr. J. Bading.
Lecturer on Materia Medica, Dr. H. V. Ogden.

The Paris Obstetrical and Gynecological Society has just been organized (in Paris), with thirty titular and seventy associates and correspondents. M. Alphonse Guérin is President and M. Charpentier Secretary of the Society.

Prof. Jaeger's Successor.—Prof. Fuchs, of Liège, has been elected to the Chair of Ophthalmology in the University of Vienna. The election has not yet been confirmed, however, by the Minister of Public Instruction.

Porro's Operation was performed in Imola by Dr. Vincenzo Lesi, in the public hospital, on the evening of October 23d, upon a rachitic woman far advanced in pregnancy. Ten days following the operation, the woman was in good condition and with a temperature almost normal, and gave promise of speedy recovery.—*Gazetta Medica di Torino*, Dec. 1884.

Dr. Schweninger and the Berlin Medical Faculty.—There seems now a slight change of feeling by the public in favor of the faculty. In the higher circles of society, with which the Chancellor's office and Prince Bismarck himself are intimately related, the story has been lately circulated that the Chancellor has had only for a short time any knowledge as to the earlier record of Prof. Schweninger, and that it was a personal insult to the Prime Minister to insinuate that in the light of th s information he had elevated Herr Schweninger.

It is further asserted that the Chancellor has obtained the records of the courts concerning Herr Schweninger, and their perusal has exceedingly shocked him.

Incidental to the false report of Schweninger's appointment to the Ober-Stabsarzt, Bismarck is reported to have said in private circles that in view of the adverse circumstances, he could not understand how any one could imagine that he had appointed him to that body. To these expressions some significance may well be ascribed, though to infer certain victory for the faculty would be premature.

It is also reported that under the advice of his physician—Schweninger—Prince Bismarck will accompany his wife, who is ill, to the South, and that Prof. Schweninger will also go with them. This will be a convenient method of avoiding a distasteful discussion of the "Schweninger affair," which is imminent in the Reichstag. In the meanwhile, it is perplexing the profession in Germany to surmise who will be appointed to the now fatherless chair of dermatology.

The Suspension of the Publication of the Index Medicus.—We regret extremely to receive the following notice addressed to the subscribers to the *Index Medicus* accompanying the annual *Index* which completes the sixth volume of that publication:

"Notice.—With this issue, containing the title-page and annual index of Volume VI., the *Index Medicus* will cease to be published. During its six years' career, it has been supported by its special friends with a generosity perhaps unparalleled in the history of medical journalism. The publisher, the late Mr. Leypoldt, notwithstanding a heavy loss at the outset, and a but slowly diminishing annual deficit, maintained the undertaking with characteristic spirit and zeal. His successors, who are managing his estate and business enterprises, have made strenuous efforts to place the *Index Medicus* on a self-supporting basis, remembering with what particular favor Mr. Leypoldt regarded it. Their latest effort has been unsuccessful, and the few additional subscriptions which were required have not been obtained. The time has come, therefore, when neither zealous friends nor generous publishers can be allowed to make further efforts or sacrifices, and the publication is discontinued. Whether it will in some other shape, or under some other auspices, again appear, is for the future to decide.

"John S. Billings,
"Robert Fletcher,
"Editors."

Prof. Hyrtl celebrated, a few days since, his 74th birthday in full mental and bodily vigor. He was, on this occasion, the recipient of many congratulations from his friends, both at home and abroad.

Official List of Changes in the Stations and Duties of Officers Serving in the Medical Department, U. S. Army, from January 13 to January 19, 1885.

Promotions.

Campbell, John, *Lieutenant Colonel and Surgeon.*—To be Surgeon with rank of Colonel, December 7, 1884

Alexander, R. H., *Major and Surgeon.*—To be Surgeon with rank of Lieutenant Colonel, December 7, 1884.

McElderry, Henry, *Captain and Assistant Surgeon.*—To be Surgeon with rank of Major, December 7, 1884.

Appointment.

Kean, Jefferson R.—To be Assistant Surgeon with rank of First Lieutenant, December 8, 1884.

Bentley, Edwin, *Major and Surgeon.*—Leave of absence extended two months.—*S. O. 8, A. G. O.*, January 10, 1885.

Tremaine, W. S., *Major and Surgeon.*—Relieved from duty at Fort Porter, New York.

Girard, A. C., *Captain and Assistant Surgeon.*—Ordered for duty at Fort Porter, New York.

Appel, D. M., *Captain and Assistant Surgeon.*—Ordered for duty at Plattsburg Barracks, New York.

Girard, J. B., *Captain and Assistant Surgeon.*—Ordered for duty as Post Surgeon at Fort Schuyler, New York Harbor.

Havard, Valery, *Captain and Assistant Surgeon.*—On being relieved at Fort Schuyler, authorized to avail himself of leave of absence (four months).—*S. O. 8, Department of the East*, January 12, 1885.

Elbrey, F. W., *Captain and Assistant Surgeon.*—Sick-leave still further extended six months on surgeon's certificate of disability.—*S. O. 9, A. G. O.*, January 12, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLVI. SATURDAY, JANUARY 31, 1885. NO. 5.

ORIGINAL LECTURES.

SOME FORMS OF ORGANIC DISEASE OF THE HEART.

A Clinical Lecture, delivered at Bayview Hospital.

BY I. E. ATKINSON, M.D.,

PROFESSOR OF PATHOLOGY AND CLINICAL MEDICINE IN THE UNIVERSITY OF MARYLAND.

GENTLEMEN: This patient is a German peddler. He is seventy-three years old and a widower. He says he has always been pretty well until of late, when he began to have shortness of breath. He was able, however, to attend to his business until last Christmas. Pain in the chest and swelling of the legs then developed. Since that time he has been able to do no work. He entered the hospital June 10, 1884. He is rather small in stature and is emaciated. His face is deeply wrinkled, and the natural sallowness of his skin is combined with a duskiness that intensifies his expression of discomfort. *Arcus senilis* is well marked. His supraclavicular and suprasternal fossæ are depressed, but the lower intercostal spaces are widened. The thoracic parietes are seen to be almost motionless, his respiration being largely abdominal. His lower extremities are extremely anasarcous. His temperature is normal. His respirations are 24 to the minute with prolonged expiration. His pulse ranges between 90 and 100, and is weak, very irregular, and unequal. The artery is cord-like from calcification. The area of cardiac dulness begins at the fifth rib superiorly. Transversely, it extends from the left border of the sternum to an inch and a half beyond the nipple line. The cardiac impulse is felt in the fifth intercostal space, but is unusually widely diffused, and can be felt in the sixth interspace. Anteriorly, the pulmonary resonance is almost tympanitic, but is diminished posteriorly, on both sides inferiorly, and over the right scapular region there is decided dulness. A cardiac murmur cannot be detected; the valves close with a sharp, ringing sound. Auscultation of the heart, however, is rendered difficult by the dry and moist râles heard everywhere, in front and behind, except at the point of greatest dulness, where there is rude, almost tubular breathing, with increased vocal fremitus and resonance. For several months cough, with free mucopurulent expectoration, has been very annoying. Dyspnœa is very urgent. His tongue is slimy and moderately coated; his appetite bad; his bowels regular. His urine is acid, abundant, and slightly albuminous. He has never spat blood.

This case presents a most interesting train of symptoms. To account for the gradually increasing dyspnœa, we discover satisfactory evidences of cardiac dilatation, and yet the superior margin of dulness is on the line of the fifth rib, above which the note is even tympanitic. The breath-sounds indicate a general bronchitis, which, we find, has recently become aggravated. The slowness with which the lungs are emptied of air confirms the diagnosis of emphysema suggested by the tympanitic resonance anteriorly. Emphysema is a common cause of cardiac dilatation and hypertrophy beginning in the right ventricle; but here it is not sufficiently pronounced to enable us to speak with certainty. We miss the peculiar enlargement of the thorax so characteristic of hypertrophic emphysema. There can be no doubt, however, that this condition is present to a considerable extent. To whatever extent disordered, his heart seems to have served him pretty well until the infirmities of age began to overtake him, when, weakening and partaking of the fatty degenerations of which his arcus senilis is an index, it began to yield before the peripheral resistance and to dilate. The increased cardiac bulk is shown in the diffusion of the apex heat, though the emphysematous lung marks the upper border of its area. That this enlargement is due to dilatation, and not to true hypertrophy, we conclude from the diminished force of the beat and the irregular and uneven pulse. The sharp closure of the valves show that their office is properly performed. The heart fails to drive the blood through the arteries with sufficient force, and allows mechanical or venous hyperæmia to arise. The right heart, distended with the blood it cannot efficiently drive onwards, is unable to receive the full current from the systemic veins. Stasis thus produced is the cause of the throbbing jugulars (a sign often due, it is true, to tricuspid insufficiency), the cyanosis, the general dropsy, hepatic and renal engorgement, and consequent albuminuria. The left heart, also yielding before the increased resistance, becomes distended, and not only sends the current onward in diminished violence, but causes an engorgement additional to that already present in the emphysematous lung. In the present instance, the pulmonary engorgement seems to have produced an area of consolidation, the signs of which we detect over the posterior portion of the right lung.

Here, then, the cardiac disorder appears to be the important one. You have observed the constant and painful effort our patient is compelled to make in order to continue the struggle for life. Mark the contrast with our next case.

This young colored man is nineteen years old, of slender physique. He is a jockey. He was admitted September 16th, with syphilis. There are no signs of pulmonary, hepatic, or renal disease. He has never had rheumatism. His heart trouble was discovered in the course of the examination, and seems to have occasioned no discomfort whatever. Careful examination is required to detect the cardiac murmur, which can only be heard in the nipple line over the sixth intercostal space. It is a faint, systolic bruit. There is little or no cardiac hypertrophy. I am unable to say exactly why the murmur is only heard at the point indicated. It is not anæmic, because it is apical. Unless it is due to some irregularity of closure of the mitral valve,

through imperfect action of a papillary muscle, it is caused by disease of the mitral valve with regurgitation. It is of such small intensity that the boy is still able to run up-stairs and to attend to ordinary duties without inconvenience. Whatever the degree of insufficiency, we may be sure it is compensated for by slight, though imperceptible, cardiac hypertrophy; the bearer is unconscious of a defect. I show the case to illustrate the small inconvenience a slight valvular disorder may occasion, and how, so long as it is not progressive, the heart is able to compensate for the damage.

The next case is that of a Maltese sailor, of peculiarly effeminate appearance; professedly twenty-five years of age, but looking much older. He was admitted April 28th. He informs us that his general heath was pretty good until about one year ago, when he caught cold at sea, since when he has never been well. As you see him, he has that pallor and puffiness of face that are so often seen in certain cases of renal disease. He has extensive general anasarca and ascites. He is profoundly anæmic and debilitated, and suffers from frequent headache, indigestion, and pain in the lumbar region. He has pronounced albuminuria, and tube-casts are abundantly present in his urinary sediment. In a word, his history for the past eighteen months is that of Bright's disease, beginning probably as a diffuse tubular nephritis. My special object in showing him today, however, is to speak of a cardiac valvular trouble that is probably consecutive to his renal disorder. Over the second right intercostal space, close to the sternum, one hears distinctly a diastolic murmur. This is audible over only a limited area, not larger than a silver dollar in surface. The heart-action is slightly excessive, and the apex beat, though in the fifth intercostal space, is almost in the nipple line. We thus recognize regurgitation of blood through the aortic valve with slight cardiac hypertrophy, but we look in vain for the train of symptoms that are usually associated with advanced cardiac disease, associated with aortic regurgitation, symptoms that are unusually well marked in our next patient.

John S., an unmarried German baker, twenty-three years old, was healthy until his sixteenth year, when he had rheumatic fever. He has never felt well since, though he has never again had rheumatism. He was able to work at his trade, however, until this summer, when he gave up, and was confined to his bed for nine weeks on account of his heart trouble. He is of muscular frame. Observe him attentively, and you will notice a violent pulsation over his heart and subclavicular region. Indeed, you may detect pulsation in his upper extremities and head, wherever his larger arteries become superficial. His heart apex beats in the fifth intercostal space, but one inch beyond the nipple line. The area of cardiac dulness merges into a flatness due to a moderate pleural effusion which, in the axillary line, is level with the seventh rib, and, posteriorly, with the angle of the scapula. A distinct bulging is seen over the cardiac region. The circumference of his chest is 17½ inches for the right, and 18½ inches for the left side at the nipple level. Splenic and hepatic dulness are very slightly increased. The temperature is normal. The pulse-rate is 86. Here, however, we notice striking peculiarities. The cardiac impulse is felt to distend the vessel with suprising violence, but, at the very moment of the shock, the artery falls away from the finger, as if exhausted at the first onset. The pulmonary auscultatory sounds are normal, with the exception of those indicative of left pleural effusion; but the cardiac sounds are greatly altered. At the apex a loud, blowing systolic murmur is heard, and at the base there is a pronounced double murmur, running at the systole into the common carotid arteries. There is no dropsy, no albuminuria. The appetite is good, the tongue clean, the bowels regular. Contrary to what might have been expected, sleep is good, and without troublesome dreams.

We have here a cardiac disease of rheumatic origin, having begun probably in the aortic valve, as a regurgitation. With the progress of valvular disease, stenosis eventually developed, and the very great hypertrophy of the left ventricle that always reaches its highest grade in aortic disease. The intensity and diffusion of the basic systolic murmur prevent our deciding whether it is it that we hear at the apex or a true mitral regurgitant murmur.

The effect of the cardiac hypertrophy is seen in the greatly increased pulse-wave, while the pronounced regurgitation causes the sudden collapse of the artery. The result is the "water-hammer," or "Corrigan's," pulse, that is itself diagnostic of the cardiac disorder we are now considering. Why did we not observe a similar combination of symptoms in our preceding case, in which aortic regurgitation is well established? Simply because the lesion has not been long enough present. The area of the murmur is very circumscribed, showing a less intensity than in our present case. The aortic regurgitation has been established too recently, and is of too limited extent, to produce the highly characteristic symptoms we observe here. Should he live long enough, they will become developed.

These cases represent, each, a different form of cardiac disorder. Their exciting causes are probably different. This elderly man, our first patient, whose venous system is engorged with the blood his feeble heart allows to accumulate, suffers from such dyspnœa that his every breath is an effort. We know that his distress might be alleviated, could we but restore to his heart its normal force and activity. Our remedies, therefore, shall be such as tend to add to this organ new power, evanescent though it must be. We can stimulate the cardiac innervation, and in gaining temporary power, may hope to overcome for a time the engorgement, with its consequent œdema. Our efforts in this direction will be assisted by the judicious employment of drastic cathartics and diuretics. To stimulate his heart, and to enable it to hobble along to better purpose, we order alcohol, in small doses, and the carbonate of ammonia. To secure copious watery stools, we employ the compound jalap powder in drachm doses, as occasion requires. As a diuretic, we can give nothing so good as digitalis, of which he will take the infusion in half fluidounce doses thrice daily. Exactly how digitalis acts in these cases, is not known; but it is certain that in passive engorgement with dropsy from the weakened hearts of elderly persons, its judicious employment will often restore to comfort those who seemed to have been already pressed by the hand of death; whether it is by increasing heart-action, which,

in view of recent experiments, seems doubtful, or by restoring regularity of heart-action by increasing arterial resistance, or as a simple diuretic, we cannot say. The necessities of his condition will teach him the mode of life most calculated to be of benefit, and he will be made to follow appropriate rules of diet and general behavior.

Our second case needs no special treatment. He is conscious of no discomfort; and for the present, the slight valvular defect finds compensation in slight hypertrophy, and an equilibrium may be maintained for many years. By injudicious interference, much damage might be done. The patient whose cardiac disorder is consequent upon Bright's disease, requires treatment addressed almost exclusively to his renal and general condition. By relieving the disease of his kidneys, we lessen the intensity of the exciting cause of his heart trouble, and alleviate the peculiar vascular alterations that so constantly provoke cardiac hypertrophy. The aortic regurgitation will call forth such increase in muscular power as will, for the present, provide for the shortcomings of the valves.

Our fourth case appeals strongly to our sympathies. The valvular disease, probably of years' standing, has been surely and steadily progressive, and has all the time been provided for by increasing cardiac hypertrophy. These are signs that before long the valvular disorders will outstrip the compensating hypertrophy, or that the excessive demands made upon the heart muscle will result in its atrophy and dilatation to such an extent that finally the impairment to the circulation will lead to a fatal issue, which is more apt to occur suddenly in this than in other valvular defects. What can we do to assist the conservative efforts of nature? Indeed, very little. There is no need of cardiac stimulants, his heart already beats with most unusual violence. Should his heart begin to fail, it will then be the time to employ them. We can give no drugs that can arrest the gradual advances of the processes that are working out his destruction. We can guard him against a recrudescence of his rheumatic disorder, or of complicating maladies, by proper hygienic surroundings. You will have observed that these patients do not suffer from apprehension and general anxiety of mind, such as are so often experienced in persons with purely functional cardiac disorder. This is not uncommon. Indeed, you will often detect advanced organic disease in those who have little or no suspicion that their hearts are not in perfect order.

SURGICAL OBSERVATIONS IN THE TREATMENT OF THE DISEASES AND ACCIDENTS OF THE LIVER.[1]

BY CHARLES K. BRIDDON, M.D.,
OF NEW YORK.

UNTIL within a recent period, the liver and its annexa have appealed in vain for the help accorded to its neighbors in the abdominal cavity. Such aid has been restricted to the treatment of abscess and hydatids. The frequent occurrence of suppurative hepatitis in the tropics, afforded opportunities for clinical study that led to the early recognition of indications for the prompt and early evacuation of cavities resulting from that disease. Thirty years ago, Budd, in his monograph on diseases of the liver, expressed himself as follows: "From what I have seen and read of hepatic abscess, it seems to me that the proportion of recoveries has been just as great, or even greater, when the abscess has opened into the lung or the bowels as when it has made its way through the side, and I can only explain the circumstance by the fact that, when an abscess has pointed at the side, it has seldom been allowed to open of itself. When the abscess is large, and has existed long, its walls are thick and unyielding, and it has in consequence still less disposition to close up. When an abscess of this kind opens of itself, either outwardly or into the intestine or lung, matter continues to be discharged, and the patient generally dies, worn out by the protracted suppuration. When the abscess is opened by the knife, the same thing, of course, happens, and the patient dies the earlier for our meddling. In India now, it seems to be the common practice to thrust a long exploring needle into the liver where the presence of an abscess is suspected; and now and then, perhaps, the disease may be cured in this way. A single abscess may be opened when it is of moderate size, and before its walls are too thick and firm to close together, and the cavity may be thus obliterated. But there are many objections to the practice that to me seem quite decisive against it. First, there is the danger of hemorrhage, and of setting up fresh inflammation by the mechanical injury thus done to the liver. This danger may, perhaps, be small for a single puncture; but if the abscess be deep-seated, it may not be hit at the first thrust. Again, from the difficulty of distinguishing the different diseases of the liver, if the operation be commonly adopted, it must often be performed where there is no abscess at all. It will readily be imagined that much mischief may be done in this way. Often, too, there is more than one abscess. This was the case in thirteen of the twenty-nine cases recorded by Annesly, and in still larger proportion in the cases collected by Andral, and Louis, and myself. We can hardly hope to reach all the abscesses; and unless we do, we cannot cure the patient. Then there is the danger, that has been before alluded to, of letting the matter escape into the peritoneum, and setting up peritonitis that may be speedily fatal. An occasional instance of success will, I fear, be a poor set-off against the cases in which the operation has done mischief, or failed of doing good."

Such was the doctrine enunciated by a writer that was recognized as an authority in 1852. We shall see how the improvements in modern treatment have swept away most of these objections, although, at the same time, we are bound to give due consideration to opinions based upon the study of a large number of cases. That the sudden evacuation of such abscesses is apt to be followed by considerable hemorrhage from the granulations that line its interior, we are well aware, but that it is apt to be of a serious character is extremely doubtful. At all events,

[1] Read before the New York Surgical Society, January 13, 1885.

it is probable that the benefit derived from such evacuation will outweigh the loss of blood. The character of the tissues in which such cavities are formed is opposed to their contraction, and the surrounding structures are very likely to resent interference by extension of inflammatory processes that may perpetuate the conditions already existing, or lead to the formation of suppurative foci in the neighborhood, or even to necrotic processes of a serious character. Most of these conditions which are referred to as complicating incision or puncture, will occur when a spontaneous opening forms. It is true that such an opening is usually minute, and permits a very gradual discharge of the contents, but without antiseptic appliances it would be impossible to keep such a cavity aseptic, and such a condition would cause bad local reactions, to say nothing of the danger of general infection. Then, again, to open through the abdominal or lower thoracic walls, occupies a considerable period of time, during which the abscess itself is enlarging, and the patient himself becoming more exhausted. I think that where we find a large number of small collections of pus scattered through the liver, with one large central abscess, that the histories of such cases, and the post-mortem investigations, go far to prove that the small collections are secondary to the large one, which would be an indication for early operation, and I certainly cannot see that the existence of other collections should contraindicate an operation on an abscess that is fluctuant and approaching the surface. Of course, I am not referring to the multiple abscesses that are found in pyæmia. A man entered the service of the Presbyterian Hospital on the 20th of August, 1883, with a large hard tumor situated in the epigastric and right hypochondriac region. It was prominent in front, and over the centre was a spot two and a half inches in diameter, that was exceedingly tender, and the seat of obscure fluctuation. His general condition was bad. On the 22d, the aspirator was used, and three ounces of pus were withdrawn. On the 25th, the operation was repeated, and the same amount of pus was obtained. On the 27th, he was very restless, sweat profusely, and complained of severe epigastric pain. Sept. 2d, he vomited a good deal of glairy mucus. On the 5th, he had diarrhœa, and the excreta were mixed with blood and pus. The diarrhœa continued, and he died on the 12th of gradual exhaustion. At the autopsy the principal lesions were found in the liver, although there were also found evidences of chronic diffuse nephritis. The liver was found to be the seat of multiple abscesses. The lower border of the right lobe was found adherent to the abdominal parietes. At this point was a large abscess which communicated with the commencement of the duodenum by a ragged opening, which was cut off from the abdominal sac by adhesions of the parietal and visceral peritoneum. It is probable that these smaller abscesses were secondary to the large one, and it is probable that an early operation might have prolonged the man's life.

The dread of opening the abdominal cavity in an attempt to reach an abscess of the liver, for a long time deterred medical men from operating; much time was lost in studying the physical signs that indicated the formation of adhesions. Then Graves made an advance in the right direction, practising an incision over the most prominent part of the tumor down to the peritoneum, filling it with lint, and thus diminishing resistance and inviting a spontaneous discharge. At a later period Recamier advised opening the abscess from without inwards, by the successive applications of potassa fusa, a very slow and painful process. In 1842 Murray called attention to the advantages derived from the method by puncture, insisting that the introduction of an ordinary sized trocar and canula, leaving the latter in position until adhesions formed between the liver and abdominal wall, and that this does occur in the large majority of cases there can be no doubt. In fact, Jameson (*Lancet*, April 29, 1871) demonstrated such to be the fact in a case in which the patient died on the fourth day after the operation, and in which the parts were found adherent around the artificial opening for a breadth of one and a half centimetres.

With improved methods of treating such conditions, we are warranted in anticipating more favorable issues in the future. In 1883, Lawson Tait reported four cases of hepatotomy, in which the existence or non-existence of adhesions were not considered. Three of these were cases of hydatid disease, and one was for large abscess. In all of them incisions were made through the abdominal wall, exposing the cyst, which was then opened and attached to the margins of the external opening by suture. All of these cases recovered completely. The great advance made by the author of these operations was in attacking the disease by a systematic procedure, without regard to adhesions.

Conditions of the annexa of the liver calling for surgical interference are very various, but most commonly due to stenosis and occlusion of the biliary excretory ducts. Simple dilatation of the gall-bladder is associated with obliteration of the folds that are characteristic of its lining membrane, and thinning of its walls. It may attain an enormous size, but generally maintains its natural form. It is not generally adherent to surrounding parts, and contains only more or less bile-stained mucus.

Empyema of the gall-bladder is not attended with change in form, but only in size. It may be free, or united to surrounding parts by firm fibrous adhesions; the walls have become friable, and are easily lacerated. Recoveries from simple dilatation are common enough. The obstruction may cease to exist, especially if due to calculus in the common or cystic duct; and on the removal of this, the inflammatory processes in the gall-bladder speedily disappear. In other cases, the disease progresses steadily, exposing the patient to the dangers of ulcerative perforation or rupture. Especially is this apt to happen in empyema due to gall-stones. In some cases it has been noticed that very marked changes occur in the size of the distended gall-bladder, due to calculi acting as gall valves. A well-marked and interesting case of this kind entered the Presbyterian Hospital, June 28, 1880. The patient was a widow, 45 years old, who first began to suffer from pain in her right hypochondrium, four years

before admission. Eighteen months before, she began to have unusually severe paroxysms of pain, that were preceded by chills and fever, and these attacks were repeated with intervals of eight or nine days. On admission, she was found to be deeply jaundiced, had white stools, and high-colored urine; complained of pain, pruritus, and occasional vomiting. There was marked tenderness over the epigastrium; the liver was enlarged, measuring six inches in vertical line; its free border could be felt free from any irregularities. Day after admission, she had one of her attacks, beginning with chill, followed by exaltation of temperature. She suffered from intense pain, and the gall-bladder could be felt distinctly below the free border of the ribs. After this the paroxysms occurred about once a week. It was observed that the gall-bladder became more and more dilated before and during the attacks, with increase of the jaundice to bronze color; and that on subsidence of the pain, the size of the gall-bladder diminished and the jaundice became lighter in color. It was thought that the obstruction was due to calculus in the common duct; that when this became dilated it permitted the calculus to recede, and the contents to escape; that when the dilated duct emptied itself it grasped the stone and closed the duct. After lingering until September 30th, she died from profuse diarrhœa and exhaustion.

The autopsy was made thirteen hours after death. The portal system was found distended with blood. There was no fluid in the cavity of the peritoneum. The stomach and duodenum were opened *in situ*. On the inner surface of the latter was a prominent conical projection, on the apex of which was the opening of the common duct. Pressure on the gall-bladder caused an escape of bile from this orifice. A probe passed through it entered a large ampulla, which, on further examination, was found to be the dilated duct continuous with a cavity in the substance of the liver itself, and probably caused by ulceration of the walls of the duct by the pressure of a calculus which had recently escaped into the intestine. The two ducts which unite to form the main hepatic duct were each distended by a calculus as large as a good-sized marble. There were several small abscesses in either lobe, and the left lobe was larger than the right. In this case, all those conditions which it would have been possible to recognize during life would have warranted an operation, and yet the pathological lesions found after death would seem to prove that such a procedure would have done no good. The abscesses were no doubt secondary to the ulceration in the walls of the common duct.

The operation of cholecystotomy was first proposed by Jean Louis Petit (*Memoires de l'Acad. de Chirurgie*, tome i. page 155); afterwards, and independently, by Dr. Handfield Jones. It was first performed by Dr. Bobbs, June 15, 1867, then by Dr. Marion Sims, Ransohoff, and a number of European surgeons, and it may now be fairly said to be one of the recognized operations in surgery. But from the nature of conditions that not infrequently complicate it, it must often fail. It will frequently happen that the calculi are inaccessible, hidden in recesses and diverticuli that cannot be reached, and that such circumstances will render it impossible to complete an operation justified by all the symptoms that could be made out during life. The steps of the operation will be similar to those used in gastrotomy. The careful introduction of each interrupted suture through skin, parietal and visceral peritoneum, and incision immediately following fixation, has been followed by the best results. Circumstances might present themselves that would render it advisable to open the gall-bladder before attaching it to the abdominal wall. In attaching the walls of a cavity distended to its utmost, a faulty needle, with cutting edges, might easily penetrate through all the tunics that enter into the composition of its walls, and permit a leakage sufficient to excite peritonitis of a fatal character. If such conditions should appear to warrant incision previous to suture, it would be proper to use Keen's scoop, or to empty and disinfect the cavity through the medium of an aspirator.

Ruptures of the liver, generally fatal, are more immediately concerned in the subject of this paper. Most frequently the result of severe accidents, they are attended with marked symptoms of collapse, sometimes with local conditions that may indicate the existence of abdominal hemorrhage. More frequently the patient dies speedily, and in the majority of the cases that I have seen, the lesions have only been suspected during life, but I think that in the future the diagnosis will be made during life by explorative operations.

Five years ago I saw a youth who had been thrown from a wagon a month before my visit. He came in violent collision with a lamp post, but soon recovered from shock. His physician informed me that for several days there were no symptoms of serious mischief, but that after the first week there slowly developed tenderness and swelling in the right hypochondriac region. I found him with a much distended abdomen, dull on the right side, and resonant on the left. The dulness on the right was continuous with the usual area of liver dulness, and reached downwards nearly to the iliac fossa. The swelling was fluctuant, and had been emptied more or less completely on several occasions by the physician in attendance, and on the day of my visit a large amount of apparently pure bile was removed by the aspirator. There were no symptoms of obstruction present, and it was the opinion of the physician that rupture had occurred, and that the bond of union had yielded slowly to the pressure of the ducts, forming an adventitious cyst. Subsequently a large opening formed, which drained off large quantities of bile, and he succumbed at last to the drain upon his system. Unfortunately the case is not complete. I saw him only once, and efforts to obtain an autopsy were of no avail.

The following case of injury occurred in my service, and is of considerable interest in several respects (reported by Charles G. Wagner, House Surgeon):

Charles McHugh, 29 years old, native of Ireland, was admitted to the Presbyterian Hospital in the City of New York, July 3, 1883, service of Dr. Charles K. Briddon, with the following history:

While under the influence of liquor, and attempting to work at his trade as a bricklayer, he lost his

footing and fell from the third story to the cellar bottom, landing on a pile of bricks. When he was admitted to the hospital he was in a condition of profound collapse, which lasted for some considerable time. As soon as he was able to respond to interrogations, it was ascertained that he was suffering from severe abdominal pain, concentrated principally in the right hypochondriac and lumbar regions, and in the right scapulo-humeral articulation. His condition was such at this time as to preclude any very exact physical exploration, but no crepitus could be made out in the neighborhood of the shoulder. His temperature was about normal, his pulse frequent and thready.

On the following day the signs of shock were still present. It was noticed that all the urine that he had passed was bloody, the abdominal muscles were tense, and there was a manifest swelling between the cartilages of the ribs and the right iliac fossa, which region was exquisitely tender to the touch. Temperature 103°, pulse 120.

A week elapsed before the symptoms of shock had entirely passed, and during this time there was a gradual abatement of the local signs, the pain diminished, the abdomen became less tense, and there was an obscure fluctuation in the hypochondriac and anterior lumbar region. Urine still continued bloody.

July 25.—Three weeks after the injury was received, the blood had entirely disappeared from the urine; patient complained of much difficulty in breathing and pain in the side; there was some diffused abdominal tenderness, but it was still principally concentrated in the right side. There was absolute dulness from the nipple line to a level with the anterior superior spinous process of the ilium, and below the free border of the ribs fluctuation was manifest. Believing that the collection of fluid originated in the kidney, and that it was confined by a capsule formed out of connective tissue, it was determined to explore it with a needle. The puncture was made a little below the free border of the eighth rib, and on connecting with Dieulafoy's apparatus, sixty-nine ounces of fluid were removed. It had all the characteristics of pure bile. The chemical analysis and the microscopic appearances confirmed that opinion.

Patient was very much relieved by the operation. The difficulty of breathing and pain almost entirely disappeared, and his temperature dropped to nearly the normal. This condition was maintained until the evening of the following day, when the patient had a chill, which was followed by elevation of the temperature to 103°, pulse 136, respiration 36. In this short time the sac had refilled, the physical signs were as before, and he complained much of the pain and difficulty of breathing; his face was somewhat flushed, and there was a perceptible yellowish tinge of the sclerotics.

On the 27th, his symptoms were of such an urgent character as seemed to demand either aspiration or free incision, and the latter was determined upon. His condition did not appear to warrant the use of an anæsthetic. An incision one and a half inches long was made below the free borders of the eighth and ninth ribs, not being certain whether the fluid was contained within the dilated gall-bladder or an adventitious cyst. The dissection was carried carefully through the abdominal muscles until the cavity was reached. The peritoneum was not opened. A large gush of bile escaped, and seventy-five ounces were collected. As soon as the opening was made, the index finger was introduced, and wherever it could reach so as to come in contact with the walls, the cavity appeared to be lined with a perfectly smooth surface. No blood and no coagula escaped. Of course, the finger was too short to map out the confines of the space. After it was emptied, another attempt was made to explore with the finger, but it was found that the internal aperture was blocked by a solid mass that moved upwards and downwards with the movements of respiration. On passing the finger downwards, it could be passed under this mass, which was made out to be the liver, which probably had been pushed up by the accumulation, and which had gravitated downwards on its removal. A large drainage-tube was fixed in position, and a dressing of carbolized gauze.

The operation gave prompt relief, and it was of course more permanent in character than the aspiration. A free discharge of bile occurred, necessitating frequent changes in the dressing, with occasional fluctuations as regards quantity. The discharge continued for several weeks. For the first few weeks it was apparently mere bile unmixed with other secretions. During this time the bowels were constipated, and the dejections were clay-colored, and, on one or two occasions, there was a slightly perceptible yellowish hue of the skin, but at no time amounting to jaundice, and there was not any marked emaciation.

On the 22d of August, during the absence of Dr. Briddon from the city, the patient accidentally removed the drainage-tube. A new one was introduced, and simple dressings to the opening, which only gave exit to a moderate amount of pus. On removing the dressing on the following day, the tube was missing, and could not be found. It was of ordinary soft rubber, a quarter of an inch in diameter, and eight inches long. It was supposed to have disappeared into the cavity of the wound, and it is possible that it might have been drawn into it by the suction movement of inspiration. At all events, it could not be found. After ineffectual efforts to recover it, the patient's temperature rose to 105°, where it remained for a few days, and fell again to the normal.

On the return of Dr. Briddon, August 2d, a tupelo tent was introduced for the purpose of dilating the sinus so as to permit of a more thorough exploration of the part. The patient took this out without permission, stating that he could not tolerate the pain caused by its presence. He had another rise of temperature. In fact, it appeared that any interference with the interior of the cavity was resented by a febrile movement. The treatment at this time consisted in daily irrigations, variously medicated—at one time with boracic acid, and subsequently with tincture of iodine.

About the middle of November, four months after the injury was received, patient began to have severe attacks of coughing, and there were some physical

signs of a suspicious character to the right of the right border of the middle of the sternum. These signs were thought to indicate the existence of a cavity. The attacks of coughing were always brought on during the process of irrigation; and on several occasions when iodine was used, the patient said that he could taste it in his mouth. It appeared probable that adhesions had formed between the lung and diaphragm on the one side, and that perforation of the latter had permitted the contents of the sinus to reach the lung itself. It was considered as extremely doubtful whether any drainage-tube had receded into the wound. It was, however, deemed proper to endeavor to make a more free exit for the discharge of anything that might be found about the diaphragm. There was no collection of fluid in the cavity of the pleura at any time.

November 27th, the patient was etherized, and the superficial portion of the sinus was gradually dilated, first with sounds, and then with the finger. It appeared to pass directly upwards, almost in contact with the inner surface of the ribs; at a distance of about three inches from the surface, the finger engaged in a narrow, constricted portion, and on forcibly dilating this passed into a larger cavity, apparently above the diaphragm. It was noticed at this time that there was some bloody froth in the mouth of the patient, and it was regarded as evidence that the opinion as to probable communication between the original cavity and the tubular structure of the lung was correct. A very faithful search was made for the missing drainage-tube with every conceivable form of forceps, and with wire snares passed through cut-off catheters, but without result, and it was considered as scarcely possible that it could have escaped being found. Two large drainage-tubes were introduced side by side, and the wound was dressed as before. This operation was followed by less reaction than was expected, and after a few days there was a manifest improvement in his condition. His cough entirely ceased, the discharge diminished in quantity, he gained flesh, and in about six weeks, though the discharge still continued, he asked for and obtained his discharge.

He was again seen about the middle of May, 1884. He was in very good general health, and had been working at his trade without inconvenience, still wearing the tube through which there was a little discharge.

HYDROCHLORATE OF HYDRASTINE,

A SOLUBLE SALT OF THE WHITE ALKALOID OF HYDRASTIS CANADENSIS; ITS APPLICATION AND VALUE IN OCULAR THERAPY.

BY ROBERT SATTLER, M.D.,
OF CINCINNATI, OHIO.

THE well-known application of the preparations of hydrastis canadensis as therapeutic agents for the various affections of mucous surfaces, induced me, several years ago, to test its efficacy in the management of catarrhal processes of the nose, retropharyngeal space, and pharynx, which constitute in so many cases the primary or causative lesions of middle ear disease.

Although a fair and extended trial was given the remedy, which was resorted to in various forms of solution, and by various methods of application, I abandoned it, principally on account of the staining of towels and handkerchiefs which followed its local use and also for the reason that I became convinced that similar good results could be obtained in this locality from other remedies, with less objectionable consequences to the patient. Impressed, however, with its usefulness as a local stimulant to the vascular and secretory portions of the mucous membranes and therefore applicable in both the dry and hypertrophic forms of catarrhal inflammation, I determined to await the appearance of more satisfactory preparations of the drug and to renew at some future time a series of observations.

Several weeks ago, my friend Prof. J. U. Lloyd sent me several, to me altogether new, preparations of hydrastis with the request to test their therapeutic value in those affections in which the drug would appear to me indicated or applicable, and to furnish a brief summary of results for his work on *Drugs and Medicines of North America*.

At my request, two, four, and five per cent. solutions of the sulphate of berberine and of the hydrochlorate of hydrastine, the two alkaloids of the hydrastis canadensis, also the sulphate of berberine and hydrochlorate of hydrastine in powder form were furnished, and a series of observations, carefully recorded by my assistant, Dr. C. H. Castle, were at once commenced at my clinic.

The use of the berberine solutions proved of so little advantage and was so uniformly attended by so many disadvantages when used in the form of collyria, owing to the marked staining of the adjoining cutaneous area and the immediate precipitation or chemical transformation of the mucous secretions, that it was abandoned. The use of solutions, and particularly the insufflation of the powder into the bottom of the external auditory canal, was followed by the same unpleasant results—*i.e.*, staining, no appreciable effect except coagulation or firm incrustation.

The solution of the hydrochlorate of hydrastine, a white, colorless, and readily soluble salt, which differs from and is superior, on account of its soluble property, to the ordinary commercial, yellow, insoluble, so-called muriate of hydrastine (muriate of berberine), yielded different and far more satisfactory results.

A two or three grain solution of this salt, dropped into the conjunctival sac of the healthy eye, produces immediate local evidences of irritation and stimulation, which involves, to a greater or lesser degree, the entire ocular, palpebral, and reflected divisions of the membrane. It is attended by a subjective feeling, variously described as stinging, burning, or scratching and excites more or less blepharospasm and lachrymation. The discomfort following the instillation, although pungent while it lasts, does not exceed a minute's duration, and ceases abruptly; more or less moisture of the lid margin and flakes

near the inner canthus, are the evidence of the stimulant irritation of the conjunctiva.

Stronger solutions excite a correspondingly marked local reaction, more prolonged discomfort, intensified reflex symptoms and greater flow of watery mucus. The agent seems to exert its influence exclusively upon the conjunctiva.

This local action established, it was resorted to in those affections of the conjunctiva in which a temporary, more or less pronounced hyperæmia is necessary to aid in or accomplish the absorption of infiltrated cellular or other inflammatory elements; follicular conjunctivitis, also in the second and third stages of granular conjunctivitis, and in another large class of cases eminently chronic, tedious, and annoying to both physician and patient; chronic catarrhal conjunctivitis attended by the usual local alterations and modification or suspension of function of the secretory structures of the conjunctiva. Weak solutions were instilled into the conjunctival sac three or four times a day. In several cases, a ten and a twenty grain solution were applied, in addition, to the everted lids, and washed off with water and brush.

The results in all cases of follicular conjunctivitis may be considered satisfactory. The discomfort following the instillations was less severe than after the use of mineral or vegetable astringents, or mercurial stimulants of the same strength. The desired object—prompt stimulation, active hyperæmia, irritation of the circulatory and glandular structures—was accomplished with less discomfort to the patient and a more tonic and stimulant local effect.

In the chronic granular and other catarrhal forms, the results were also satisfactory. In the purulent forms of infants, weak solutions were substituted for the customary alum. et potass. sulph. and carbolic acid solutions, and used at short intervals, but the topical application, once a day, of an argentum solution was continued.

Briefly reviewing the results, based upon the observation of a number of cases, it can be said that the white or soluble hydrochlorate of hydrastine is of value as a local tonic, stimulant, and irritant to the conjunctival membrane and that it neutralizes or transforms chemically the altered secretions in the various other catarrhal processes and catarrhal stages of more serious lesions, and on this account is a valuable and reliable substitute for the various other stimulants and astringents. In many cases also, in which a simple tonic or stimulant effect is desired, with the least discomfort to the patient, it possesses advantages and is therefore entitled to preference.

I desire to add that my experiments were made with the hydrochlorate of hydrastine and not with hydrochlorate of berberine. In commerce, the substance sold as hydrochlorate (or muriate) of hydrastine is in reality a salt of berberine, the yellow alkaloid, and prescriptions are likely to be compounded of the berberine salt, even though muriate of hydrastine is specified.

Prof. F. B. Power recently contributed an interesting paper on the chemistry of hydrastine to the American Pharmaceutical Association, and No. 4 of *Drugs and Medicines of North America* is devoted to a study of hydrastine and berberine.

CAFFEINE AS A CARDIAC STIMULANT.

BY EDWARD T. BRUEN, M.D.,

ASSISTANT PROFESSOR OF PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA, AND PHYSICIAN TO THE PHILADELPHIA HOSPITAL, ETC.

CAFFEINE has been used for some years in various combinations and for a variety of purposes. I do not think, however, that it has been as widely employed for its action upon the heart as its good effects in the hands of those who have prescribed it would warrant.

The operation of this drug augments the volume of the pulse and increases the urinary secretion, and it possesses no cumulative effect even in repeated doses.

Experimental evidence upon the frog seems to refer the physiological action of caffeine to direct stimulative operation upon the cardiac muscle, increasing the energy of the systoles, and also regulating their rhythm. In a recent article in the *Therapeutic Gazette*, November, 1884, by Dr. Dujardin-Beaumetz, the history of this drug has been concisely reviewed. The substance of the observations of Trousseau, Rognetta, Dettle, and others claims the action of caffeine as accelerating the pulsation of the heart; while Caron, Meplaine, and Fossagrives assert that it slows the pulsations of that organ. Dujardin-Beaumetz also shows that caffeine was used by Zwinger, a Dutch physician, in 1725, in dropsy, and recently by Jaccoud and Gubler, who held that this drug is an ideal diuretic, not only in diseases of the heart, but also for the treatment of renal diseases with albuminuria.

My purpose is very briefly to relate my experience in its use after an extended trial of the drug. Granted the most satisfactory action of caffeine as a diuretic, like digitalis secondarily through its action upon the circulation, let me draw especial attention to its operation as a cardiac tonic.

Like digitalis, it is capable of producing a profoundly efficient stimulative effect even in advanced stages of cardiac degeneration. It is even more potential than digitalis in cases of extreme heart disease, in which digitalis frequently fails. It is difficult to explain this clinical fact since caffeine does not affect the vaso-motor nerves, a lack of which influence sometimes accounts for the failure of digitalis. More probably the superior action of one or the other drug in the above cases is merely a manifestation of the advantage of employing a new stimulant when the cardiac nerves have become insensitive to an influence of the same nature.

In my experience, caffeine has no influence as a cardiac regulator which is comparable to digitalis. This is unfortunate, since it is undesirable to combine digitalis with caffeine, because the preponderating effect of digitalis is also as a cardiac stimulant, not regulative; moreover, we use caffeine usually only in cases in which digitalis has failed. The most effective combination with caffeine to secure its operation as a cardiac regulator, is strychnia. This drug, by stimulating the vaso-motor and respiratory centres, and possibly also the pneumogastrics, sometimes is a most desirable adjuvant to caffeine. It is also serviceable after the use of caffeine has been discontinued,

for the latter is a remedy which is not suitable for prolonged employment as a cardiac tonic. The vascular system seems to grow accustomed to its operation, or even more frequently gastric irritation or dyspepsia necessitates its withdrawal. This objection cannot be urged against digitalis. Belladonna and convallaria come next in order as supplementary drugs.

The chief objections to the administration of caffeine arise from the gastric irritation, pain, and vomiting, which it occasionally provokes. This complication is not constant, but seems to present itself and contra-indicate caffeine in the same case in which the drug can be used with impunity at some other time. Symptoms of gastric irritation may appear even when caffeine is employed in small doses as well as in large, and compels its suspension or use by the hypodermic method. Toxic effects, such as confusion of the head with giddiness, have been mentioned by German authorities, but these complications have not embarrassed me.

I have found the most useful dose of caffeine has been four grains, administered three times daily. Sometimes, however, two grains, three times daily, have been sufficient, and in no case have I given more than fifteen grains per diem, my rule having been to use the smallest amount of the drug which would develop its characteristic action.

Abroad, very much larger doses seem to have been employed with impunity, and apparent benefit. Dujardin-Beaumetz observes that the good effects of the drug, when asystole is threatened, cannot be said to be exhausted unless ten grains, three times daily, have been employed. Carl Becker and Riegel (*Wien. med. Blatt.*, 5, 15, 1884) assert that even larger doses have been used without disagreeable consequences. I believe that unpleasant gastric symptoms might be expected if such large amounts should be prescribed. Caffeine should always be administered, not its so-called citrate. The basic properties of the drug are very weak, and, properly speaking, acetates, lactates, or citrates of caffeine do not exist. Mr. Llewellyn, of Sixteenth and Chestnut Streets, has prepared for me a number of solutions of the drug, but has found that caffeine, or its citrate, cannot be given even in the proportion of a grain to the drachm of distilled water without precipitation. But two or four grains of these substances, with an equal amount of benzoate of soda, can be readily given as in the following formula:

℞.—Caffeine,
Sodii benzoati, ... aā gr. xv.
Elix. aurantii,
Aq. dest., ... aā ℥ij.
Sig.—Teaspoonful dose.

The drug is, however, very efficient when used in pill form.

I append a few cases which illustrate the extensive possibilities of caffeine:

CASE I.—A vigorous man of 23, ruddy complexion, in the habit of using alcohol freely, was brought into the Philadelphia Hospital suffering from delirium tremens. There was very rapid, tumultuous, and ineffective action of the heart from the toxic effect of alcohol. Dropsy of the feet. No organic heart disease. Digitalis tried, and found unsatisfactory. Caffeine, 2 grs four times daily, promptly effective in augmenting the systole. Within a week its full effect seemed to have been secured. No regulative power was observed, the heart's action continued rapid, and finally became normal when the general balance of the nervous system was restored.

CASE II.—A woman of 65 years. Dilated and fatty heart, with mitral regurgitation, hydrothorax, general anasarca, ascites. Was admitted to hospital August 1st, and in the interval to November 1st was tapped three times; and various diuretics, always accompanied by digitalis, were given. November 1st she was placed on 4 grs. of caffeine in pill three times daily, and within two weeks a veritable transformation had occurred. Dropsy vanished, and the cardiac systole greatly improved. At date, condition still satisfactory. Caffeine discontinued.

CASE III.—Boy of 10 years, with mitral disease, dilated hypertrophy of all the chambers of the heart, influenced by the lesion; ascites. This patient has been under my care for five years. No drug that I have ever used has proved so satisfactory and rapid in its influence as caffeine.

CASE IV.—Emphysema and cardiac dilatation; and under my observation for several years, finally threatened with evils of cardiac failure, and uræmia imminent. Most satisfactory results from the use of caffeine.

CASE V.—Atheroma and aneurism by dilatation. Dilated hypertrophy, with fatty and feeble heart. Digitalis not well borne on account of the pathological changes in the aorta. Jaundice and other evidences of cardiac failure, and venous repletion. Very favorable results from caffeine.

ON SURGICAL TUBERCULOSIS.

BY R. J. HALL, M.D.,
OF NEW YORK.

(Concluded from page 99.)

IV. Miscellaneous Tuberculoses.

CASE I. *Tuberculosis of the Tongue.*—February, 1884. Amputated in 1881. Old alcoholic preparation. Microscopic examination shows diffuse tubercle, containing many giant cells and extensive cheesy degeneration. Five preparations: four negative; in one a giant cell contains three bacilli, and two others contain two each. This case is of interest as confirming the observation made by Vidal, and referred to above, that the bacilli can be found in old preparations. I am inclined to think, however, that many bacilli had undergone some change which interfered with the staining, for the sections examined were very large, and a really enormous number of giant cells had been carefully gone over before these very few bacilli were found; while Koch[87] in two cases of tubercular ulcer of the tongue found large numbers.

CASE II. *Pus drawn with Hypodermic Syringe from Abscess in connection with Tubercular Orchitis.*—Two preparations: fuchsine; one negative; one contained four bacilli.

Case III. *Pus from Cold Abscess of the Right Iliac Fossa.*—Occurring in a young woman, with symptoms pointing to caries of the lumbar vertebræ. Pus allowed to settle and sediment taken. Five specimens: violet and brown; two negative; one contains four, one two, and a third one bacillus.

Case IV. *Pus from Cold Abscess, connected with Tubercular Arthritis of Shoulder.*—Boy, æt. 15, disease of four months' duration. Pus drawn with hypodermic and allowed to settle. Eight specimens: violet and brown; five negative; in one, one bacillus; in each of the remaining, two found. In several of the specimens large spores, exactly resembling those described and figured by Koch,[88] were seen stained violet; the only difference from those mentioned by Koch being that no uncolored spores of the same size were seen. The pus had stood more than twenty-four hours before being spread on cover-glasses. This is the only occasion on which I have seen such spores. They are not, of course, supposed to have anything to do with the tubercular process, and are only of interest because they stain in the same way as the bacilli. What are generally believed to be the spores of the tubercle bacillus are only to be seen as minute unstained interruptions in the stained body of the bacillus. As they cannot be stained in any known way they may, of course, exist in large numbers in tissues or fluids without our being able to appreciate their presence, and this affords a plausible explanation of the fact that material in which few or no bacilli can be found, such as cheesy substances, often possesses most virulent infecting properties. I have examined the sediment of urine in a number of cases of pyelitis, supposed to be tubercular, without finding the bacilli in any of them.

The small number of cases in which I have made examinations of pus, is due to the fact that Schlegtendal[89] had already made extensive observations in this direction. It was obvious almost from the first that the examination of sections for diagnostic purposes could find but a very limited application on account of the time and labor required for preparing and examining them. With pus, however, which can usually be obtained before operation, and is dried on cover-glasses like sputum for examination, the process is a much simpler one, and could the bacilli be found with any certainty, it would be a valuable resource in doubtful cases. In forty cases of tubercular bone, joint, and glandular disease, in which the abscesses had not yet been opened, Schlegtendal[89] obtained positive results in only seventeen. In fifty-five cases of tubercular fistulæ communicating with bones, joints, glands, and the urinary apparatus, with five of tubercular ulcers of the skin, he obtained only nine positive results.

The most, therefore, that we can say, is that in a certain number of cases the discovery of the bacilli may give us certainty, while the failure to find them offers no presumption against the tubercular character of the disease. Something, I think, is gained by letting the pus settle for several hours, and examining the sediment.

Although Friedländer,[90] Rosenstein,[91] M. Babes,[92] and Kredic,[93] have found the bacilli in the sediment of the urine of patients suffering from genito-urinary tuberculoses, my own results lead me to believe that it will prove of little more value here than in fistulæ and ulcerations.

V. Tubercular Epididymitis.

Man, æt. 50. Disease first noticed three months ago, and suppuration had occurred rapidly. Castration, July 22, 1884.

Inoculation of guinea-pig subcutaneously in abdomen with tubercular material. Wound of inoculation closed perfectly. Within two weeks a sluggish ulcer had formed; inguinal glands became rapidly enlarged. Sept. 7, enlarged inguinal gland excised. It is almost entirely caseous and broken down in the centre.

Examination of cheesy matter on cover-glasses shows considerable numbers of bacilli (violet and brown). This case illustrates the ease with which inoculation can be used for diagnostic purposes. The actual operation takes but a few minutes, and the bacilli occur in such numbers in the caseous lymphatic glands that the demonstration is as rapid and simple as in sputum. Only in lupus it seems that, probably on account of the very small number of bacilli, inoculation may frequently give no result. Though even here, as Koch has obtained such uniform results, it is possible that the failures depend on errors in manipulation.

Besides those already mentioned, the most important reports on the discovery of tubercle bacilli in surgical lesions are the following:

Schuchardt and Krause,[94] already referred to, demonstrated the bacilli in ten cases of synovial and three of bone tuberculosis; in the lining membrane of fourteen tubercular abscesses, none being found in the pus which they examined from four of these; in three cases of tubercular glands, three of tubercle of the skin and lupus, one of the sheaths of the tendons, and one of the muscles. In all these the bacilli occurred very sparingly. In a tubercular nodule in the tongue, a tubercular testicle, and two cases of tubercular disease of the female genital organs, on the other hand, the bacilli were very abundant. Bacilli were found in all the tubercular lesions they examined. Demme found bacilli in two cases of ozæna scroph., as well as in the three cases of lupus mentioned before. Chiari[96] found them in pus from carious disease of the vertebræ, and from tubercular cervical lymphomata. Celli and Guarneri,[97] in scrofulous lymphatics; they also made successful inoculations from these, but failed to find any bacilli in three tubercular joints and four cases of lupus. Brouilly[98] found them in an abscess of the epididymis, a fungoid tendo-synovitis, a tubercular abscess of the thorax, and a fungoid osteitis of the rib, very sparingly in all. Wesener,[99] in two tuberculoses of the testicle and epididymis, two of the female genital organs, two of the bladder, and in pus from a tubercular ulcer of the neck. F. Marchand[100] found it difficult to find the bacilli in fungoid joint diseases, and in pus from the same. Debove[101] found them in pus from tubercular epididymitis, a presternal and a costal abscess. W. Müller[102] found the bacilli, as a rule, in thirty to

thirty-five cases of fungoid disease of bones and joints. He found none in a number of cases, even after examining twenty or more preparations, and these were especially such as were undergoing spontaneous cure. In four cases, the bacilli occurred in very large numbers. Coze and Simon[103] have seen them in the granulations of fungoid joint disease, and sometimes in pus from the same; also in the purulent discharge from the uterus of a patient with pulmonary tuberculosis. Kanzler,[104] in four cases of osteomyelitis and osteosynovitis, and fourteen times in pus from thirty-one cases of tubercular disease, including suppurating lymphoma (7,–2 positive), bone and joint disease (13,–8 positive), ulcers of skin (7,–4 positive), of nasal mucous membrane (2, negative), and suppurative otitis media (2, negative). Gondolphe[105] found them in pus from cold abscess in fungoid disease of bone and joints, tubercular epididymitis, and renal tuberculosis. M. Hanat[106] publishes a case of panaritium, either originally tubercular, or, as suggested by a reviewer, possibly infected by the bistoury used to incise it, and followed by a tubercular ulcer of the forearm; in the pus and in sections large numbers of bacilli were found.

Koch,[107] besides the cases already referred to, has examined 13 of joint and 10 of osseous tuberculoses, finding the bacilli in all, and failing to find them only in pus from 1 case, in which, however, inoculation was successful. He found them further, very sparingly, in 5 tubercular testicles; very abundantly, on the other hand, in four cases of tuberculosis of the pelvis of the kidney, 1 of the bladder and urethra, 1 of the suprarenal capsule, and 1 of the uterus and tubes. No bacilli were found in the pus from an abscess of the kidney, but inoculation gave a positive result. Eschle[108] has found abundant bacilli in the discharge from two cases of suppurative otitis media, both patients having pulmonary tuberculosis. Voltolini[109] describes a similar case, the bacilli being also very abundant. The same author[110] also found bacilli in three cases of pharyngeal tuberculosis, all accompanied by tubercular disease of the lungs or larynx, and mentions that he usually finds them in the secretion from laryngeal ulcers. In a later[111] publication he gives in detail an interesting case of a child of five years, in whom the first symptom was the appearance of bilateral cervical lymphomata, followed by hoarseness, and later, aphonia. Only the swollen epiglottis could be seen laryngoscopically, and a certain diagnosis was made only by the discovery of tubercle bacilli in the secretion. B. Fränkel[112] had some time previously announced the regular occurrence of the tubercle bacilli in the secretion from tubercular laryngeal ulcers, having found them in twenty-two cases examined during life, and five after death. During the discussion which followed the reading of Fränkel's paper, Lewin[113] stated that he had succeeded in finding the bacilli in the same way. Some doubt was thrown on the reliability of Fränkel's observations by Friedländer, because in the preparation presented to the Society no tubercle bacilli were to be seen. The preparation, however, was some weeks old and faded, and at the next meeting of the Society, Fränkel was able to make a satisfactory demonstration of a number of preparations. Guttmann[114] has recently reported two cases of tubercular ulcers of the soft palate, in both of which immense numbers of bacilli were found.

In a review of the literature given above, it will be seen that, as a rule, the bacilli are abundant in tubercular lesions of mucous membranes and internal organs, while they are found very sparingly in those of the skin, bones, and joints; a rule, however, not absolutely without exceptions. Two important practical subjects remain to be considered, namely, the means of diagnosis at the command of the surgeon, and the indications for treatment.

For the first, as a rule, the clinical diagnosis is not difficult. All that we have been accustomed to consider scrofulous must be classed as tubercular, with the exception, probably, of those superficial affections of the skin and mucous membranes, which are rather diseases of the scrofulous than scrofulides. No doubt, also, further observation will show the presence of the bacillus in some of these apparent exceptions.[115] But far more than this must be included. Its forms are so various, and its course so dissimilar in different cases, that sometimes before operation only a probable diagnosis can be made, and that largely by exclusion. We must be prepared to recognize tubercular lesions of the bones, the joints, the skin, etc., in both children and adults, who, except for this one affection, present all the appearance of the most blooming health. We must be prepared to find it running an acute course, in a bone or joint, for instance, producing, in a few days or weeks, an amount of disorganization that would ordinarily require months or years, and again existing in the same situation for the greater part of a lifetime, and scarcely causing derangement of function.

Usually the gray, gelatinous, miliary tubercle, either on the surface of a membrane or scattered through the tissues, with here and there white specks, denoting caseous degeneration, can be readily recognized with the naked eye. Not very infrequently, however, cases will occur in which neither clinically nor on microscopical examination a certain diagnosis can be made. The question then arises, Have we any simpler means than the tedious and difficult examination for the usually small number of bacilli? It is quite certain that neither the epithelioid nor the giant cell is characteristic of tubercle.[116] While it may be true, as Ziegler states, that "for the later stages of the tubercle, nodule caseation is characteristic,[117] yet this is not always present, and closely similar degenerations occur as the result of so many pathological processes that it cannot be relied on for the diagnosis.[118] Giving up, then, as has been done in regard to all other pathological processes, the idea of a specific cell form, pathologists have fallen back upon the characteristic structure of the tubercle. This consists, as defined by Ziegler,[119] in "a non-vascular nodule (knötchen), which does not grow beyond a certain size, and, having attained a certain stage of development, undergoes cheesy degeneration." We may add to this, as Ziegler does a little further on, that usually many of the cells are epithelioid, and that the nodules usually contain one or more giant cells. Even this characteristic structure, or something very similar, can be produced by the irritation of various

foreign bodies, if we may rely on the statements of Baumgarten[120] and the experiments of H. Martin, [21] who claim to have produced, by the action of various irritant foreign bodies, a structure histologically identical with true tubercle, and differing from it only in being non-infective.

Be this as it may, however, the fact remains that before the discovery of the tubercle bacillus the whole domain of tubercular lesions had been mapped out entirely by the aid of histological criteria; and that since Koch's discovery the bacillus has not been found except in tissues presenting the characteristic structure, nor, so far as investigations extend at present, has the bacillus been wanting in any form of the disease which had been classed as tubercular on anatomical grounds.

Practically, therefore, the simple microscopic examination of the tissue affords a perfectly reliable and simple means of diagnosis. Where sufficient material cannot be obtained for the purpose, we can only have resource to inoculation, or to the method described by Unna,[122] who found that by partially digesting hardened specimens and examining the precipitate that had fallen, the bacilli were observable in quantity.

As regards treatment, the discovery of the bacillus has taught us, when local recurrence takes place after operation, to seek for the cause, not in any mysterious predisposition of the tissues to tubercular inflammation, but in the failure completely to remove the infecting material. As for any specific action by internal treatment, we are apparently further from success in this direction than ever. Buchner[123] and Kempner[124] have, indeed, reported favorable results from the treatment of pulmonary tuberculosis by arsenic, and Landerer[125] and Von Langenbeck[126] in a small number of cases of fungoid disease. Stintzing,[127] on the other hand, in sixteen cases of phthisis, most carefully observed, found practically no benefit at all. Parrot and Martin[128] found the bacillus more resistant than that of splenic fever. Solutions of corrosive sublimate, salicylic acid, superoxygenated hydrogen, bromine, quinine, and creasote, in the strength of 1 to 1000, were useless. Carbolic acid solution, 3 per cent., was effective only after forty-eight hours, and 6 per cent. failed in twenty-four hours. With these data in view, I am inclined to receive Doutrelepont's[129] report of favorable results in lupus, from the application of 1 to 1000 corrosive sublimate, with great reserve. Koch[130] gives the following result of his and Gaffky's experiments in this direction:

"At different times rabbits received injections of pure cultures (of tubercle bacilli) in the anterior chamber of the eye in order to test the influence of substances which interfere with the development of the tubercle bacillus. Besides numerous other substances, arsenic, helenin, and sulphuretted hydrogen, were administered to the animals, and always in the largest possible doses, and for weeks at a time. We have not been able to observe a favorable action by any substance in a single case. All the animals died tubercular, just as rapidly as those which were not treated." Koenig,[131] moreover, after stating that he has for years past carefully tested the different agents recommended, especially iodine, mercury, and arsenic, and that none of them has shown anything like a specific action, continues: "In no single case have I been able to determine that arsenic had a permanently good or bad influence on the course of the disease, whether situated in the joints, in the skin, or in the kidneys." Invaluable as iodoform still proves as a dressing, especially after operation in tubercular cases, it certainly has not satisfied the expectations excited by Mosetig-Moorhofs[132] and Mikulicz's[133] earlier publications. Although Marchand,[134] by proving that iodoform causes the rapid disappearance of giant cells from the inflammatory products surrounding foreign bodies, has given some anatomical evidence in favor of a possible special action of iodoform on granulations containing these, yet the fact that even those surgeons who use iodoform most extensively, demand at the same time the complete extirpation of all tubercular tissue, does not speak strongly in favor of a specific action.

On the other hand, a more intimate acquaintance with the course of tubercular processes, and especially the observations of Baumgarten,[135] who, in about every third or fourth cadaver, dead from other causes than tuberculosis, finds some vestiges of tubercle, prove that it is by no means always the malignant process that observation of only the more acute cases would lead us to believe, that in fact many cases tend to spontaneous recovery. I am inclined to think myself that, in most cases, the course which the disease will take is settled from the first, either by the nature of the soil, or the amount of the infecting material, and that it is far less influenced by treatment whether general or local, other than operative, than surgeons generally suppose. When the specific character of the disease was first recognized, and the frequency noted with which subjects of fungoid or other local tubercular processes fell victims to acute miliary or pulmonary tuberculosis, it was but natural that surgeons should have advocated early operative interference for the sake of prophylaxis.[136] This ground has been completely cut away by the statistics of Koenig,[137] already mentioned, according to which in 79 per cent. of all cases of tubercular bone and joint diseases examined, older tubercular deposits were found as the probable source of infection. Baumgarten's work, cited above, makes it probable that in a still larger percentage of cases the surgical affection is secondary. The failure of these too sanguine expectations, the small but nevertheless noticeable number of cases in which acute tuberculosis directly follows operative interference,[138] and above all the frequency of local recurrence, added to the often unsatisfactory results as to function after resection of joints, have caused a decided reaction in favor of more expectant treatment. Now, as before, however, we possess but one means of limiting or cutting short the local tubercular processes that is, the complete extirpation of all the diseased tissue, as advocated by German surgeons in general, and especially by Volkmann, in 1879,[139] and recently at Copenhagen;[140] and as improvements in operative technique and wound dressings diminish day by day the dangers, and render results more certain and satisfactory, we will, I am confident, have recourse

more and more frequently to early and radical operation.

† See, also, Orvosi Hetilap, No. 32, 1882, ref. in Centralbl. f. Chir., 1883, No. 51. V. Babes, Tuberkel-bacillen in der Scheide, in der Urethra, in Geschwüren Circa Anum, and der Lippe. The ulcer of the vagina and lip were in the same patient; bacilli abundant in all; and tubercular serous effusions. MM. Chauffard et Gombault (Bull. et Mém. de la Soc. Méd. des Hôpitaux, ref. in Lancet, August 30, 1884) inoculated 23 guinea-pigs with serous, sero-fibrinous, or purulent effusions, of tubercular character, from pleura or peritoneum of 21 patients; inoculations intraperitoneal: 4 guinea-pigs died rapidly; 9 showed no tubercles after 34 months; 10 tubercular, and bacilli in all; no bacilli found in the effusion.

MEDICAL PROGRESS.

CANCER OF THE THYROID BODY.—M. MARCHAND, in the *Gazette Hebdomadaire* of Dec. 26, 1884, reports a case of cancer of the thyroid body, which is interesting on account of its rarity, the peculiarity of its progress, and the symptoms to which it gave rise. The patient was a woman thirty-two years of age, without hereditary taint of any kind. She had always had a large neck. At the time when she first came under the notice of M. Marchand, a tumor of the size of a hen's egg was discovered on the right of the median line. Its appearance was first noticed six months previously. In contrast with the cases heretofore published, in which a rapid progress has been noticed, complicated with disturbances due to the compression of the œsophagus, the tumor was developed slowly, and the respiratory function alone was interfered with. Dyspnœa, at first temporary, finally, at the end of six months, became constant. Accurate examination was impossible, as pressure produced marked stenosis of the trachea.

Treatment with potassium iodide gave only temporary relief. Thyroidectomy was then decided upon in preference to tracheotomy. A longitudinal incision was made extending to the sternal notch. The tumor thus exposed was of a reddish-white color traversed by large vessels, perfectly circumscribed, but enveloped in a dense fibrous tissue, from which it was difficult to isolate the vessels. Ligatures were applied above and below, and the tumor was excised between them. The trachea was found intact. The edges of the wound were united by metallic sutures and the wound rapidly healed, and the woman left the hospital in three weeks.

The tumor was very large, projecting nearly four inches, and having a circumference of nearly ten inches. Microscopical examination showed it to be cancerous. After three months, there are no signs of return, either local or general. Rose, up to 1879, only could collect three cases of thyroidectomy, all followed by death. Billroth has since had three cures—two temporary, of two years' duration, and in a third there has been no return, two years after operation.

CLINICAL OBSERVATIONS UPON DIPHTHERIA.—DR. LUDWIG STUMPH, in an exhaustive clinical study of diphtheria, extending over a period of twelve years, concludes as follows:

Diphtheria of the throat, nose, vagina, conjunctiva, and of the mucous membrane of all the external air-passages, is primarily a purely local disease. This primarily local disease can, in its further progress, lead to a general infection of the body. From the local nature of the disease, it is manifest that local treatment alone, and thus the subjugation of the disease at its primary point of appearance, will perfectly fulfil the present scientific aspects of its nature. By thorough and early local disinfection, for which inhalation offers the best therapeutic means, all that is possible is accomplished.

Against universal infection there is at present no remedy. It is possible that we shall eventually find a substance which, without injury to the blood and the vitality of the tissues, will exert a germicide effect upon the organism in the blood, though at this time there is no prospect of such discovery. The task of the physician is to pay attention to the primary local disease, and to concentrate the treatment upon this, and this must be the principal aim of his labor.—*Deutsches Archiv für klin. Medicin*, Dec. 1884.

TREATMENT OF CHOLERA.—As the result of extended observations upon Asiatic cholera, made during the recent epidemic, DR. OSCAR GIACCHI gives, in the *Gazzetta Medica di Torino*, of Dec. 24, 1884, the following conclusions as to the best treatment of the disease:

1. In true Asiatic cholera, when once an algid condition or a state of asphyxia is present, medication is useless; or, at least, is no more to be relied upon than are the simple natural powers.

2. Medication in the first stages of the disease, when the infection has not yet poisoned the blood and prostrated the nervous system, is often effective.

3. Laudanum is the remedy *par excellence* in the disease, perhaps the only one which will control the intestinal watery discharges due to intestinal hypersecretion.

4. Stimulants generally, and alcohol in particular, are valuable as a means of support till reaction has set in.

5. Notwithstanding the doubtful results of treatment of the disease in the advanced stages, all symptoms should be met as they arise.

6. A symptom most important to recognize, is the algid state which precedes central paralysis. In this condition, the hot bath must be resorted to, and renewed as often as required; likewise stimulants, alcoholic and non-alcoholic, and artificial heat should be used.

7. After the advent of the algid stage, vomiting usually follows, which further prostrates the powers of the patient; and by preventing the retention of medicines in the stomach, diminishes the chances of recovery. The best remedy for this condition is chloroform, in doses of from twenty to thirty drops in some stimulating vehicle, or mixed in effervescing lemonade.

8. Cholera which has completely developed cannot be directly cured by any means, and should not be treated by theoretical specifics.

9. Prophylactic measures, during the presence of an epidemic, to prevent the spread of the disease, are better than medical treatment, however skilfully directed.

CANCER OF THE EYE.—An important study of cancer of the eye has just been completed by M. GUSTAVE DRON. The work contains an extended observation upon a case of sarcoma of the choroid, reported to the author by M. Alp. Desmarres; a study of cancer of the globe; and finally, a general discussion upon the nature of the different varieties of cancer and their etiology. The case of choroidal sarcoma was diagnosticated at its first appearance, operated upon, and at the end of five years has not returned. Showing clearly the symptomatology of cancerous growths, and the mode of distinguishing them, M. Dron insists especially upon the radical treatment of the disease, which consists in the complete extirpation of the eye and all its appendages, if the growth has at all invaded them. Considering the subject from a practical standpoint, he regards histological distinction as of only minor importance.—*Gazette Medicale de Paris*, Dec. 27, 1884.

The Combined Action of Antipyrin and Kairin.—In a memoir upon the combined action of antipyrin and kairin, Dr. G. Mingazzini publishes some extended observations. The diseases in which the effect of the drugs was noted are phthisis, catarrhal pneumonia, typhoid fever, and croupous pneumonia. In each case satisfactory effects were obtained. The doses employed varied from 8 to 30 or 40 grains of each drug. As the result of his experience, Dr. Mingazzini offers the following conclusions:

1. The ingestion of a mixed dose of antipyrin and kairin produces a much greater reduction of temperature than if an equal quantity of antipyrin alone is administered.

2. The ingestion of a mixed dose of these two drugs usually results in an immediate reduction of temperature, which continues much longer, *cæteris paribus*, than when antipyrin alone is administered.

3. Kairin, administered with antipyrin, does not produce any of the untoward effects which are observed when it is administered alone.—*Gazetta degli Ospitali*, Dec. 1884.

The Thermo-cautery in the Treatment of Spontaneous Gangrene.—Dr. Dessette publishes in the *Journal de Méd. de Paris*, Jan. 3, 1885, a case of gangrene of the left foot, incident to diabetes mellitus, which was successfully treated with the thermo-cautery. The case is of interest from two points of view:

1. It shows the influence of alcohol in producing gangrene in diabetics. Gangrene of the extremities is not frequent in diabetics—one case in fifty being unusual—and, what is remarkable, the case exists in connection with alcoholism, having required, as it seems, a double diathesis—the alcoholo-diabetic, to cause the gangrene.

2. It presents an instance of cure without recourse to the bistoury. The diseased parts must be thoroughly cauterized as the gangrene progresses; and, though the patient may thus lose one or more toes, or the foot itself, he is finally cured.

Hydrocele in the Female.—Hennig, of Leipzig, read a paper on this subject before the Society of German Naturalists and Physicians, in Magdeburg.

Hydrocele in the female, he said, is very rare; he has been able to find only thirty-nine cases recorded in literature, and has had two cases in his own practice. Apart from their interest to the gynecologist, these cases merit the attention of accoucheurs, as hydrocele may render delivery very difficult, or even impossible; furthermore, the exudation, by passing up the inguinal canal into the abdomen, during labor, may cause peritonitis; three instances of this accident are recorded. It may also cause sterility; a case is reported in which sterility of fourteen years' standing was cured by removal of the hydrocele. Zuckerkandl made post-mortem examinations of the bodies of nineteen young girls, the ages ranging from one to twelve years; in four cases he found the so-called Nuck's diverticulum, bilateral in three cases. If the hydrocele communicates with the abdominal cavity, the contents may be forced out into the cavity. In many cases small sacs are found in the course of the round ligaments; they are liable to occur after traumatism, and to become inflamed.

Hydrocele occurs from the seventh to the seventieth year, and is more frequent in women who have borne children than in nulliparæ. In 8 cases it was on the right side, in 6 on the left, in 2 it was bilateral. Of 40 cases, the hydrocele completely filled the canal in 25; of these, 3 did not communicate with the abdominal cavity, and 15 were closed cysts. In 5 cases the fluid was bloody.

The affection begins painlessly. At first the swelling is slight, and disappears on lying down. Though there is seldom any fever at first, it comes on when the hydrocele becomes inflamed, which may occur from excessive tension. Erysipelas has also been observed before an operation. Hydrocele in the female has been mistaken for hernia; the diagnosis can be easily made in some cases by the use of the aspirator needle. The hydrocele has been known to suppurate in a few cases, but the suppuration has never extended to the abdomen. Of 28 cases of hydrocele, 23 were cured, and the hydrocele returned in 5 cases. The treatment consists at first in placing a bandage over the sac, and later in making an incision and filling the sac with charpie.—*Centralbl. für Gynäk.*, Oct. 11, 1884.

Treatment of Rachitis by Phosphorus.—Dr. Schwechten, at a late meeting of the Berlin Medical Society, communicated his observation upon the treatment of rachitis by phosphorus.

According to Kassowitz, rachitis is the result of an inflammation of the bones and of the production of an osteoid substance deprived of the calcareous salts. He has produced in animals, by giving them continuously large doses of phosphorus, symptoms very analogous to those of rachitis, and has noticed that very small doses diminish the vascularity of newly formed osseous tissues and their tendency to rachitis, whence originated the treatment he so highly praises and which has given such brilliant results. M. Schwechten has not confirmed these results by his own experiments. He administered the phosphorus in an oily solution in doses of $\frac{1}{128}$ of a grain daily, as directed by M. Kassowitz. Forty-one patients were treated by this method: four were cured, twelve were decidedly benefited, nine moderately improved, eleven experienced no change, five grew worse, and eight died, giving a total of twenty-five successes and sixteen failures. Dr. Schwechten, therefore, does not consider phosphorus a specific for rachitis, and holds that the drug is only directed to one set of symptoms of the disease. Notwithstanding the contrary opinion of Kassowitz, he considers rachitis a general disease affecting other than bony tissues. Dr. Schwechten holds the view that improper hygienic conditions frequently cause the development of rachitis, and that the disease may be ameliorated and even cured by the simple substitution of good for bad hygienic surroundings.—*L'Abeille Médicale*, Jan. 5, 1885.

An Extraordinary Case of Labor; Putrefaction of the Fœtus.—Dr. R. de Saint-Moulin, in the *Journal d'Accouchements de Liège*, Nov. 30, 1884, reports a remarkable accouchement. The patient was a primipara in labor at term. The belly was enormous, swollen excessively, and tympanitic over its entire surface. Palpation gave no information, owing to the ex-

cessive distention. Auscultation also gave negative results. By touch, the head of the child was felt, filling up the neck of the uterus, like an enormous thrombus. Labor had been in progress four hours, but the woman did not know when the bag of waters had ruptured. Her condition was very grave; respiration difficult and superficial; pulse small and thready; face wrinkled; painful and continued oppression in the abdomen. The forceps were applied and the head, very far advanced in putrefaction, was delivered. Efforts to deliver the remaining parts were in vain.

Saint-Moulin then attempted to deliver the shoulders with the hook, and in so doing both arms of the fœtus were torn off, as also the head, and the same accident happened when an attempt was made to deliver the lower limbs. To deliver the trunk, it was necessary to perforate the abdomen of the fœtus to permit the escape of the gas there collected. The after-birth was delivered immediately, and the woman died shortly after.—*Archives de Tocologie*, Jan. 1885.

Treatment of Pruritus Vulvæ and Ani.—Dr. Atthill, of Dublin, treats this troublesome complaint with carbolic acid. The formula which he recommends is the following:

Acid carbol.,	20 gr.
Tr. opii,	f℥ss.
Acid hydrocyan. dil.,	f℥ij.
Glycerinæ,	f℥ss.
Aq.,	q. s. ad f℥iv.

A tampon of lint soaked in this solution is introduced into the rectum and renewed after each stool.—*L'Union Méd. de Canada*, Jan. 1885.

Infectious Pneumonia.—M. Germain See, in a paper lately presented to the French Academy of Sciences, after reviewing the experiments of Friedlander and Talmon, in which micrococci, from pneumonic exudations, produced pneumonia in the lungs of rabbits and mice, in nowise different from the disease as manifested in man, avows his belief that pneumonia is a specific parasitic disease. A *résumé* of the paper touches the following points: Pneumonia may be reproduced in animals, but reproduction is impossible with ordinary agents, either physical or chemical. In order that the characteristic inflammation may be developed, it is necessary that a special microphyte be brought into contact with the pulmonary tissue, and be there developed. The inflammation remains local if it does not exceed the limits of the pulmonary apparatus; this is simple pneumonia. The disease extends and becomes general when the microbe reaches the circulation, either through the lymphatics or by the blood.

Distinction between such cases of pneumonia and broncho-pneumonia. Parasitic pneumonia (pneumonia by infection) should be absolutely distinguishable from other forms of acute pulmonary inflammation which are described under the name of broncho-pneumonias. In these latter microbes also exist, but the part they play is but secondary. The progress of the disease, as well as its extent, is here dependent upon a preceding bronchitis, having its origin in cold, and upon the extension of such inflammation to the bronchioles and alveoli. Broncho-pneumonia caused by cold is rarely seen elsewhere than in children and the aged, and is very rare in the adult, who is much more the subject of parasitic pneumonia.

In parasitic pneumonia the mode of development is similar to that of the eruptive fevers. As in variola-measles, its duration is limited, and does not ordinarily exceed six or nine days.

Considered from this point of view, he admits but three indications for treatment:

1. To combat the fever by the aid of sulphate of quinine.

2. To sustain the forces of the patient by means of alcohol.

3. To combat inanition by means of nutritious beverages.—*Revue de Thérapeutique*, Jan. 1, 1885.

Hippurate of Lime as a Food.—Dr. Poulet, in the *Journal de Médecine de Paris*, recommends, in numerous affections, the hippurate of lime, prepared as follows:

Hippuric acid,,	3 ounces.
Milk of lime, filtered,	2 quarts.
Warm water,	2 "
Sugar,	5 pounds.
Alcoholic extract of citron,	½ ounce.

The hippuric acid and the milk of lime are mixed by degrees in a portion of the warm water, and tested from time to time until all acidity has disappeared, which requires at least four hours. The remainder of the water and the sugar are then added and boiled till a suitable consistency is obtained. The dose is a tablespoonful two or three times a day. The preparation must be shaken before administration. According to Dr. Poulet, the hippurate of lime as above obtained is specially useful in: 1. Affections of the urinary passages; 2. In diseases of the liver; 3. In certain diseases of the skin dependent on hepatic lymphatic derangement; 4. In numerous diseases of the digestive tract.

The Cola Berry.—M. Beaumetz presented recently to the Société de Thérapeutique specimens of the cola berry, and of the different pharmaceutical preparations of which it forms the basis. The cola berry is the product of the *Sterculia acuminata*, a plant originally from Africa; it is considered by the natives to be a tonic and an aphrodisiac. It contains a great proportion of caffeine, and small quantities of theobromine and tannin. It is employed in the Soudan in two forms: as a masticatory or as an infusion, after being roasted and pulverized. M. Dujardin-Beaumetz has experimented with it in chronic diarrhœa, and has obtained excellent results, analogous to those which the physicians of the navy have obtained from cochinchine. In cardiac diseases, at periods of asystole, the preparations of cola appear to act as coffee and caffeine, at once as a heart tonic and as a diuretic; and finally the general stimulant and tonic effects of the drug may be used advantageously in a great variety of adynamic conditions.

M. Dujardin-Beaumetz used the infusion of the roasted cola berry in doses of about four drachms to a cup of water; of the elixir, or tincture of the cola, in doses of a dessert or tablespoonful. There are also prepared a wine and an alcoholic extract of the cola.—*Journal de Méd. de Paris*, Jan. 3, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, JANUARY 31, 1885.

IS COMPLETE LARYNGECTOMY A JUSTIFIABLE OPERATION?

DURING the past year, in addition to scattered reports of individual cases, several important statistical contributions were made to the subject of complete excision of the larynx, of which the most notable are those of ZESAS, published in the *Archiv für Klinische Chirurgie*, Bd. xxx, Heft 3, and of SOLIS COHEN, in his excellent article on "Injuries and Diseases of the Air-passages," contained in the fifth volume of the *International Encyclopædia of Surgery*. From these and other sources of information, we find that the entire larynx has been removed at least 88 times, a number which is, perhaps, sufficient for the settlement of the vexed questions of the justifiability of the operation and its proper position as a surgical procedure.

The bare results of the 88 cases show that 52 recovered, and 36, or 40.90 per cent., died. Of the 52 recoveries 20 died subsequently of recurrence of the disease for which the operation was resorted to, 12 perished from other affections or accidents, 2 were living with recurrence, and 18 were alive and well for periods which varied from a few weeks to ten years.

If the propriety and advisability of complete laryngectomy were based upon the above record, it would certainly be excluded from the category of established operations by not a few surgeons. Hence, in conducting an inquiry of this kind, impartial justice can only be secured by dividing the cases into three distinct groups, in accordance with the causes for which the procedure was instituted. For this reason we will discuss the operation as performed, first, for carcinoma, secondly, for sarcoma, and thirdly, for other affections.

1. The cases of carcinoma number 76. Of these 43 recovered, and 33, or 43.42 per cent., perished, the cause of death having been pneumonia in 19, bronchitis in 1, pulmonary emphysema in 1, collapse in 5, exhaustion in 3, hemorrhage in 1, the passage of a feeding-tube into the mediastinum in 1, and not ascertained in 2. Of the 43 recoveries, 18 died subsequently from recurrence of the disease, at periods varying from two to thirty months, or at eight months on an average; 8 perished subsequently from other causes or accidents, at periods varying from three to twenty-four months, or at eight months and a half on an average; 2 were living with recurrence respectively at the expiration of twelve and sixteen months; and 15 were alive and well at the dates of the last reports. Of the 15 still living, without recurrence, seven weeks had elapsed since the operation in 1, three months in 2, four months in 1, six months in 1, seven months in 1, sixteen months in 1, twenty months in 1, twenty-one months in 1, twenty-six months in 1, twenty-seven months in 1, three years and four months in 1, and three years and seven months in 1, the date being uncertain in 2. The average life of these cases was sixteen months and two-thirds, while that of all cases, living or dead, after the operation, was six months and a half.

From the foregoing facts, it appears that the immediate mortality of the operation is 43.4 per cent., that the disease recurs in 46.5 per cent. of the recoveries, and that of the living and well cases, the mean duration of life is less than seventeen months. The high mortality of the procedure, especially from lung complications, the large rate of recurrences when life is spared, and the failure in all cases, save two, to bridge over three years—the generally accepted criterion of success in operating for carcinoma in other organs—all go to show that, with our limited experience up to the present time, total laryngectomy for carcinoma is not justifiable, and that the views of Cohen, expressed in a paper published in the *Transactions of the College of Physicians of Philadelphia*, for 1883, namely, that the operation does not tend to the prolongation of life, and that palliative tracheotomy secures the greatest good to the greatest number of those suffering from this disease, are correct.

Although, in the light of our present knowledge, the operation is not advisable, it does not follow that better results will not be obtained in the future. Many of the cases occurred in aged and exhausted subjects, and more were totally unfitted for the operation through the extrinsic seat of the disease and through its extension to the associated lymphatic glands, the tongue, the pharynx, the œsophagus, and the thyroid body.

In his admirable brochure on Malignant Disease of the Larynx, Mr. Butlin echoes the views of those who have studied the life-history of carcinoma when he says, "I think that the experiment has not yet been conducted with sufficient care. The cases have not been selected with special reference to the origin and probable course of the disease. Until this has been done, and the precaution recommended by Landerer has been adopted, I am not prepared to abandon the operation as hopeless. I would, therefore, suggest that in the immediate future, extirpation of the larynx for carcinoma should be practised only for intrinsic carcinoma which is still limited to the larynx, and that tracheotomy should be performed at least a fortnight or three weeks before the extirpation, in order to give the patient a good opportunity of gaining strength to bear the larger operation."

Mr. Butlin has shown that intrinsic carcinoma is much more frequent than extrinsic carcinoma, which is limited to the structures above the false vocal cords, and that it is far less liable to produce lymphatic disease, and to extend beyond the larynx. Hence, intrinsic carcinoma is particularly well fitted for the operation, and that it does influence the result is clearly shown by an analysis of the cases in which the origin of the disease could be traced. Thus, we find that of the fifteen still living without recurrence, the average duration of life is nineteen months and a half for intrinsic carcinoma, as against eleven months and a half for extrinsic carcinoma, and that of those which died of recurrence, the average life was nine months and two-fifths for intrinsic disease, as against six months and one-seventh for extrinsic disease.

As the natural outcome of these considerations, we think that we are fully justified in recommending total excision for intrinsic carcinoma of the whole larynx, after a preliminary tracheotomy, in subjects not too far advanced in years. Under these circumstances, and with the exercise of great care to prevent lung complications, there is no reason why the future mortality should not be greatly reduced, and the number of permanent cures be materially increased. When, however, the disease is unilateral there would seem to be no necessity of removing the entire larynx, as extirpation of one-half of the organ has afforded far better results. Thus, of 7 unilateral laryngectomies, in which the results are known, 2, or 28.57 per cent., died, the disease recurred in six months in 1, and 4 were living and well for periods varying from nine months to three years and a half, or for twenty-one months on an average. Hence, we agree with Hahn, Schede, and Kuester, whose views are expressed in the *Beilage zum Centralblatt für Chirurgie*, No. 23, 1884, in advising the lesser operation for unilateral disease, for the reasons that it is attended with a greatly reduced mortality, and followed by fewer recurrences and a larger number of permanent successes.

2. The entire larynx has been extirpated for sarcoma 6 times, with 5 recoveries and 1 death, the latter having been due to hemorrhage on the fifth day. Of the survivors, Bottini's and Caselli's patients were living and well at the expiration, respectively, of ten and four years; that of Foulis died of phthisis at the end of seventeen months and a half, without recurrence of the disease; Lange's patient perished in seven months from asthenia, with a small recurrent nodule; while the case of Czerny was marked by recurrence in four months, and death eleven months later.

When it is remembered that the patient of Lange was seventy-four years of age, the mortality, which reached only 16.66 per cent., must be regarded as being remarkably slight. In only two cases, or in 40 per cent., was there recurrence, while two other patients were restored to usefulness. These results are brilliant when compared with total laryngectomy for carcinoma, and they are as favorable as are the results of operations for sarcoma in other organs or tissues of the body. The operations of Bottini and Foulis were for intrinsic disease. Of unilateral extirpation of the larynx for sarcoma little can be said, as the only cases thus far recorded are one by Gerster, which recovered, but died of pleurisy, without recurrence, one year subsequently; and one by Kuester, which also recovered, but in which there is no further history.

3. Total laryngectomy for other affections than infiltrating tumors has been resorted to in 6 cases. The operation was done in 1 for syphilitic stenosis, with death from pneumonia in three weeks; in 1 for necrosis and perichondritis, with death from exhaustion on the fifth day; in 1 for tubercle, which recovered, but perished from general phthisis in two months; in 1 for lupus, which recovered, but died of phthisis at the expiration of three years; and in 2 for papilloma, of which one was living two years subsequently, and one recovered, and died of phthisis in five months and a half. Hence, this group of cases indicates a mortality of 33.33 per cent.

From the data contained in the foregoing paragraphs, we believe that we are warranted in concluding that complete laryngectomy is indicated for sarcoma; that it is justifiable in carcinoma when the disease is intrinsic, or has not invaded the surrounding tissues and glands, and when the patients are not too far advanced in years; and that it may be resorted to for other conditions, such as intractable thickening and stenosis, and papilloma which shows a disposition to recur and extend after the employment of less harsh operative procedures.

THE OBSTETRIC PELVIS AND ITS AXES.

THE inclined planes of the pelvic cavity were, under the influence of Baudelocque's teaching, and that of his disciples, so firmly established in the professional mind, as explaining certain movements of the head of the fœtus in labor, that almost every one believed them essential for understanding the mechanism of labor. But even in the country of Baudelocque, these planes are almost forgotten; and few, if any, obstetric teachers now refer to them unless in memory of an effete theory. That great teacher, the late Prof. Hodge, held faithfully to these inclined planes, only deviating from the teaching of the great French master by placing the arbitrary division between anterior and posterior planes somewhat further back. But even this change has not saved the inclined planes.

At one time, in studying the axis of the pelvis, all authorities were agreed upon the curve of Carus as being that axis; this curve was as settled a line in arbitrary obstetric anatomy as Mason and Dixon's line was in the political history of our country—each was an assumed finality. The progress of events has taken away all significance from the latter line, while a supposed more accurate study of the pelvis has led to the abandonment of the Carian curve. In place of this curve we were given by obstetricians, who still held to a mere obstetric study of bones, the curve of the parabola; that was declared to be the axis of the true pelvis. One retains such pleasant memories associated with his study of the parabola, in college days, that it was delightful to find that this curve was a part of obstetric study; then, too, the movements of the fœtus through the birth canal seemed so clear when the student was taught that this canal had a parabolic form. Metabolism in physiology, parabolism in obstetrics!

But, alas! the parabola is threatened; it is probably doomed to follow the curve of Carus and the inclined planes to the tomb of the Capulets. DR. ALPHONSE BOISSARD has recently published a very interesting monograph, *De la Forme de L'Excavation Pelvienne considérée au point de vue obstétrical*, in which he states that different obstetric writers have until recent years been more preoccupied in giving an exact description of either a dry pelvis under their eyes, or of a pelvis ideally conceived in their mind, than in representing the pelvis as it actually is, comprising not only bones, but soft parts. He holds that as to the pelvis in its fresh state, the coccyx really occupies the fundus of the cavity, and the line measuring the depth of this cavity is the central line or axis, which thus obviously is a straight line. This is the line in which the fœtus descends, and then presses upon the part of the basin formed at the expense of the pelvic floor. According to him, the pelvis does not in any respect present the aspect of a curved canal, but rather of a cavity largely cylindrical, presenting two walls, anterior and posterior, almost vertical, and a fundus forming a plane nearly perpendicular to these walls. He states that Fabbri has proved this configuration of the pelvis by pouring into the entire pelvis—that is, the bony pelvis along with the membranous canal formed by the soft parts—liquid plaster, and the cast thus formed shows the shape of the entire pelvis.

As the opening by which the fœtus is to escape is upon the plane of the anterior wall, it must, after descending to the bottom of the excavation in a straight line, entirely change its direction in order to pass through the membranous canal: the axis of this canal is at a right angle with the axis of descent. We have thus as representing the axis of the birth canal not a curved line, but two straight lines, the one nearly perpendicular to the other.

The views of Dr. Boissard are more than interesting—they will prove useful, and if accepted, as we believe they will be finally, will make it easier to understand the mechanism of labor, and they will also prove of use in practical obstetrics.

THE SEMIRAMIDIAN OPERATION.

THE association of the name of the inventor of a new instrument, or the modifier of an old one, or the originator of an important operation, is quite just. How grandly a man grows in professional estimation if he has invented a speculum, or a pessary, or modified surgical or obstetric forceps! Modest, as he may be by nature, how is his vanity fed by the catalogues of instrument makers and the display in their windows and cases!

But still greater is the fame of those who first advise or do important operations. These operations are generally known by their names, and, even when their diffidence may prevent themselves laying claim to such honor, the love of hero-worship, which, according to Carlyle, is so strong in the human heart, and the sense of justice, which is so decided in the medical mind, make others eager to do honor and justice to these inventors, and they are ready to declare, in the face of the whole world, "We will call it Brown's, or Black's, Green's, or White's operation," as the case may be.

Confident in this admiration on the part of the medical mind for whatever is honest and just, we wish to rescue from oblivion in this regard the name of the one who was first to extirpate the human testicles. In thus doing, we are glad, too, it will be shown that, ages before our distinguished countryman, Dr. Battey, performed the operation which he called normal ovariotomy, but to which a just and grateful professional world have with one voice given

his name, one of the most famous queens of antiquity performed normal orchidectomy.

The removal of the testicles—the *little witnesses* not having which a man could not testify in a Roman court—has been done for various reasons. Thus, for awhile charlatans in France, travelling through the country, extirpated these organs to prevent hernia; and it was not until 1776 that this practice was stopped by law. The testicles have been removed in order to secure sopranos for the church and keepers for seraglios, and in Egypt such removal was the punishment for rape. Some celebrated characters in church or State have removed their own testicles in order to save themselves from temptation or from slander. Apart, too, from orchidectomy for disease of the organs, the operation has been done with the hope of curing epilepsy, and who knows but in the future it may have as ample a field in the cure of this and some other neuroses as is now assigned to removal of the ovaries! So much the more reason that she who originated the operation should be properly honored for not only showing what a woman could do, but also for demonstrating the safety of the doing.

Unfortunately, we have no authority earlier than one of the Latin poets to quote in favor of the operation being first done by Semiramis, for it is to this illustrious queen the honor belongs. Nevertheless, the statement made by this poet is unequivocal:

Semiramis teneros mares castravit omnium prima.

Those thus castrated were made overseers and guardians, the operation rendering them more tractable and obedient.

As Semiramis lived in the thirteenth century before the Christian era, an earlier claimant for priority in this operation is not likely to be found, and, therefore, we think it ought to receive her name, and be known to the latest ages as the Semiramidian operation.

A serious objection to the operation, unless when done on account of grave disease, is that, from a physiological standpoint, a man's testicles are not his own—they were made not for him, but for posterity. Nevertheless, moral considerations, the improvement of society, and the development of the race may possibly sometimes conflict with such physiological law.

THE SPREAD OF PROPHYLAXIS AGAINST TUBERCULOSIS.

Notwithstanding the fact that the new doctrine as to the bacillary origin of tuberculosis met with more direct opposition in Austria than in any other country on the continent of Europe, the Austrian Government now recognizes its infectious nature, and has directed its hospital authorities to isolate completely all patients suffering from phthisis, and to take into consideration the employment of such other prophylactic measures in harmony with this view as may be necessary to prevent the extension of the disease.

Abundant opportunity for testing the value of such precautionary measures likewise exists in the large municipal hospitals of this country, such as the Charity Hospital in New York, and the Philadelphia Hospital in this city, in which fully one-half of the cases treated are of phthisis, and we commend a trial of them to the physicians of these institutions.

In this connection we may say we have reached a stage in which it would seem right that hospital authorities generally should insist that their surgeons adopt antiseptic principles in their hospital practice.

REVIEWS.

A Practical Treatise on Fractures and Dislocations. By Frank Hastings Hamilton, M.D., LL.D. Seventh American Edition. 8vo. pp. xxxi., 1005. Philadelphia: Henry C. Lea's Son & Co., 1884.

To praise a work which has reached a seventh edition is superfluous. It stands by itself, and has a character which cannot be much affected by any words of a reviewer. Some books, of course, have a more or less successful career for which it is impossible to account upon any discernible literary principles; but when the work is a professional one, appealing to the practical wants of busy men, its longevity is traceable to its excellence. Dr. Hamilton's book took upon its first appearance, and has since maintained, a very high position as a classical and authoritative monograph. In its successive editions care has been exercised to keep it abreast of a rapidly progressive science, and in this latest issue there is manifested much painstaking and conscientious effort to include within its covers all recent and valuable additions made to the subject of which it treats.

When medical journals teem with figures and descriptions of apparatus devised by different surgeons to meet their individual opinions, or to suit particular cases, it is not to be expected that all will find place in any single volume, however comprehensive its scope. Nor is it desirable that a work so generally referred to as that of Prof. Hamilton's should be so encumbered. It is enough that the underlying principles of treatment should be clearly enunciated, and a limited number of the infinitely varied forms of dressing given. Certainly no one can complain that the book is wanting in either of these respects, and the tyro in our art will often be bewildered when he turns over its pages in the attempt to decide what form of apparatus he will adopt in any given case as he familiarizes himself with the many varieties detailed by Dr. Hamilton. But if he will carefully consider the anatomical principles laid down by the author of the volume, and accept his judgment concerning the merits of the various dressings, he will not greatly err. In the matter of expressing his own opinions, however, we think Dr. Hamilton too often

errs on the side of modesty. Modesty is a very good thing, as is the case with most scarce articles, but many students would be glad to have opinions of a more ex-cathedra tone from one whose experience and learning well entitle him to pronounce such utterances. We well remember the oft-repeated expression of a distinguished professor in the University of Pennsylvania, who, when trea by some learned student to various theories and plans of treatment, would reply, "But what do I teach, sir?" and the definite teachings of that *I* impressed themselves upon his pupils, supplying a sound and firm basis to which they may have added much since, but from which they are not readily moved. Dr. Ham ton's principles are sound, and his opinions are entitled to more than respectful consideration, while the very thorough way in which he has noticed the accumulated observations and experience of other surgeons, shows that he is far removed from anything like unreasonable self-sufficiency.

The references to recent works are very numerous, while no less than three hundred and seventy-five wood-cuts are interspersed through the pages of the volume. As we have said, commendations of the work are not needed. All young surgeons should secure it as an indispensable book of reference, while older ones will regret that there is no way yet devised by which they can exchange their older and time-honored copies for the new edition.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, January 13, 1885.

THOMAS M. MARKOE, M.D., IN THE CHAIR.

DR. CHARLES K. BRIDDON read a paper entitled

SURGICAL OBSERVATIONS IN THE TREATMENT OF THE DISEASES AND ACCIDENTS OF THE LIVER.

(See page 115.)

DR. A. C. POST said that he once had a patient at the New York Hospital who was under treatment for lupus, to which he applied Dupuytren's powder, consisting of one part of arsenious acid and one hundred parts of calomel. After this powder had been applied for some time, the patient was taken with high fever, vomiting, epigastric pain, and jaundice, and he thought that perhaps it was a case of poisoning by arsenic. At all events, the result was fatal; but at the autopsy, Dr. Post was relieved with regard to his suspicion concerning arsenical poisoning by finding that death had been caused by a very large gall-stone obstructing the common duct.

A number of years afterwards Dr. Post was called to visit Prof. Granville Sharp Patterson, whose condition was so much like that of the patient whose history he had just related that he diagnosticated obstruction from a gall-stone, and it proved to be so.

DR. PETERS said that he made the post-mortem examination in the first case reported by Dr. Post..

DR. POST further remarked that there was intense jaundice in both cases, extreme irritability of the stomach, and obstinate vomiting, but death did not occur from coma, as with bile-poisoning.

He had at one time under his care a gentleman who was attacked with febrile symptoms, accompanied by acute pain in the right hypochondrium. At first he suspected pleurisy, but there was no evidence of this affection on physical examination. The patient continued to suffer from the localized pain, but gradually improved, so that he was able to get to Long Island, and Dr. Post lost sight of him temporarily. The acute febrile symptoms had in a measure subsided. During the patient's absence in the country there was a sudden aggravation of the symptoms, and a neighboring physician was called in, who found the man suffering from pneumonia, and was also very much disposed to question Dr. Post's diagnosis with regard to the early history of the case. The attack of pneumonia was a severe one, and was complicated with copious expectoration of dark chocolate-colored fluid. Dr. Post saw the patient subsequently, and found a collection of fluid in the chest, and drew off a considerable quantity of very viscid, chocolate-colored pus. A short time before the patient's death, there was a copious discharge from the bowels of the same material. It was evident that the case was one of hepatic abscess, which had opened into the cavity of the pleura, and had also communicated with the bronchial tubes, and afterwards had probably opened into the colon.

DR. GEORGE A. PETERS referred to a case under his observation some years ago, in which the patient had an attack of trouble apparently in the liver, and finally there was expectorated the contents of a large hepatic abscess, which had opened into a bronchial tube. The patient made a complete recovery. Broken-down liver tissue was found in the material discharged from the first. Subsequently the patient expectorated bile and pus for several weeks, but ultimately recovered, lived for several years, and died of another disease, the original abscess having healed.

Dr. Post saw a lady many years ago who was subject to attacks of acute pain in the epigastric region and right hypochondrium, attended with jaundice lasting for a few days, and which were relieved by the use of opiates and other remedies. These attacks appeared at irregular intervals. On one occasion the patient was seen by the late Richard K. Hoffman, who bled her freely with immediate relief, and she never had a return of these attacks, although she had previously suffered from them repeatedly.

DR. MARKOE said that Dr. Post's case reminded him of one in which the patient, about twenty years before his death, had suffered from what seemed to be inflammation of the liver, and for many days his life was despaired of. The late Dr. Francis saw the patient with him in consultation, and finally suggested that it would be well to bleed, to which suggestion Dr. Markoe acceded, and Dr. Francis bled the patient largely, which gave great relief. Nevertheless the symptoms progressed, and again the patient seemed to be *in extremis* from dyspnœa, and there was a great prominence of the entire hypochondriac region, which was exceedingly tense, but there was no fluctuation. After about two weeks, expectoration of an immense quantity of pus took place, and coincident with this all the symptoms abated. The diagnosis of hepatic abscess seemed to be confirmed by this fact, and that the abscess had discharged through the bronchial tubes. Dr. Markoe's impression at first was

that it was a post-hepatic abscess which had found its way through the lung. After several months the patient recovered substantially, although the expectoration would nearly cease and then return somewhat, and after nearly a year he at times expectorated bile, and subsequently for several years the patient expectorated bile at intervals, which indicated that it was originally an abscess of the liver that had opened into the bronchial tubes, and that a fistula remained. The pus first expectorated was of ordinary color.

DR. MARKOE asked for the experience of the members with reference to the appearance of gall-stones in the passages from the bowels after symptoms of obstruction had existed and suddenly disappeared.

DR. BRIDDON said that he had often searched for gall-stones under these circumstances, but had never been able to find them.

DR. MARKOE said that he asked the question because he saw, many years ago, a lady, sixty years of age, who had been subject to attacks which had been diagnosticated as of this character, and undoubtedly the diagnosis was correct. These attacks were very severe, indeed, and extended over a history of several years. After one of the most severe attacks, she passed a gall-stone, as large as the last joint of his thumb, and from that time the symptoms ceased, and she never had another attack.

DR. KEYES referred to a case, that of a young woman living out of town, whom he had attended during a few weeks while she was in the midst of a number of attacks of the most intense jaundice. The fresh onsets of jaundice repeated themselves for two or three years, and on one of these occasions she was covered with ecthymatous pustules due to scratching, suffered from vomiting, emaciated very much, and her distress was so continuous that she lived chiefly upon morphine and chloroform. The patient said to him that gall-stones had been found in the discharges from the bowels on several occasions. About one month ago Dr. Keyes saw the patient, while again accidentally in the city, when she told him that she was finally cured by taking large doses of phosphate of soda for a number of months. The mother, and also the grandmother of the patient, had suffered from similar attacks.

DR. BRIDDON could bear testimony concerning the efficacy of phosphate of soda in this class of cases, as he had employed it with apparent success in the treatment of three patients. In one the attacks were markedly severe, and the patient had taken morphine, large quantities of olive oil, and many other remedies. He put her upon the use of one drachm of the phosphate of soda three or four times a day, first recommended, as he recollected, by Dr. Bartholow, and she continued these doses for a long time, and has been free from the attacks ever since.

DR. L. M. YALE remarked that the use of phosphate of soda in hepatic troubles was much older than Dr. Bartholow, and that Dr. Stephenson, of Edinburgh, had, a number of years ago, urged it especially for children, under the conditions in which the gray powder had usually been employed. With regard to the use of olive oil, he thought that it had been determined that the supposed discharge of gall-stones after its use was really due to a sort of saponification of the excess of oil, the masses being usually fatty.

DR. POST was once called to see a lady who was suffering from symptoms of obstruction of the bowels, and on examination he found a solid mass occupying the rectum, which, when scooped out, was found to contain hundreds of pills embedded in hard fecal matter, the whole mass resembling the mineral known as pudding stone.

DR. GEORGE A. PETERS referred to the case of a young lady who took a great number of cathartic pills without any effect, and it was conjectured by some that she did not take them because of the immense number which she said she had swallowed without any result. It was subsequently discovered that she sewed up each pill in a piece of tamarind skin, and she also had an accumulation of undissolved pills.

DR. POST inquired whether, when gall-stones had reached a size sufficient to produce symptoms of obstruction, they passed through the duct directly, or ulcerated their way into the bowel?

DR. MARKOE referred to a specimen in the New York Hospital Museum, in which a large gall-stone had passed partly through the duct, and had there become impacted and remained, seeming to illustrate the possibility of gall-stones of considerable size passing through the duct.

DR. H. B. SANDS believed that when the gall-stone was a very large one, such as would be likely to occasion intestinal obstruction, it never passed through the duct, but always into the duodenum by ulceration, the intestine having become previously adherent. In answer to one of the questions as to gall-stones being seen in the discharges from the bowel, he recalled a case which he saw in consultation with Dr. Chamberlain, in which a lady had been very ill, was jaundiced, and had passed quite a number of gall-stones, probably from six to twelve, and the pain and other symptoms had subsided. What impressed them most was the consistency of these gall-stones, which were faceted, of the diameter of about a fourth of an inch, but were almost as soft as putty. It seemed singular that they should have preserved their shape while passing through the bile-duct.

The late Dr. Parker passed a gall-stone of unusual size, having a diameter of about half an inch. He was very ill before it escaped into the intestine; had great pain, accompanied with jaundice and chills, but his severe symptoms subsided immediately after the passage of the stone; and, so far as Dr. Sands was aware, the patient did not pass any more, nor have any further trouble subsequently from this cause. When his body was examined after death, it was discovered that the gall-bladder was obliterated; there was no cavity, although the site of the bladder could be distinctly seen. The hepatic duct was present, but there was no cystic duct. It seemed probable that, at the time the large gall-stone passed, an ulceration was set up which resulted in the obliteration of the gall-bladder and the cystic duct.

PENDULOUS CELLULO-FIBROUS TUMOR.

DR. C. K. BRIDDON presented a specimen which was interesting chiefly on account of its rarity and size. It was removed from the inner aspect of the thigh, at about its middle, of a woman thirty-five years of age, and had been nineteen years in developing. The entire growth was eight and one-half inches in length, of which four

and one-half inches belonged to the tumor, the rest being the pedicle; the circumference of the tumor was eight inches.

CHICAGO GYNECOLOGICAL SOCIETY.

Stated Meeting, January 16, 1885.

THE PRESIDENT, H. P. MERRIMAN, M.D., IN THE CHAIR.

DR. E. C. DUDLEY read a paper on an interesting and unusual case of

DOUBLE OVARIOTOMY.

The patient, 18 years old, unmarried, came to Mercy Hospital, about eighteen months ago, to consult Dr. Dudley about marked abdominal enlargement. The diagnosis of monocystic tumor of the parovarium or broad ligament was made. The cyst was aspirated, and two gallons of fluid were removed. This fluid possessed the following characters: sp. gr. 1.005; neutral reaction; limpid as water; odorless; colorless; on microscopical examination no morphological constituents were detected; on chemical examination certain mineral salts were found, but no albumen. The patient experienced so much relief, after aspiration, that she left the hospital with the impression she was permanently restored to health. About three months ago, she visited Dr. Dudley at his office. It was found the cyst was partially refilled. An operation was determined upon.

The preparatory treatment of the patient—apart from tonics, the most nutritious of foods, frequent baths, and finally a Turkish bath, immediately preceding the day of operation—consisted in the exhibition of remedies designed to increase the tonicity of the muscular coats of the intestines, and to expel all the gases. For this purpose the patient was given, two or three times daily, a mixture of calumba, rhubarb, and compound tincture of cardamom. In a case, operated upon early in the autumn, Dr. Dudley had experienced much difficulty in the management of the intestines, which were distended with gas. In this case, subjected to the preparatory treatment just detailed, absolutely no difficulty in that direction was encountered. The *mons veneris* was shaved, and the vagina irrigated, immediately before operation. The details of rigidly antiseptic surgery were observed with reference to the operating room, instruments, operator, and assistants.

October 29.—Dr. Dudley, assisted by Dr. W. W. Jaggard, Dr. R. W. Bishop, and Dr. W. E. Casselberry, performed ovariotomy, and removed both ovaries and tubes, together with a large monocyst of the left broad ligament. The pedicle of the large cyst was very vascular, and after transfixion with the passage of the ligature around each half, the operator was compelled to ligature *en masse* below the point of transfixion. The pedicle was afterwards seared above the Baker Brown clamp with Paquelin's thermo-cautery. Ether was employed as the anæsthetic. The patient reacted well. At noon, two hours after operation, temperature 100.7°; pulse 150; respiration 20. She complained of nausea. At night, temperature 100.8°; pulse 115; respiration 20. Nausea continues; no tympanites.

30th.—Morning temperature 100.4°; pulse 112; respiration 20. Evening temperature 101°; pulse 124; respiration 20. Throughout the day the patient moaned and tossed, complained of nausea, vomited incessantly; a peculiar talkative delirium ensued. Morphia and atropine were given to suppress vomiting; discontinued the atropine, fearing its cerebral action. Hot water, as suggested by Mr. Keith, was tried, with hope of checking nausea and vomiting, without success. The deodorized tincture of opium was substituted for morphia. The talkative delirium, nausea, and vomiting, continued unabated. The patient retained only a little ice-water at long intervals.

31st.—Morning temperature 99.8°; pulse 110; respiration 20. Evening temperature 99.8°; pulse 110; respiration 20. Nervous symptoms greatly exaggerated; nausea and vomiting unabated; pain in the abdomen complained of at intervals. Codeia was substituted for the other opiates. Small quantities of milk and lime-water, at intervals, were exhibited. The patient remained in the same condition. Talkative delirium, no sleep, nausea and vomiting, pain in the abdomen at intervals, no tympanites.

Nov. 1.—Morning and evening temperature 99.7°; pulse 106; respiration 20. Talkative delirium, nausea, vomiting of bile—the "mouth-filling" of Mr. Keith—adbominal pain, no tympanites. She commenced to menstruate, or, at least, blood began to escape from the vagina.

2d.—Morning temperature 98.8°; pulse 114; respiration 18. Evening temperature 98.6°; pulse 135; respiration 21. Nervous symptoms more distressing; nausea and vomiting continuing; patient becoming emaciated; face taking on a pinched, anxious expression. Valentine's beef-juice exhibited; mustard to epigastrium; strychnia in small doses; champagne ℥iss.

3d.—Morning, 8 A. M., temp. 101°; pulse 130. 10 A. M. temp. 101.2°; pulse 160. 10.30 A. M., temp. 101.6°; pulse 178. Persistence of wild, talkative delirium, nausea, vomiting, abdominal pain. The pulse, while very rapid, was not the feeble pulse of collapse. In a consultation with Dr. W. H. Byford on the previous day, it was decided that the patient was dying of exhaustion. Dr. Byford was averse to reopening the abdominal incision. Dr. Dudley had one case of peritonitis, following perforation of the posterior uterine wall, in Mercy Hospital, that died of septic poisoning, although the temperature did not rise above 100°.

With the aid of Dr. R. W. Bishop, Dr. Dudley etherized the patient, removed four or five stitches from the lower end of the abdominal incision, and inspected the cavity of the abdomen. The peritoneum was injected; no lymph was noticed; no gas in the intestines. The pedicles were not covered with lymph. A disinfected sponge, on a holder, was passed into the cul-de-sac of Douglas; about one-half of a fluidounce of bloody serum was removed. This red-stained fluid was odorless; it was not further examined. Feeling no good had been accomplished, the incision was reunited. This operation was performed at 10.30 A. M.

Temp. at 12 M., 101°; pulse, 150.
" 2 P. M., 100°; " 144.
" 3 " 100°; " 135.
" 7 " 100°; " 140.

Jactitation, wild delirium, nausea, and vomiting; pain in the region of the cardiac axis; no tympanites. Rectal alimentation.

4th.—Morning temp. 100°; pulse 135–150. Whiskey, beef-tea and milk at regular intervals; bisulphate of quinia per rectum. Persistence of the symptoms before detailed.

In the afternoon the tongue was dry, cracked, ready to bleed; decidedly less nausea and vomiting. The nurse was directed to give the patient an enema of soap and water, with extract of ox-gall. One quart of this mixture was injected into the bowel. No evacuation of the contents of the rectum following, a tube was introduced, which was followed by that classical sign, the audible passage of flatus. Mr. Keith says that if the intestines have sufficient muscular energy to expel flatus, the prognosis becomes more favorable. It is probable a reversed peristalsis occurred, and the injection was entirely absorbed. One hour afterwards the tongue became moist. Evening temp. 101°; pulse 135. Acting on the suggestion from the enema, one quart of strong beef-tea was introduced into the bowel.

5th.—Patient evidently in better condition. Temp., morning and evening, 98–99°; pulse 120–130. One quart of strong beef-juice was exhibited per rectum, and carried well up into the bowel. About three-fourths of this quantity was retained. Slight nausea and vomiting; bowels were moved spontaneously, with evacuation of a large quantity of dark, tarry, fetid feces. The sutures originally inserted, were removed.

6th.—Morning temp. 98.5°; pulse 90. Evening temp. 98.1°; pulse 115. Bowels were again moved spontaneously, with evacuation of dark, tarry, fetid feces, all the symptoms of the patient assuming a favorable character. Beef-tea, whiskey, quinine, and nutrient enemata continued. From this time on, the patient made an uninterrupted recovery. At the end of two weeks she was removed to St. Luke's Hospital. She is now in good health, and pursuing her usual avocation. In conclusion, Dr. Dudley called attention to the three following subjects, and requested that the discussion should be more particularly limited to their consideration.

I. Preparatory treatment of the intestinal tract. Is it possible to render the intestines manageable during an operation in the abdominal cavity, by any dietetic or medical agencies? The escape of the intestines without the abdominal parietes was a very distressing complication. The shock of the operation was increased; large vascular areas were rapidly cooled, notwithstanding the fact that they might be enveloped in warm, disinfected fabrics. It was not always easy to return the intestines to the cavity of the abdomen, and even then there was danger of strangulation. He was of the opinion that, in the case reported, the rhubarb, calumba, and cardamon were active in restoring tonicity to the muscular coats, and in the expulsion of flatus.

II. The retention of enemata. It was a matter of surprise to him that one quart of fluid, exhibited per rectum, on three successive days, should be retained. He supposed that the liquid portions of the injections were absorbed at once, in consequence of the state of the tissues, resulting from exhaustion. The return of the tongue to a moist condition, within a very short space of time, immediately following the injection, was evidence in favor of this explanation.

III. The reopening of the abdominal incision. Had it done any good? What produced the excessive nervousness? What was the cause of the nausea and vomiting?

The problem was an intricate one. It had been asserted that a very tight ligature around the pedicle can act as a reflex irritant. The sutures in the abdominal incision are sufficient, at times, to produce various obscure reflex symptoms. He had one case—his first case—in which uncontrollable vomiting yielded immediately upon withdrawal of a rubber drainage-tube. It may have been that the case reported was just at the point of recovery when the abdomen was reopened.

The fluid removed was small in quantity and without odor. The peritoneum, however, can secrete with wonderful rapidity, and then absorb the secretion. He had not examined the fluid microscopically or chemically. He had dusted into the cul-de-sac a small quantity of iodoform. Whether *post hoc* or *propter hoc*, the patient recovered.

If it was a case of exhaustion, the beef, milk, and whiskey deserved the credit. If a case of sepsis the reopening of the incision was the potent factor. In answer to a question by Dr. Sawyer, Dr. Dudley said that although the delirium of the patient was attended with visions of snakes, alcohol was out of the question, from his own knowledge of the habits of the patient. In answer to Dr. Merriman's question as to the preparation of the ligatures, Dr. Dudley said that silk thread was used exclusively for sutures and ligatures. This silk thread was boiled for ten minutes in a ninety-five per cent. solution of carbolic acid; then for thirty minutes in a five per cent. solution of carbolic acid; finally, it was deposited in a solution of the bichloride of mercury, one to four thousand. Dr. Dudley then exhibited the specimens. The right ovary was slightly enlarged, and in the commencing stage of cystic degeneration. A cyst about the size of a hickory nut was found in the right broad ligament. The left ovary was converted into a mass of fibrous tissue, about the size and shape of a kidney. Springing from the left parovarium or from the left broad ligament was the large monocyst, to which allusion has been made. This cyst, at the time of the operation, contained about forty pounds of fluid.

DR. HENRY T. BYFORD thought that the reopening of the abdominal incision was unnecessary. Relief could not have come from the removal of such a small quantity of fluid as one-half fluidounce. The improvement immediately following the operation was probably due to the stimulant effect of the ether. The delirium seemed to him to be that of alcohol or cerebral anæmia. He did not think that the symptoms of nausea and vomiting could be explained by any local irritant such as ligatures or sutures. It was a case of exhaustion cured by the judicious exhibition of beef, whiskey, and milk.

DR. EDWARD W. SAWYER said that the patient owed her life to the persistent bravery of the operator, and congratulated him upon his success. He was surprised to hear that no albumen was detected in the aspirated fluid. Friedrichs says albumen is always present in such cases, but absent in echinococcus cysts.

DR. F. M. WILDER said that egg albumen in water was frequently tolerated by the stomach when other matters were rejected.

DR. W. W. JAGGARD thought that the secretory and resorptive functions of the peritoneum were matters of

positive knowledge. Dr. Anton Wölfler, in a recent paper, has taken substantially Dr. Dudley's position. It is quite possible that the one-half fluidounce of blood serum, found in the cul-de-sac, represented the ultimate stage of resorption of a much larger quantity of fluid.

One-half fluidounce of fluid, however, may contain enough sepsin, or sufficient bacteria, to produce the most fatal pyæmia. There is no quantitative relation in regard to the virulency of certain poisons.

The mere reopening of the abdominal incision seems to act, under certain conditions, in a favorable manner. The reason is unknown. It is an empirical fact acknowledged by a number of leading surgeons.

He thought Dr. Dudley deserved great credit for his action, in taking up the suggestion of numerous operators, when he knew positively no foreign body was contained within the abdominal cavity.

DR. W. E. CASSELBERRY wished to emphasize the importance of the preparatory treatment of the intestinal tract. He had been present at both of the operations to which Dr. Dudley had referred, and was struck by the difference in the behavior of the intestines. The mixture employed by Dr. Dudley resembled a favorite formula of the late Dr. George B. Wood. This formula was advised for the expulsion of flatus, and restoration of tone to the intestinal muscular walls.

DR. D. T. NELSON said that it was highly important to avoid the use of opium, when it was possible. The less opium, in general terms, the less the tendency to vomiting. As to the pedicle, he entertained grave doubts as to the propriety of passing the ligature *en masse*. In strangulated hernia, uncontrollable vomiting frequently resulted from the inclusion of omentum in the ligature. Would it not be better to open the pedicle, and pass a ligature around each vessel separately? He thought Bantock, Thornton, and Spencer Wells advised the same treatment as in the securing of the vessels in an amputated leg.

DR. SAWYER said that he had seen Dr. John E. Owens remove a testicle; following the passage of the ligature around the cord, uncontrollable vomiting occurred. The reopening of the abdominal incision was looked upon with too much fear. He had been present at an operation in which all the blood had not been removed from the cul-de-sac; the patient died of septicæmia. At the autopsy, Douglas's pouch was filled with blood. An operation might have saved life. Another case, in point, was one of normal, double ovariotomy. After the operation, the patient sank rapidly. The operator concluded the patient was suffering from internal hemorrhage. Twelve hours later, the abdominal incision was reopened, and after two hours' search the bleeding vessels were secured. The patient recovered.

DR. H. P. MERRIMAN endorsed Dr. Dudley's reopening of the abdominal incision in the case presented. In regard to the preparatory treatment of the intestinal tract, he was not certain that the exhibition of calumba, rhubarb, and cardamom had produced the favorable result in the one case, nor that the neglect of preparatory treatment was operative in the troublesome condition in the other. He did not think the opium was the cause of vomiting, since the nausea disappeared while the patient was still under the influence of opiates.

He did not think the ligature *en masse* or the clamp could be replaced by the method suggested by Dr. Nelson. The danger from hemorrhage was too great. It was an admirable subject for study. If the pedicle was completely destroyed, the danger of pinching nerve filaments would be less.

The quantity of fluid removed after reopening the incision was not sufficient to account for the improvement in symptoms.

DR. NELSON referred to the compression forceps, and ligature placed above, as designed to obviate the inclusion of nerves still sensitive.

DR. DUDLEY closed the discussion. The mere opening of the abdomen seemed to act in a remarkable manner under certain conditions. Tubercle of the peritoneum, papilloma of the omentum, were pathological states which had been influenced favorably by the procedure.

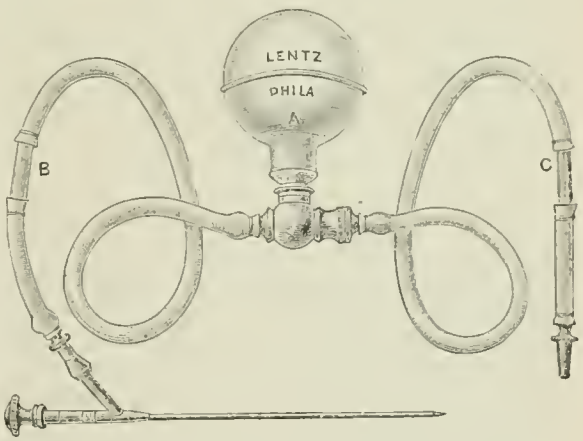
Cocculus indicus is supposed to have the same effect as the mixture exhibited to prepare the intestinal tract. It is not necessary that a discharge should have a foul odor, or be large in quantity, in order to be capable of producing pyæmia.

NEW INVENTIONS.

A NEW ASPIRATOR.

EVERY practitioner has occasional need for an aspirator, but the cost of those thus far placed on the market is such as to deter many from possessing one.

Dr. Frederic Cross, of Kingston, Pa., has devised one extremely simple in construction, which can be used without an assistant, and has thus far answered every demand made upon it. It is manufactured by Mr. Charles Lentz, of No. 27 South Tenth Street, Philadelphia. The accompanying cut illustrates its construction.



In place of an air-pump a strong rubber suction ball A draws the fluid through the canula, a valve prevents regurgitation, and another valve discharges the fluid through the distal tube of rubber. Glass peep-tubes B and C enable the flow of fluid to be observed, while the distal end, if wished, is kept immersed in the dejecta. After evacuating the sac the tube from the canula can be removed, and can be attached to the other end of the tube, which will enable water or a medicated wash to be injected into the cavity. Again, if the tubes be reversed, the cavity can again be evacuated.

CORRESPONDENCE.

COCAINE IN URETHRAL SURGERY.

To the Editor of THE MEDICAL NEWS.

SIR: I send you the following cases from my note-book, with the hope that they may elicit the experience of others in the same direction.

Seminal Weakness. Nov. 25, 1884. Being desirous of faradizing the urethra of W. G., I found the introduction of the urethral electrode prevented by the extreme sensitiveness of the mucous membrane. Having the day before secured a 2 per cent. solution of the hydrochlorate of cocaine, ʒss was slowly injected and retained for a few minutes, labile pressure upon the under surface of the penis being made to distribute the solution. The electrode was then introduced, and passed, without pain, into the bladder. Having been withdrawn to the desired point, the operation was proceeded with without further trouble.

Spasm of the Sphincter Vesicæ. F. R. W., Nov. 30, 1884. Introduction of the urethral electrode for faradization of the muscle was rendered impossible, as the sensitiveness of the mucous membrane just inside the meatus caused the patient intense suffering when such manipulation was attempted. The injection of a 2 per cent. solution of cocaine relieved the condition in five minutes. This patient has been seen by me several times for this same trouble, and I have heretofore relieved the sensitiveness of the urethra by the injection of a weak solution of carbolic acid in glycerine.

Chronic Cystitis. C. A. R., Dec. 20, 1884. Patient has been under observation for several months, and all attempts to treat the case by internal applications of galvanism have been unavailing on account of the pain attendant upon the introduction of the urethral electrode. To-day I employed ʒss of a 2 per cent. solution of hydrochlorate of cocaine; and, there being no amelioration of the sensitive condition at the expiration of fifteen minutes, I injected the same amount of a 4 per cent. solution, which I obtained by evaporating a 2 per cent. solution over a sand-bath. This produced the desired effect in a very few minutes.

Stricture of large Calibre in Spongy Portion. H. S., Jan. 5, 1885. Whole urethral tract very sensitive. Injection of ʒss of a 2 per cent. solution of muriate of cocaine removed the hyperæsthesia from the greater part of the urethra, but produced no amelioration at the seat of stricture. Another injection of the same solution, located as well as possible with a long-nozzle syringe at the strictured portion, failed to relieve the difficulty. The next day, ʒss of a 2 per cent. solution was injected to allay the general hyperæsthesia, followed immediately by the application of a 4 per cent. solution in glycerine to the seat of the stricture by means of a canula and sponge. No relief of the sensitiveness was obtained, but the patient became extremely pale, remarked that it was growing dark, perspiration stood upon his face and hands, and in a moment more he had ejected the partially digested contents of his stomach upon the floor. He soon recovered, and felt no further disturbance.

The above cases are of interest as examples of the value of cocaine in urethral instrumentation, and the last one indicates a field of investigation as to the depth to, and the tissues upon, which this alkaloid acts. The not serious, but decidedly unpleasant, symptoms in the last case are mentioned not that cocaine necessarily bears a causal relation to them, but that they may be remembered as having occurred in conjunction with the application of a 4 per cent. glycerole immediately following the injection of a 2 per cent. solution. I have not determined the existence of an ulcer at the seat of stricture which might account for the symptoms, and I have not developed them at subsequent operations, at which times I have not applied the cocaine so freely.

WASHINGTON.

(*From our Special Correspondent.*)

A BILL CONCERNING THE APOTHECARIES OF THE ARMY AND NAVY.—MR. RANDALL introduced a bill into the House of Representatives with the following provisions:

H. R. 8017. That the apothecaries of both Army and Navy shall receive a commission, those of the Army to have the relative rank of a second lieutenant of infantry, those of the Navy to have the relative rank of an ensign in the Navy.

Sec. 2. That the said apothecaries of both Army and Navy shall not be in line of promotion.

Sec. 3. That the said apothecaries of both Army and Navy shall receive the pay and emoluments of said grades in their respective branches of the service.

Sec. 4. That the said apothecaries of both Army and Navy shall not be entitled to any of the benefits that may be conferred by this Act until they have passed a satisfactory examination in the following branches, namely: Elementary chemistry, materia medica, pharmacy, and botany.

Sec. 5. That the said Board of Examiners shall consist of three medical officers, to be chosen, those from the Army, by the Secretary of War, and those from the Navy, by the Secretary of the Navy.

Sec. 6. That each and every apothecary who shall be serving in such capacity, at the time of the passage of this Act, shall be granted an examination, and if found proficient in the above-mentioned branches, shall receive a commission in that branch of the service to which he may be attached.

Sec. 7. That this Act shall take effect immediately after the passage of the same, or so soon thereafter as the requirements above mentioned in regard to the said Board of Examiners can be met.

THE GARFIELD MEMORIAL HOSPITAL.—A report having been made in the newspapers that this hospital was about to close its doors for want of funds, a statement has been published that its financial condition is not so depressed as has been represented. It certainly is in need of funds, but it is out of debt. Since its opening, in June, 1884 (May 30th, to be more correct), 115 patients have been received, of whom 79 occupied free beds. The Surgeon-General of the Army, Dr. Murray, speaks unqualifiedly in approval of the man-

agement. The ladies who have undertaken to procure funds for the institution are still sanguine of being able to provide the necessary ways and means for its support.

A BILL FOR THE PROMOTION OF ANATOMICAL SCIENCE IN THE DISTRICT OF COLUMBIA passed the House on January 12th, is now before the Senate, and it is hoped will become a law before the close of the present session. In its provisions it is of the first importance to the medical colleges of the District, which this winter have a pretty full attendance, and bid fair to continue in a prosperous condition. The medical department of the Columbian University (the National Medical College) has opened its doors to women during the present session, four of whom have already matriculated. This step was not taken without due deliberation, and the male students do not seem to be disturbed by the introduction of a new element into their midst.

The bill reads as follows:

Be it enacted, etc., That any public officer or officers, whether directors, trustees, superintendents, wardens, keepers, or managers, having lawful charge of, or control over, any hospital, prison, almshouse, jail, morgue, or asylum, within the District of Columbia, may deliver to the duly authorized agent of any medical college or colleges in the said District of Columbia, the bodies of such deceased persons as are required to be buried at the public expense, said bodies to be distributed among the several colleges equitably, the number assigned to each being proportioned to that of its students.

Provided, however, That, if the deceased person, during his last illness, of his own accord, requested to be buried; or if, within twenty-four hours after his death, any person claiming to be, and satisfying the authorities that he is, of kindred to the deceased, asks to have the body buried; or if such deceased person was a stranger or traveller, who suddenly died, the body shall not be so delivered, but shall be buried.

Sec. 2. That every physician or surgeon, before receiving such dead body, shall give to the officers surrendering the same to him a sufficient bond that each body shall be used only for the promotion of anatomical and surgical knowledge within the District of Columbia; and that, after having been so used, the remains thereof shall be decently buried; and whosoever shall use such body or bodies for any purpose other than that aforesaid, or shal remove the same beyond the limits of the said District of Columbia, and whosoever shall sell or buy such body or bodies, or in any way traffic in the same, or who shall disturb or remove bodies from graves in which they have been buried, shall be deemed guilty of a misdemeanor, and shall, on conviction, be imprisoned for a term not exceeding three years, at hard labor, in the District (or city) jail.

The Committee on the District of Columbia recommend the bill in the following words: There are now several flourishing medical schools in Washington well established, and one or more of them of long standing. It is known to all that such institutions cannot be carried on or proper training for the practice of medicine and surgery be given without ample experience in the dissection of the human cadaver. This fact is recognized and approved by all, and yet public opinion as strongly approves and demands stringent laws for the punishment of the desecration of graves in order to procure the necessary dissecting material. Hence the laws of the District are very severe, and properly so, against the crime of grave-robbing. With such laws in operation, and such necessities for the schools of medicine, the authorities of the District are compelled either to wink at this offence or seriously to cripple, if not to destroy, the efficiency and success of these schools. Furthermore, the heads of these institutions, professors and students of science, are compelled to supply their admitted necessities by confederating with and employing professional grave-robbers, and constantly to incur the risk of detection and criminal prosecution; and it being known in a community that the trade of resurrecting bodies for dissection is a common one, kindred and friends are frequently tortured with anxiety lest the hand of the resurrectionist shall remove the bodies of their dead.

This bill is intended to relieve from such fears, to do away with the necessity or temptation for violating the laws, and at the same time in an open and legal way to provide the requisite dissecting material for the study and advancement of anatomical science in the District. A careful comparison with the statutes of some of the States shows its provisions to be prudently and aptly framed, and intended to accomplish the purpose in view, in a manner as little repellant to public sentiment and sensibility as practicable.

A BILL TO REGULATE THE PRACTICE OF DENTISTRY IN THE DISTRICT OF COLUMBIA passed the House of Representatives on January 12. It provides for a board of examiners, and requires them to make proper inquiries into the fitness of all who practise dentistry in the District of Columbia, to issue cerificates of competency, and to keep a full register of dentists so practising. Non-compliance with the provisions of the Act is made punishable by a fine of not less than fifty dollars or more than two hundred dollars, in default of the payment of which, imprisonment for not less than thirty days nor more than ninety days. Nothing in the Act to be so construed as to prevent surgeons and physicians from extracting teeth and prescribing for or treating diseases of the mouth.

YELLOW FEVER.—Surgeon-General Hamilton, of the Marine-Hospital Service, has been informed of the existence of yellow fever in malignant form at Panama and Colon. In a single cemetery at Panama, there have been more than one thousand interments between July and December, and it is estimated that about 2400 people were buried in that city during the year 1884. It is suggested that all vessels coming from Colon and Panama to ports of the United States be watched with extreme care by health officers.

NEW YORK POLYCLINIC.—The Board of Directors and Faculty of the New York Polyclinic held their annual meeting on January 20. The Secretary submitted to the Board a report of the work done by the Polyclinic from its opening, November 7, 1882, to January 20, 1885, giving in detail the history of the organization of the school, its plan of work, and the results achieved. The number of practitioners who had studied

in the Polyclinic as members of the class was 463. The attendance for the present session was twenty-five per cent. in excess of any former year.

A NEW DYNAMOMETER.—At the last meeting of the Philadelphia County Medical Society, Dr. H. Leaman presented a dynamometer, by which he claims he can measure the value of that part of a uterine contraction which is available in the expulsion of the fœtus. It is intended to measure the expulsive force of the uterus minus the resistance in succession of the uterine cervix, pelvic walls, and perineum, and might be called a parturiometer. He thinks it will prove valuable as a means of determining when instrumental interference becomes necessary.

OHIO STATE SANITARY ASSOCIATION.—The second annual meeting of the Ohio State Sanitary Association will be held at Columbus, Ohio, February 5 and 6, 1885.

THE *Lacaze* prize of 10,000 francs has been awarded by the Faculty of Medicine of Paris to M. DEBOVE for his *Clinical Lessons on Tuberculosis*.

NOTES AND QUERIES.

COCAINE IN VAGINISMUS.

To the Editor of THE MEDICAL NEWS.

SIR: In your issue of last week, a statement is given, under "Medical Progress," of the successful application, in Paris, of muriate of cocaine for the relief of vaginismus. At the gynecological clinic of Jefferson Medical College, December 9th, Dr. Henry Morris made such application in a patient suffering from vaginismus, and with a very satisfactory result.

T. P.

PHILADELPHIA, Jan. 23, 1885.

CANADIAN REQUIREMENTS FOR THE DEGREE OF M.D.

IN reference to some remarks in THE NEWS of December 6th, Dr. Panton, of Portland, Oregon, calls our attention to the fact that the University of Toronto has, since 1877, rigidly required four full years for the degree in medicine, not allowing the optional year with a physician still permitted at many Canadian schools.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 20 TO JANUARY 26, 1885.

TREMAINE, W. S., *Major and Surgeon.*—Granted leave of absence for one year on surgeon's certificate of disability.—*S. O. 14, A. G. O.*, Jan. 17, 1885.

MAUS, LOUIS M., *Captain and Assistant Surgeon.*—Granted leave of absence for two months on surgeon's certificate of disability, with permission to leave the Division of the Missouri.—*S. O. 16, A. G. O.*, Jan. 20, 1885.

STEPHENSON, WILLIAM, *First Lieutenant and Assistant Surgeon.*—Relieved from duty at Fort Omaha, Neb., and ordered to Fort Niobrara, Neb., for duty.—*S. O. 6, Department of the Platte*, Jan. 19, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE, FROM OCTOBER 1 TO DECEMBER 31, 1884.

BAILHACHE, P. H., *Surgeon.*—Granted leave of absence for thirty days, Oct. 9, 1884. To proceed to Wilmington, N. C., as inspector, Nov. 10, 1884. Relieved from duty as chief of purveying division; to proceed to Philadelphia, Pa., and assume charge of the Service, Dec. 10, 1884.

WYMAN, WALTER, *Surgeon.*—Granted leave of absence for fifteen days, Oct. 15, 1884. Leave of absence for fifteen days in December, 1884, and thirty days in January, 1885, also for a further period from January 31, 1885, without pay, and with permission to visit Europe, Dec. 8, 1884.

PURVIANCE, GEORGE, *Surgeon.*—When relieved, to proceed to Cincinnati, O., and assume charge, Nov. 12, 1884. To Louisville, Ky., as inspector, Nov. 24, 1884.

AUSTIN, H. W., *Surgeon.*—To proceed to Boston, Mass., and assume charge, Nov. 12, 1884.

SMITH, HENRY, *Surgeon.*—When relieved, to proceed to Cairo, Ill., and assume charge, Nov. 9, 1884. Granted leave of absence until January 15, 1885, Dec. 17, 1884.

STONER, G. W., *Passed Assistant Surgeon.*—Relieved from duty at Delaware Breakwater Quarantine, to proceed to Cairo, Ill., in accordance with former orders, Oct. 14, 1884. To Norfolk, Va., Nov. 19, 1884.

IRWIN, FAIRFAX, *Passed Assistant Surgeon.*—To close Cape Charles Quarantine, October 31, 1884, proceed to Washington, and report to Surgeon-General, Oct. 14, 1884. To take charge of the Service, port of Georgetown, D. C., and detailed as Acting Chief Clerk, Surgeon General's Office, Oct. 30, 1884. To Philadelphia, Pa., and Baltimore, Md., as inspector, Dec. 30, 1884.

MEAD, F. W., *Passed Assistant Surgeon.*—When relieved, to proceed to Baltimore, Md., and assume temporary charge, Dec. 10, 1884.

HEATH, W. H., *Passed Assistant Surgeon.*—Granted leave of absence for thirty days on account of sickness, Oct. 24, 1884. When relieved, to proceed to Pittsburg, Pa., and assume charge, Dec. 26, 1884.

GUITÉRAS, JOHN, *Passed Assistant Surgeon.*—To report to Surgeon-General, Nov. 8, 1884. Leave of absence extended fifteen days without pay, Nov. 14, 1884.

WHEELER, W. A., *Passed Assistant Surgeon.*—Relieved at Chicago, Ill., to proceed to Buffalo, N. Y., and assume charge, Dec. 26, 1884.

BANKS, C. E., *Passed Assistant Surgeon.*—When relieved, detailed for special duty; upon completion of same, to Boston, Mass., for duty, Oct. 28, 1884.

PECKHAM, C. T., *Passed Assistant Surgeon.*—Granted leave of absence for twenty days, Dec. 26, 1884.

BENNETT, P. H., *Assistant Surgeon.*—When relieved, to rejoin his station (Detroit). Nov. 20, 1884.

AMES, R. P. M., *Assistant Surgeon.*—To report to Surgeon Hutton, at Louisville, Ky., for examination for promotion, Nov. 13, 1884.

DEVAN, S. C., *Assistant Surgeon.*—To proceed to Tacoma, W. T., as inspector, Oct. 14, 1884.

KALLOCH, P. C., *Assistant Surgeon.*—Granted leave of absence for thirty days, Nov. 19, 1884.

GLENNAN, A. H., *Assistant Surgeon.*—To proceed to Key West, Fla., for temporary duty, Oct. 8, 1884.

BATTLE, K. P., *Assistant Surgeon.*—Granted leave of absence for thirty days on account of physical disability, Dec. 6, 1884.

BROOKS, S. D., *Assistant Surgeon.*—To proceed to New York, N. Y., for temporary duty, Oct. 20, and Nov. 26, 1884.

WHITE, J. H., *Assistant Surgeon.*—To proceed to New Orleans, La., for temporary duty, Oct. 3, 1884. To escort insane seamen to Government Hospital for the Insane, Dec. 17, 1884. Granted leave of absence for fifteen days, Dec. 23, 1884.

RESIGNATION.

SMITH, HENRY, *Surgeon.*—Resignation accepted by the Secretary of the Treasury, to take effect January 15, 1885, Dec. 17, 1884.

APPOINTMENT.

WHITE, JOSEPH H., M.D., of Georgia, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, Oct. 2, 1884.

PROMOTIONS.

PECKHAM, C. T., *Passed Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury from December 1, 1884, Nov. 28, 1884.

AMES, R. P. M., *Passed Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury from December 1, 1884, Nov. 28, 1884.

DEVAN, S. C., *Passed Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury from December 1, 1884, Dec. 5, 1884.

URQUHART, F. M., *Passed Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury from December 1, 1884, Dec. 5, 1884.

GENERAL ATHEROMA OF THE ARTERIES, WITH PROBABLE THROMBOSIS OF A CEREBRAL VESSEL.

A Clinical Lecture delivered at the Philadelphia Hospital.

BY HORATIO C. WOOD, M.D., LL.D.,
CONSULTING PHYSICIAN TO THE PHILADELPHIA HOSPITAL FOR THE INSANE.

(Reported by William H. Morrison, M.D.)

GENTLEMEN: The case that I show you this morning is in the person of an old Garibaldian, who fought under that General in Rome in 1848, and followed his fortunes in Central and South America. This history is of some medical importance, and we at once draw the conclusion, that we have to deal with a man who has suffered much exposure and led a hard life, and, as he states himself, has been through most forms of dissipation. Thirty years ago, he contracted a chancre which was followed by secondary symptoms. He has always been accustomed to the use of alcohol in considerable quantities. I do not mean that he was an habitual drunkard, but that he used alcohol every day, and was probably always under its influence to a certain extent. He considered himself to be in good health until two weeks ago. At that time, while working at his trade, which is that of a harness maker, he fell to the floor in some kind of a spell. So far as can be made out from careful and repeated questioning, he was not convulsed, and, he thinks, that he did not entirely lose consciousness. Shortly after the occurrence of this spell, the patient suffered from violent headache, and this has been repeated several times since. Headache seems to have been absent previous to the attack.

The points which present themselves for diagnosis are as to the general condition of his tissues and the nature of the spell from which he suffered. Examining the patient somewhat closely, it is at once discovered that he has dimness of vision in the left eye, and that in the right, sight is almost gone. A little further examination shows that this has no connection with the brain symptoms for the simple reason that there is a marked cataract in the right eye. The pupil of the left eye is dilated, and there appears to be a commencing cataract in it.

Taking his hand, in order to feel his pulse, I at once notice that the radial artery is entirely rigid. I have under my finger what appears to be a hard irregular tube. The artery is evidently in a condition of advanced atheromatous change. The change has not advanced so far in the temporal arteries as in the radial, but the vessel is evidently harder than normal. Again looking at the eye, marked arcus senilis is observed in both eyes.

Now, gentlemen, without going further for the moment, let me call attention to the facts which have already been discovered. This man has atheromatous arteries, and he has marked arcus senilis, and in all probability, therefore, he has more or less pronounced atheromatous degeneration of all the arteries. The moment you approach a patient and placing the finger on the pulse, find this hard and rigid condition of the radial, that moment your prognosis, even in what may seem the simplest acute disease, should become doubtful or grave.

In illustration of this point, let me describe a case which I saw last spring. I attended a lady who died from a disease, the nature of which it is not necessary to mention. The day after her death, her husband, who was supposed to be in perfect health, complained of a sore tooth. He said that he had had it filled a few days before and that it was beginning to hurt him. I tapped the tooth with a pencil, and found that it was sore at the root, showing that there was a periodontitis. I advised him to have the tooth extracted. This was on Friday. On Saturday night or Sunday morning, he sent for me, and this was the first time that I had seen the man professionally. I found him with some fever, the tooth was exceedingly sore, and he felt very wretched. I then put my hand on his pulse for the first time, and felt the same condition of artery which exists in the present case. Immediately, it was suggested to my mind that the man had unsuspected chronic renal degeneration, the reason for this suspicion I shall mention directly. I gave a doubtful prognosis, and asked for a specimen of urine. There was at this time apparently nothing the matter but his sore tooth. Examination of the urine showed that it was of low specific gravity and contained albumen, showing that there were contracted kidneys. On Monday he was worse, and on Tuesday he died. He died from septicæmia, resulting from the periodontitis and the small tooth abscess. That man probably had septic poisoning, in part because his system was depressed from the death of his wife, in part because his kidneys were diseased, but largely because the small vessels about the abscess were in a condition of atheroma, and were, therefore, in a state in which they more readily absorbed the inflammatory products.

There are three principal causes for atheroma occurring in middle life. The first of these, and the most frequent in its action, is the excessive use of alcohol. The second is chronic contracted kidney. The third is syphilis. I might add a fourth cause which occasionally produces atheroma, viz., chronic gout. I knew that in the case which I have just described, that there had been no syphilis and no excessive use of alcohol, and therefore my opinion, even before the urine was examined, was very decided that contracted chronic kidney was present.

In the present case, there are at least two of the common causes of atheroma, namely, the excessive use of alcohol and syphilis. The excessive use of alcohol is also very prone to produce chronic contracted kidney. The next thing, therefore, in a case like the present is the examination of the urine for evidences of chronic Bright's disease.

Within the past few years, I have learned a great deal in regard to the latent character of chronic Bright's disease. It has been a number of years since I thought that if albumen was absent from the urine, chronic disease of the kidneys could be excluded. My experience within the last year would lead me to say that in chronic contracted kidney, albumen is absent more frequently than it is present. I do not lay this down as a generalization, which holds in all cases; I simply say that in the run of cases which I have seen during the past year in private practice, albumen has been more frequently absent from the urine than it has been present, when I was certain that the patient was suffering from chronic contracted kidney.

Having progressed in my education so far as to learn that albumen was frequently absent from the urine in these cases, I believed that the condition could be diagnosticated from the specific gravity, and that the urine of a patient with chronic contracted kidney was always of low specific gravity. I think to-day that this is generally the case, and if I had to rely in making the diagnosis on the chemical tests or on the urinometer, I should accept the latter. When a patient passes urine, the quantity of which is not excessive, while the specific gravity is habitually 1010 or 1012, he is in all probability suffering from chronic contracted kidney. I of course leave out of consideration the urine which is passed by hysterical persons. I also stated, that if the urine be not passed in excessive quantity. This is an important point. In the condition known as diabetes insipidus, or polyuria, non-albuminous, non-saccharine urine of low specific gravity is habitually passed, but the daily quantity is measured by quarts.

Having progressed thus far in my knowledge of the diagnosis of this condition, I had yet to learn with considerable chagrin that chronic contracted kidney, bringing the patient even to the grave, may be present, and yet the urine be perfectly normal. I have seen two cases in which the urine had been repeatedly examined by other physicians, and in which I had myself carefully examined the urine, not only for albumen and tube-casts, but also in reference to the specific gravity, and nothing whatever indicating the presence of disease of the kidney was found. In one of these cases, my diagnosis was that the patient was suffering from gastric vertigo, and I treated her for awhile for this condition and gave some relief. She then passed from observation. I was shortly afterwards summoned hurriedly to her home where she had been under the care of another physician. She was then suffering with convulsions, which had been pronounced to be hysterical. The moment I saw the patient, I said, "These are not hysterical convulsions. The patient will be dead within thirty-six hours." I did not know what the trouble was, unless I had made the mistake of saying that there was no brain tumor, when such a growth was present. The autopsy showed that she had died of chronic contracted kidney. There had been no dropsy, no atheroma, no increase of the arterial pressure, nothing abnormal in the urine, and yet the woman died of chronic contracted kidney.

Shortly before this, I was called to one of the northern counties of this State to see a lady suffering from acute dementia. I knew that the woman was gouty, and I asked her physician if he was sure that there was no contracted kidney. He had examined the urine repeatedly and found nothing abnormal. In order to be perfectly certain, I examined it at the time. The specific gravity was above normal; there was no albumen, no tube-casts, but a considerable quantity of triple phosphates. I ruled the possibility of contracted kidney out of the question. Six or eight weeks later the woman died, and the autopsy revealed chronic contracted kidneys.

We are, therefore, brought face to face with the fact that in any obscure case, the presence of chronic Bright's disease cannot be excluded because the urine presents nothing abnormal. This is somewhat embarrassing, because in a large proportion of chronic cases the diagnosis can only be made by exclusion, and therefore if that on which we have so long relied to enable us to exclude renal disease fails us, what are we to do? I believe, however, that this condition of normal urine is not permanent in these cases, and that frequent examinations will enable us to detect enough abnormality to excite or confirm our suspicions. It should in such cases be examined for albumen after a heavy meal, especially of meat, and for specific gravity in the morning after a light supper. After a heavy meal of meat, there is an enormous strain on the kidneys. I never fully appreciated this strain until I came to measure in the dog the effect of large amounts of meat on the heat-producing function. I found that the dog when gorged with meat would produce twice its normal hour-rate of heat. In other words, a large proportion of the meat was immediately burned up and had to be eliminated by the kidneys. I have noticed in some cases that long before there was any reason for suspecting Bright's disease that occasionally, under exceptional strains, the urine would be albuminous. Under such circumstances, my opinion is that the person is in the formative stage of Bright's disease. If you find a person in whom the administration of drugs, the use of alcohol or excessive feeding causes even a temporary albuminuria, you have a patient who, unless proper treatment be instituted, is in all probability going to die of chronic Bright's disease, ten or fifteen years later. Therefore, in any doubtful case, the urine should be examined after a heavy meal for albumen especially, and in the morning, after a light supper, for specific gravity; for when albumen is presen , the specific gravity is least apt to be disturbed. To sum up, then, the presence of chronic Bright's disease is always to be suspected in patients with atheroma. The urine is next to be examined for albumen and its specific gravity noted. If albumen and an habitual low specific gravity be found, there is reason for diagnosticating chronic contracted kidney. If the urine be normal, the examination must be repeated with urine passed after a hearty meal, and in the morning after a light supper.

I shall proceed to apply these principles to the present case. I have here the urine which has been recently passed. Its specific gravity is 1013. Yesterday it was 1024, and non-albuminous. To-day the specific gravity gives reason for suspecting Bright's disease. I next test it for albumen by nitric acid, but I find no albumen. I think it probable that the man has chronic contracted kidneys. The reasons for this view are the history of the existence of the causes of this affection, the condition of the arteries, and the low specific gravity

of the urine. All these facts excite our suspicion, but do not enable us to make a positive diagnosis.

Passing by this portion of the case, we come next to inquire what was the nature of the attack which the man had two weeks ago. I examine the heart. There is no murmur, but there is that peculiar clanging, second sound, which I believe is very frequently associated with atheroma of the aortic arch, and I have no doubt that the man has an atheromatous aorta. We are, however, unable to connect this attack with a fainting fit.

The next thing to be done, is to discover, if possible, the existence of any local palsy. There is no distinct ocular paralysis, the only abnormality being excessive contraction of the right pupil. The left pupil is dilated, but this may be the dilatation of blindness. There is no paralysis of the muscle which raises the upper lid, and the pupil is not sufficiently dilated for oculo-motor paralysis. The right pupil does not respond readily to light. Applying the test of pinching the neck, some dilatation of the pupils takes place, and therefore the reflex is not abolished. There is no palsy in the hands or legs.

We find, then, to-day no evidence of any advanced brain disease; and in the absence of any account of the character of the attack, the diagnosis is uncertain. He may have had a fainting fit, or there may have been a partial loss of consciousness from thrombosis of one of the cerebral arteries, owing to its atheromatous condition; for thrombosis of a cerebral artery is almost always the result of atheroma. This man may have had a stopping up of one of the small vessels of the brain produced in this way, thus temporarily shutting off the blood supply of a small portion of the brain, and causing loss of function, which was regained when the blood found its course again by a solution of the partially coagulated fibrin.

The practical point, so far as the present aspect of the case is concerned, is that this man is suffering from a general tissue change, which is probably the result of a combination of causes. Syphilis, alcoholic excess, exposure, and probably contracted kidneys, have undoubtedly all played a part in the production of this general atheroma.

Curative treatment is, of course, not possible, but it is much to direct such a life aright. The life which this man has led, has made him old beyond his years. Atheroma is the almost normal condition of the arteries of the aged. Chronic contracted kidney, to a greater or less extent, exists in a large proportion of the aged. The treatment is that which is required in the case of old people. A little exposure or over-fatigue may cause pneumonia or general exhaustion; the abuse of alcohol, over-eating, a checking of perspiration, or exposure to cold, may lead to congestion of the brain or of the kidneys. So I might go through the whole system, showing that a little exposure or strain on any part may result in an acute disease, rapidly ending in death.

In the old, or in the prematurely old, protection is the great desideratum. Exposure, over-eating, and the excessive use of alcohol are to be avoided. There seems to be some truth in the old belief, that apoplexy is especially prone to occur in those who sleep after heavy eating. In old persons with atheromatous arteries, the afternoon nap is better dispensed with.

As far as medicines are concerned, this man needs but little. There is no use in stimulating the appetite, for the danger is in excessive feeding. If the kidneys fail in their function, or if the skin be not sufficiently active, proper functional stimulation should be employed; but the ideal treatment is carefully to run the man on a plane from which all disturbing activities are excluded.

ORIGINAL ARTICLES.

ON A NEW VARIETY OF CHRONIC NASAL CATARRH.

By HARRISON ALLEN, M.D.,
PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY OF PENNSYLVANIA.

In a small proportion of sufferers from nasal catarrh, the mucous membrane which lines the nasal chambers is thin, and exhibits scarcely any erectile power. It is abundantly supplied, however, with arterial blood, and is everywhere of a uniform light pink color. A highly polished probe placed in the nasal chamber will cause diffuse reflections to appear on the membrane. The nasal septum, as a rule, is without marked nasal deflection, but may be greatly thickened.

The membranes, especially those at the upper portions of the chambers, upon the gentlest manipulation are apt to bleed slightly; the nostrils are not infrequently excoriated, especially in winter. The discharge is mucoid in character when the disease is mildest, but easily becomes turbid upon slight vascular excitement. During the height of an acute attack (which the patient is apt to call "a fresh cold," and which in females is occasionally coincident with the menstrual period), it becomes purulent. The discharge passes into the throat as readily as from the nostrils.

The pharynx is always capacious, the muscular structures active, and the palato-pharyngeal folds well drawn out to the sides. The uvula is always small and sometimes rudimental, presenting the appearance of having been amputated. The mucous membrane is of a pale color, while the larger veins are numerous. At the sides of the pharynx below the tonsils, the peculiar pearly white color characteristic of the alveo-lingual groove, is seen. The tonsils are always small and drawn out to the sides of the pharynx; they are usually not seen, unless the palato-glossal fold at first is retracted.

The tongue is clean and the closed glands at the base are few in number, inconspicuous, and permit the longitudinal superficial veins of this portion of the tongue's surface to be unusually well seen. The veins of the mucous membrane of the cheek, which lie on the space between the orifice of the duct of Steno and the reflection from the mucous membrane from the cheek to the alveolar process, are large, superficial, and coarsely reticulated.[1]

The pale color of the anterior surface of the soft palate extends forward, and is continuous with that of the hard palate without any change. The hard

[1] The buccal veins here described have been neglected by anatomists and clinicians. They are of importance in studying conditions of vascularity in the mouth, nose, and throat.

palate itself is exceptionally pale, and the positions of the palatine veins may be determined by bluish streaks on the membrane

The posterior or palatal portion of the hard palate in the median line is almost invariably marked by a sessile exostosis, ordinarily two-thirds of an inch in length and one-third of an inch in breadth, although sometimes larger. Extending from the anterior border of this exostosis to the position of the rugæ, is a pronounced median ridge, sometimes the seat of a second exostosis, which is marked in the centre by a minute lineal groove. In two cases which I have seen, the palate was highly arched, and a large congenital opening existed in the anterior portion of the nasal septum.

The subjects of this form of catarrh, as far as I have observed, very commonly have fair skins, are of spare habit, with a tendency to gray or blue eyes, and light-brown hair. The general circulation is never good; the hands and feet are apt to be cold. There is, very generally, a history of tuberculosis, either in the immediate family, or in the families of the parents, although I have never seen the disease coexist with phthisis.

In examining a case of catarrh of this variety, which had never been subjected to local treatment, the under surface of the narrow middle turbinated bone is often found covered with a thin layer of fibrinous exudation; but in all cases, whether this be present or not, firm pressure of the probe against the ledge-like surface will cause the spot which is pressed upon to become instantly of a bright red color. This is a characteristic sign, and a most valuable one in determining the presence of the condition described. In attempting to make an examination of the posterior nares, it is often found that, in spite of the liberal diameters of the pharynx, it is very difficult to obtain a view. The difficulty arises from the fact that the powerful levator-palati muscles pull up the soft palate, and persistently narrow or entirely close the opening of communication between the naso-pharynx and the oro-pharynx.

This form of catarrh may be easily distinguished from that of any other variety; for, so far as I know, the group of signs and symptoms above given under no other circumstances coexist. In catarrhs accompanied with inflammatory extravasations or œdema, the pharynx is of a dusky-red color, and the anterior border of the reddened soft palate is sharply limited from the paler hard palate.

The exceedingly sensitive character of the nasal mucous membrane, and its disposition to slight bleeding from trifling causes, the absence of the erectile tissue, or its rudimental character when present, a nearly straight septum (hence the absence of nasal obstruction),[1] form a group of characters which may be easily recognized.

This form of the disease is not common. I have had the opportunity of carefully studying twenty cases.

The prognosis for cure is unfavorable. In seventeen cases, very marked alleviation followed treatment, while in three no benefit followed the most carefully devised and systematic treatment. I have reason to believe that in these three cases, the failure could be largely attributed to hereditary peculiarities, the results of tubercular history. In one case three grandparents and a maternal aunt had died of consumption. In another, all members of the family had had "weak throats," a maternal aunt and uncle, and a paternal aunt dying of phthisis. The third case was complicated with neurasthenia. The remaining cases were greatly benefited by applications of a saturated solution of nitrate of silver over the more hyperæmic portions of the mucous membrane. This agent, when used with care on a surface not larger than a duck-shot, at a single sitting, is readily borne, and is often followed by the most satisfactory results. I am in the habit of first covering the middle surface of the turbinated bone with these applications, and repeating them every other day. The galvano-cautery under no circumstances is to be used. It is in this class of catarrhal cases that I have found the oleo-resin of cubebs of advantage; indeed, in my experience it is the only form of catarrh in which that preparation is of any use. The agent can be lightly painted along the sides of the chamber, care being taken that it does not trickle into the pharynx. Minute doses of arsenious acid in conjunction with cod-liver oil and oleo-resin of cubebs, are well borne, particularly in the winter months

This form of catarrh is closely allied to ozæna. I remain under the impression that the distinction between the disease and ozæna, remains one of grade rather than one of distinction in kind. While I have never seen ozæna associated with the disease, the characters of ozæna appear to be a high grade of inflammatory state, associated with a disposition to fibrinous exudation, engrafted upon the general features of the phase of nasal and pharyngeal distress as here described.

[1] A sense of obstruction is sometimes referred to the plane of the middle turbinated bones, or obstruction to breathing may be reported as occurring during the night, especially during sleep. In the main, the statement is correct that the turgescence of the mucous membrane is insufficient to close the nose.

DISINFECTANTS.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

II.

COMMERCIAL DISINFECTANTS.

BY GEORGE M. STERNBERG, M.D.,
SURGEON U. S. A.

In conducting the experimental investigations of the Committee on Disinfectants, the writer determined at the outset, in the interest of health officials and of the public, to ascertain the comparative value of the various commercial disinfectants in the market. In a recent paper by Wynter Blythe, Medical Officer of Health for Marylebone, in which the commercial disinfectants, exhibited at the London Health Exhibition, are intelligently discussed, we find the following:

"Rampant rides the quack in the fields, both of preventive and remedial art. Quackery takes a well-

known common powder, labels it with a grand mystic name, selling bright copper at the price of gold. Quackery finds a stink outstinking feebler stinks, and gives it forth as a disinfectant. Of all the substances gathered together under the name of disinfectants—solids, vapors, gases, and odors—a small percentage alone possess any value."[1]

This statement applies as well to many of the articles advertised as "disinfectants" in this country. But in justice to the manufacturers of these so-called disinfectants, we must say that many of them which are of no use in the sense in which we use the term are valuable as antiseptics, or as deodorizers, and that there is good authority for calling a substance which will prevent putrefactive decomposition, or which will destroy bad odors, a disinfectant. Many chemists and physicians use the word in this sense, and this is the popular acceptation of the term both in this country and in Europe. We, therefore, cannot find fault with those manufacturers who see fit to use the word as synonymous with deodorizer or antiseptic, but we must caution the public that a disinfectant from this point of view does not necessarily destroy infectious material; and that the word is used by this Committee in accordance with the definition given by Dr. Rohé in the preceding paper.

It has been proved that certain kinds of infectious material owe their infecting power to living microorganisms, which in a general way are often spoken of as "germs." A disinfectant, therefore, which destroys this kind of infectious material may be called a *germicide*. If all infectious material owes its specific infecting power to the presence of living organisms, then, from our point of view, disinfectant and germicide are synonymous terms. But in the absence of satisfactory proof that such is the fact, we must consider the former term one of general application, while the latter is only applicable in those cases in which the infecting agent has been proved to be a germ. But in our tests of disinfectants we are obliged, for the most part, to depend upon experiments which determine germicide power and in the experiments reported below, only biological tests have been used. As a matter of fact, those agents which by laboratory experiments have been proved to be the most potent germicides, have by the experience of sanitarians, by tests upon vaccine virus, septicæmic blood, etc., been shown to be the most reliable disinfectants.

Evidently there can be no partial disinfection; either the infecting power of the material to be disinfected is destroyed, or it is not. Where the object is to destroy disease germs in the sputum of patients with diphtheria, in the discharges of patients with typhoid fever, etc., so that no development shall occur when these germs find a proper nidus, incomplete destruction will be a waste of ammunition, for so rapid is the multiplication of these low organisms that the question of numbers is of secondary importance. It is therefore essential, in an experimental inquiry of this kind, that the most rigid tests may be applied, and that we keep on the safe side in the practical application of those agents which withstand these tests.

[1] Med. Times and Gaz., London, Oct. 11, 1884.

In our experiments below reported, the material which has served to test the germicide power of the agents named is "broken-down" beef-tea, exposed in the laboratory for several days, and containing a variety of putrefactive bacteria and their spores. The spores of *Bacillus subtilis* are also invariably present in this stock, and when a certain agent is successful in destroying all other microörganisms, we frequently have in our culture-solutions a pure culture of this bacillus, which is noted for its abundant and wide distribution, and for the great resisting power of its spores. In order to meet the objection of those who are likely to cavil because no "disease germs" are present in the material mentioned, a culture of *Bacillus anthracis* containing spores is added to this stock solution. It is well known that anthrax spores constitute one of the most difficult tests of germicide power; not more difficult, however, than the spores of *B. subtilis*. We may safely assume, then, that an agent which will destroy these spores will also destroy all known disease germs, and probably all organisms of this class, known or unknown. The micrococci and bacilli not containing spores are far more easily destroyed.

The time of exposure to the disinfecting agent in all of these experiments has been two hours. And the amount of material to be disinfected has in every case been made equal to the amount of the solution of the disinfecting agent under trial. Thus to test an agent in the proportion of fifty per cent., a certain quantity—10 cc.—of the agent undiluted (100 per cent.) is added to an equal quantity of the broken-down beef stock described. If we wish to test the agent in the proportion of four per cent., an eight per cent. solution is made, and this is added to an equal quantity of the stock, etc. The mixture is placed in a wide-mouthed bottle containing 25 cc. and is set aside for two hours. A minute quantity of the material is then introduced into two little culture-flasks[1] (all experiments are made in duplicate) containing sterilized beef-tea, and these are placed in the oven, which is kept constantly at a temperature of 36° to 38° C. (96.8° to 100.4° F.). My method has been explained in detail in a paper relating to an extended series of experiments of a similar nature, published in the *American Journal of the Medical Sciences* for April, 1883.

These experiments on commercial disinfectants have been very carefully made, under my direction, by Dr. Duggan. The samples were, for the most part, obtained for me by Dr. Raymond, Health Commissioner of Brooklyn, in the cities of New York and Brooklyn. As the experiments are made in the interests of the public, special pains have been taken to secure samples such as are placed in the market, and the rule was adopted at the outset not to test samples sent to us by the manufacturers, but to purchase ourselves such packages as are offered for sale by druggists and other dealers.

Numerous experiments were made, but only those are recorded here which fix the limits between suc-

[1] The flasks used are all made in the laboratory, and are of the form described in the chapter on Technology in my book—*Bacteria*.

cess and failure. In four instances, a failure occurred in the proportion of 50 per cent., *i. e.*, when the undiluted solution was added to an equal quantity of the test-material. These agents were at once dropped without further trial. In the table, the agents are arranged with reference to their relative efficiency.

List of Commercial Disinfectants Tested.

Name upon Label.	Per cent. in which active.	Per cent. in which failed.
Little's Soluble Phenyle (Morris, Little & Co., Brooklyn),	2	1
Labarraque's Solution (*Liq. sodæ chlorinatæ*); name of manufacturer not given.	7	5
Liquor Zinci Chloridi (Squibb's),	10	7
Feuchtwagner's Disinfectant (L. Feuchtwagner & Co., New York),	10	8
Labarraque's Solution (from Freré, Paris),	15	10
Phenol Sodique (Hance Bros. & White, Philadelphia),	15	10
Platt's Chlorides (Henry B. Platt, New York),	20	15
Girondin Disinfectant (James Meyer, Jr., New York),	25	15
Williamson's Sanitary Fluid (D. D. Williamson, New York),	25	20
Bromo-chloralum (Bromo-chemical Co., New York),	25	20
Blackman Disinfectant (Blackman Disinfectant Co., New York),	30	20
Squibb's Solution of Impure Carbolic Acid (about two per cent.),		50
Burchardt's Disinfectant (J. H. Harty & Co., New York),		50
Phenol Sodique (7 Rue Coq. Héron, Paris),		50
Listerine (Lambert & Co., St. Louis),		50

I append to this list the report made by Wynter Blythe (loc. cit.) upon certain commercial disinfectants exhibited at the London Health Exhibition:

"*Various tar-acid disinfectants.*—Jeyes's perfect purifier, the concentrated carbolated creasote of Messrs. D. & W. Gibb, the kresylene described by Messrs. Mackay & Co. as a preparation of coal-tar creasote, pixene, and the thymo-cresol exhibited by Messrs. Ness & Co., have all the property of emulsifying with water. Jeyes's purifier was for some time tried in St. Marylebone urinals and drains, but the deposit left on the surface with which it had been in contact was found difficult to cleanse and inconvenient. I have made some experiments on anthrax in the spore state with the 'perfect purifier.' The solutions used were five to ten per cent.; the 'fluff' had to be freed from the tenacious fawn-colored deposit by alcohol. The result was very similar to what might have been predicted from results of experiments on the pure tar-acids, viz., growth was a little delayed, but never destroyed."

"Mr. James Wheeler's pixene I was on the whole favorably impressed with. He claims to have condensed the whole of the volatile constituents of pure tar, and to have presented them in a form readily miscible with water. . . . Anthrax spores soaked in a ten per cent. solution did not grow for some time."

"*Carbolic acid powders.*—I have experimented on anthrax with Calvert's, Jeyes's, and McDougall's powders; but even when a paste was made with the several powders, and the infected "fluff" allowed to remain therein twenty-four hours, no sterilization resulted."

Similar powders were obtained by our Committee in New York and Brooklyn, but I have not thought it worth while to make any experiments with them, as sawdust, or other material, saturated with impure carbolic acid, or with the volatile constituents of tar, can have no great value, in view of the low disinfecting power of these agents minus the sawdust. An agent which has gained considerable reputation in England is referred to as follows by Blythe:

"*Sanitas.*—Of all the substances introduced under the name of disinfectant, this is the most pleasant. Sanitas is chiefly in the form of sanitas oil and sanitas fluid; peroxide of hydrogen, thymol, camphoric acid, and terebene enter into their composition. Of the numerous sanitas preparations, liquid and solid, the oil seems to be the most active. Nothing replaces or destroys so rapidly the unpleasant odor which tenaciously adheres to hands contaminated by offensive animal matters. It is also to be commended for use in stables, and as a corrective for dung-heaps, and of the sickly smell at times rising from the Metropolitan wood pavement. I made many experiments with sanitas on anthrax. Spores soaked in sanitas fluid for twenty-four hours grew afterwards very freely. Spores placed in the undiluted emulsion, and afterwards removed, seemed at first to have their growth delayed, but in forty-eight hours growth commenced, and ultimately became luxuriant. The oil itself gave similar results. Sanitas powder was also tried, but with no better success."

Returning to the disinfectants in our list, it will be seen that all but the four last-named are efficient in various amounts, ranging from 30 to 2 per cent. But the relative value of the agents as here given does not establish their comparative practical value as disinfectants. Questions of cost, physical and chemical properties, etc., come into the account which it is the province of other members of our Committee to consider. The agent at the head of the list, for example, notwithstanding its superior germicide power, does not seem to me to be as useful as some of those below it, on account of its insolubility and comparatively high price.

We have nothing to say against the use of any of the agents in our list as antiseptics or as deodorizers. No doubt all of them are more or less useful for this purpose, and we have no desire to restrict their use.

But the exaggerated claims made in relation to the germicide, or disinfectant power of certain of these agents, may do immense harm. Thus, one agent advertised as a "germicide" *par excellence*, "Pasteur's marvellous disinfectant," failed *after two hours' exposure* to kill the organisms in our test-solution in the proportion of twenty per cent. Yet this fluid is, by some contrivance, to be thrown into the water-closet of every germ-fearing citizen when he pulls the handle, so that it may catch the germs on the fly and extinguish their power for mischief before they reach the sewers. On the whole, the proprietary disinfectants have turned out better than I anticipated, and any one of the eleven first-named may be used in conformity with the conditions imposed by the experimental test for disinfecting sputum or excreta. For fecal matter, however, it will be best to employ an agent which is successful in the proportion of ten per cent., for example, in at least twice this strength, and in quantity considerably in excess of the material to be disinfected. It must be remembered that in our experiments the germs are suspended in a fluid and this is thoroughly mixed with the disinfectant.

The second agent in our list is the well-known *liquor sodæ chlorinatæ*.

Our experiments lead me to think that this time-honored disinfectant is worthy of more attention than it receives to-day, when so many other agents of inferior value are being pushed by enterprising manufacturers. Our two samples differ greatly in their disinfecting power, which depends upon the amount of sodium hypochlorite present. Dr. Duggan has prepared, and experimented with, a solution containing six per cent. of available chlorine, which proves to be efficient in the proportion of one per cent. I am informed that a solution containing two per cent. of available chlorine could be put in the market for less than forty cents per gallon. Whether this is to be the disinfectant with which we shall fight cholera, must be determined by my colleagues who take up the question from a practical standpoint. But whatever agents are determined to be the best, must be so cheap that they may be obtained by the gallon and used without stint. The time has passed when *pater familias* can complacently congratulate himself upon having disinfected his house with a bottle of carbolic acid which he has brought in his vest-pocket from the corner drug-store.

In view of the efficiency and cheapness of the hypochlorites, I have requested Dr. Duggan to give special attention to these agents, and to prepare a report embodying the results of his biological tests, and such information relating to the *modus operandi*, chemical characters, and available tests of strength, as may be useful to health officers and to the public.

REPORT ON THE GERMICIDE POWER OF THE HYPOCHLORITES.

BY J. R. DUGGAN, M.D., PH.D.,
FELLOW BY COURTESY IN THE JOHNS HOPKINS UNIVERSITY.

IN my previous work on commercial disinfectants, I found that the specimens of Labarraque's solution of sodium hypochlorite, although containing only a small quantity of this salt, were among the most effective in their action. On looking over the literature of the subject, I found that although this solution and that of the corresponding calcium salt (chloride of lime) were among the first used disinfectants, very little had been done to fix accurately their value. In order to determine this, I prepared standard solutions of sodium and calcium hypochlorites for use in the following experiments. The available chlorine, that is, the chlorine which enters into the constitution of the hypochlorites, was determined in these solutions by its oxidizing action on a standard solution of arsenious acid; papers saturated with starch paste and potassium iodide being used to show an excess of the hypochlorite. The well-known method of Dr. Sternberg was used throughout the investigation to determine germicidal value. The following solutions were prepared:

Solution A: Sodium hypochlorite made by passing chlorine gas into a solution of sodium hydroxide. Available chlorine = 6 per cent.

Solution B: Calcium hypochlorite made by passing chlorine gas into milk of lime. Available chlorine = 6 per cent.

Solution C: Calcium hypochlorite made by dissolving 100 grammes of bleaching powder (chloride of lime) in 1 litre of water, and filtering. Available chlorine = 2.4 per cent.

Solution D: Potassium hypochlorite made by passing chlorine gas into a solution of potassium hydroxide, and diluting until the available chlorine = 1 per cent.

The action of Solution A on spores of *Bacillus anthracis* was tried with the following result: 2 per cent. was effective in 30 minutes, 1 hour, and 2 hours; 1 per cent. failed in 1 hour, effective in 2 hours.

Solution B in 2 per cent. gave similar results. In 1 per cent. it was effective in both 1 and 2 hours.

Solutions A and B were both found to be effective in 5 per cent. and 1 minute's time on the organisms of broken-down beef-tea. One-half per cent. of these solutions failed to destroy in 2 hours organisms in broken-down beef-tea, but 1 per cent. of Solution A was effective in the same time. One of the bulbs from a 1 per cent. solution of Solution B broke down, but the other remained clear. These solutions were also tried in 2 and 3 per cent. for 2 hours and found effective.

Solution C was effective in 3 per cent., but failed in 1 and 2 per cent. in 2 hours.

Solution D was effective in 7 per cent., but failed in 5 and 6 per cent. in 2 hours.

In addition to these, we may mention a dilute solution of bleaching powder of unknown manufacture. This contained 0.4 per cent. available chlorine, and was effective in 15 per cent., failed in 10 per cent.; time, 2 hours. The commercial specimens of Labarraque's solution, reported among the commercial disinfectants, showed about the same value in proportion to the available chlorine they contained. These latter experiments were all made on broken-down beef-tea. That this contained spores as well as organisms, was shown by the fact that tubes inoculated from the solution while boiling developed various bacilli. Of course, spores must have been present to resist this temperature.

While it has been thought well to use a pathogenic organism in some of these experiments, I am convinced, from recent work on the subject, that any agent that will destroy *Bacillus subtilis* will also destroy *B. anthracis*, and probably any other pathogenic organism.

The foregoing experiments show that a solution containing 0.25 of 1 per cent. (1 part to 400) of chlorine as hypochlorite is an effective germicide even when allowed to act for only one or two minutes, while 0.06 of 1 per cent. (6 parts to 10,000) will kill spores of *B. anthracis* and *B. subtilis* in 2 hours. A simple calculation will show that all the solutions used were effective when diluted to about this strength, and failed a little below it. No better evidence could be had of the reliability of the excellent method of Dr. Sternberg for testing agents of this kind. These experiments were all made in duplicate, and they show a concordance which I am satisfied can be obtained by no other method with which I am acquainted.

The value of the various commercial preparations, such as Labarraque's solution and bleaching powder (chloride of lime), of course depends on the amount

of available chlorine they contain, since the chlorides and chlorates are of very little value as disinfectants. Bleaching powder usually contains from twenty-five to forty per cent. of available chlorine. For most purposes, a solution containing 1 part of this preparation to 100 of water is strong enough, for this will contain from 0.25 to 0.40 of one per cent. of chlorine as hypochlorite. As is stated above, the smaller of these quantities is sufficient to destroy spores almost instantly. There are very few purposes to which disinfectants are applied that are not fulfilled by this solution of 1 to 100 of bleaching powder. It is not poisonous, does not injure clothing, bedding, etc., and is almost without cost, since bleaching powder is worth only about five cents per pound. The sodium salt furnishes in some respects a more elegant preparation, since it leaves on evaporation sodium chloride instead of the hygroscopic calcium chloride. If prepared according to the U. S. P., it does not keep very well, but when made by passing chlorine gas into a solution of an excess of caustic soda, it shows very little tendency to undergo decomposition. Solution A, although rather concentrated, and frequently exposed to the light and air, has kept for a month without any appreciable change. A solution like this might be put on the market at a very reasonable price, and as it should be diluted with twenty parts of water, it would be far cheaper and more effective than any of the proprietary disinfectants. The odor of the hypochlorites is a slight objection to their use, but in dilute solution this is scarcely disagreeable. Where the odor is not to be regarded, the hypochlorous acid may be liberated by the addition of any common acid, thus increasing the oxidizing power, and liberating a most effective gaseous disinfectant. I hope to make further experiments on this point at an early day.

To fix the value of solutions of the hypochlorites, the following method is sufficiently accurate for ordinary purposes. A standard solution of potassium arsenite may be made by diluting seven parts of Fowler's solution with one and a half parts of water. This corresponds to a one-half per cent. solution of available chlorine. To apply the method, a given volume of the hypochlorite solution is measured out, and the arsenite solution added in small quantities. Between each addition the mixture is well stirred, and a drop taken out on a glass rod and tested on a strip of paper saturated with iodide of potassium and starch paste and dried. As long as any hypochlorite is present, the blue iodide of starch is formed; but when it has all been used up in converting the arsenite into an arseniate, the paper will remain colorless. As each volume of the potassium arsenite solution required for this corresponds to one-half per cent. of available chlorine, the calculation is very simple, *e. g.*, if one volume of the hypochlorite solution = 4.6 volumes of the arsenite solution, the amount of available chlorine present would correspond to 2.3 per cent. Since the preparations now on the market vary so much in the amount of chlorine they contain, this test should always be used to determine their value, and the amount of dilution required. Where the disinfectant is further diluted in use by being added to liquids or semi-solids, the original dilution should not be so great.

The hypochlorites possess the advantage over many of the metallic salts of not forming a coating of insoluble albuminoid matter around solid or semi-solid masses, and thus protecting them from further action. On the contrary, when used in moderately strong solution, they oxidize and disintegrate these materials. They are at the same time destroyed themselves in the reaction, so that we are rid of germs, organic matter, and disinfectant all at the same time.

ABSORBENT COTTON AS AN ELECTRODE COVERING—A SUGGESTION IN ELECTRO-THERAPEUTICS.

By G. BETTON MASSEY, M.D.,
Electro-therapeutist to the Infirmary for Nervous Diseases, Philadelphia.

To practical workers in medical electricity the covering of the metal electrodes used to convey currents to subdermal tissues is a matter of more than apparent importance. The object of this covering is the maintenance of water, or a saline solution, in a position to conduct the current painlessly from the metal surface through the epidermis (which is a very poor conductor in a dry condition) to the moister tissues below. This covering should be thin, yet retentive of a sufficient supply of liquid. It should be soft, cheap, and readily cleansed or renewed. Sponge has been the favorite of late, owing to the superior softness and water-absorbing power possessed by it in contrast with wash-leather or muslin. It has the disadvantage, however, of excessive humidity — often drenching contiguous clothing; added thickness, leading to increased resistance and alterations of resistance while *in situ*, when the pressure is slightly changed; irregularity of surface, causing pain at first instant of contact, and a subsequent unequal distribution of current through the area covered by the electrode. In addition, these sponges, unless frequently removed, cleansed, and carefully re-sewn, soon become unfit for use from an accumulation of verdigris, saline deposits, epidermic scales, and sebaceous matter. Their instrumentality in the transference of disease from patient to patient can readily be conceived, and, unfortunately, instances of this unpardonable accident are on record.

With these disadvantages in mind, the substitution of absorbent cotton as a covering recently occurred to me. A trial demonstrated its value, and I immediately removed the sponges from the greater number of my electrodes. It is applied to the brass disk in a few seconds, after the manner of gynecologists when covering their uterine applicators: a pinch of sufficient size, and with the proper smoothness of fibre, is laid on the face of the disk and the edges pressed over and twisted around the shank by a twirling motion of the electrode. In a moment it is ready for use; and the covering may be rejected immediately after the application. But little practice is required to learn how much cotton to use, and to obtain a smooth covering on any but the very

largest disks. The many advantages of this material for this purpose are too apparent to require mention, not the least being its preëminent smoothness, softness, and neatness.

MEDICAL PROGRESS.

A New and Certain Diagnostic Sign of Pregnancy in the First Month.—Reinl, in the *Prager med. Wochenschrift*, No. 26, 1884, claims the following to be a certain indication of existing pregnancy, as early as the first month. A condition of unusual softness, elasticity, and thinness of the lower uterine segment—that is, the segment immediately above the insertion of the sacro-uterine ligament. The cause of this condition is explained by the fact that the lower uterine segment, as the thinnest part of the whole organ throughout pregnancy, must be exceedingly thin, succulent, and elastic.

Absence of this condition does not, however, contraindicate the existence of pregnancy.—*Centralblatt für Gynäkologie*, December 27, 1884.

Extirpation of a Laryngeal Polypus after Local Anæsthesia by Cocaine.—Dr. S. Meyerson, of Warsaw, publishes in the *Wiener med. Presse*, Dec. 28, 1884, an interesting case of the removal of a laryngeal polypus after the local application of cocaine, which still further confirms the value of this drug in all operations connected with mucous membranes.

The patient, a man forty years of age, had suffered for five years from hoarseness. For a short time previous the hoarseness had increased, and when he was first seen by Dr. Meyerson, he was entirely voiceless. Examination revealed the presence of a granular pharyngitis. The uvula was much thickened and lengthened. The laryngoscopic examination was very painful. In the larynx under the edge of the right vocal cord, about one-twelfth of an inch from its anterior extremity, was present a pear-shaped polypus about two-fifths of an inch long, attached by a slender pedicle. It changed its position, both in inspiration and expiration. During inspiration, the polypus was drawn beneath the vocal cords into the larynx; and in expiration, it was drawn outside the larynx, and, resting upon the vocal cords, covered them to an extent of two-thirds their length. During phonation, the polypus was held between the vocal bands and was pressed upon by them, their edges being separated about one-twelfth of an inch. The introduction of the instruments into the larynx excited considerable reflex spasm, and a sixteen per cent. solution of cocaine was applied to the uvula, soft palate, pharynx, base of the tongue, and larynx. Within two minutes the polypus was extracted without reflex spasm, and the patient's voice was restored; he was, however, somewhat hoarse, owing to the thickening of the right vocal cord.

Perineal Calculus.—Dr. Sarget, in the *Union de les Ciencias Médical* et *El Siglo Médico* of Nov. 1884, reports an interesting case of perineal calculus in a laborer who for two years had had a swelling in the perineal region, which caused great inconvenience in urination. The patient was a man of fifty years, had fever with nocturnal exacerbations; the tongue was dry and furred; there were anorexia, polydipsia, almost continual suborbital headache, and sleep was incessantly disturbed by frightful nightmares. Various physicians had examined the growth, some pronouncing it to be a malignant tumor of the prostate, and others an inflammation. Examination revealed an induration extending from the root of the scrotum to the sphincter ani of a nearly cartilaginous consistency, contact with which, however light, caused extreme pain. Urination was extremely painful and accomplished drop by drop. The patient would not permit the introduction of a bougie; accordingly treatment was only tentative, rectal examination having only been made and no definite conclusion reached. Bromide and belladonna were given internally and an emollient ointment externally. Under this treatment the tumor diminished somewhat, and it was continued six days. At the end of this time the patient returned, complaining of insupportable pain. Application of a strongly iodized ointment increased the pain, and was discontinued. Examination now showed a point of fluctuation, and puncture permitted the escape of great quantities of pus, and on introducing the finger a foreign body was felt at considerable depth in the tissues. It was rough, hard, and could not be moved. The day following, the incision was enlarged, and the body removed in three pieces. The wound cicatrized slowly, but both the fever and difficulty of micturition at once disappeared, and there was great improvement in health.

The patient gave a history of having received a long time previously a contusion of the perineum, following which there was retention of urine for thirty-six hours and great pain for fifteen hours. The pain had gradually disappeared, but some difficulty in urination had ever since persisted. These facts make it probable that there had been infiltration of urine and a consequent precipitation of urinary salts, to which the calculus was due. Examination of the calculus, which was of the size of a very large kidney bean, showed it to consist of the phosphate and carbonate of lime and some organic matter, no trace of the urate of lime being present.—*Gazette Hebdomadaire des Sci. Méd. de Montpellier*, Jan. 3, 1885.

Anuria and its Treatment.—Dr. Mandrillon, in the *Journal de Médecine de Bordeaux*, after discussing anuria in its various phases, reaches the following practical conclusions:

1. Anuria is only a symptom, having for its causes (apart from a nervous or hysterical origin) a simple mechanical or organic obliteration of the ureters, or some disease of the kidneys.

2. Anuria is serious only on account of the uræmia which it causes.

3. Its gravity is in proportion to the lesions produced: fatal, if they are permanent; curable, if they are transient.

4. Anuria which is cured is immediately followed by abundant diuresis of short duration.

The first indication is to bring on urination, and to prevent the accumulation in the blood of waste products; the second is to combat the effects of uræmia. To fulfil the first, the patient should at once be put on an exclusively milk diet. Milk has no diuretic proper-

ties, but taken in large quantities, it raises the pressure in the bloodvessels, and thus favors diuresis, and also reduces to a minimum the production of uræmic products.

Certain drugs, such as digitalis, opium and its alkaloids, and squills, should be prescribed with great caution, inasmuch as they are excreted by the kidneys, and retained, may produce toxic effects.

Chloral hydrate, of all the hypnotics, should be preferred, since it is eliminated in great part by the pulmonary mucous membrane. Alcoholic and diffusible stimulants, and, above all, caffeine are indicated in certain cases to raise without danger the arterial tension.

To combat the accidents of uræmia, two indications present themselves:

1. To prevent as much as possible the formation of urea and uric acid.

2. To expel from the system these poisonous products.

To this end the hot bath is prescribed, and highly recommended as giving excellent results. This should be supplemented by drastic purgatives and emetics as additional means of removing the retained waste products, which, if allowed to remain, cause uræmia.—*Revue Médical*, Jan. 2, 1885.

PEROSMIC ACID IN PERIPHERAL NEURALGIA.—NEUBER has lately called attention to the value of perosmic acid in peripheral neuralgia. The remedy seems also worthy of trial in sciatica, as is shown by its use in numerous cases treated by DR. ANTON WÖLFLER. The first case cited is that of a man who for three years had suffered from sciatica, the affection finally becoming so painful as to prevent all labor.

Oct. 9: an injection of one-half a Pravaz syringeful of a one per cent. solution was first administered, between the trochanter and the tuber ischii. A whole syringeful was afterwards employed.

Oct. 10: two injections were administered. At first severe pain was felt in the region of the peroneal nerve, but soon the neighboring parts were entirely devoid of sensation, the whole leg feeling "as if it were wood."

Oct. 12: third injection. The neuralgia has lost its intensity. The patient himself designated the point for the injection. During the injection severe pain was experienced in the region supplied by the peroneal nerve.

Oct. 13: The pains were comparatively unimportant, however not entirely abolished. The toes were slightly movable. Pain in the region of the peroneus muscles, and injection was made there.

Oct. 14: All pain has markedly abated. In the leg none at all was felt. Injections were nevertheless made on the 16th, 22d, 23d, 26th of October. On the last day, the patient declared himself free from pain, and that he needed no more injections. Four months later, the patient ceased to be under observation. The pains at this time had not returned, and the man was able to go long distances on foot without inconvenience or pain. In other cases, the use of the acid hypodermically was followed by like favorable results. As to its beneficial effect in trigeminal neuralgia, nothing as yet can be said. The cases in which it has been applied are not sufficiently numerous and the time of observation too short.

The assertion that the hypodermic injection of perosmic acid is painless is incorrect. Every patient in whom it was used complained of pain, which lasted at least from one to two minutes. It is further of interest that several of the patients designated the direction of the pain, which corresponded to the course of the nerve and its branches, and that the first sign of improvement was that they no longer could distinguish whence their former pain started or to what region it extended.

Although the value of the acid for peripheral neuralgia is not certainly established, the means for successfully treating this affection are so meagre and unsatisfactory that it is certainly worthy of further trial, even if it is not found to give relief in every case. It seems that it is more beneficial in some localities than in others, for instance, in the sciatic than in the trigeminal regions.—*Wien. med. Wochenschr.*, Dec. 14, 1884.

A HERMAPHRODITE.—M. GÉRIN-ROSE, at a recent meeting of the Société Médicale des Hôpitaux, presented a cast of the genital organs of a hermaphrodite (*sans exces masculin*). Classification of Geoffroy Saint-Hilaire.

Julie D., aged 26, entered the hospital ill with typhoid fever. She had the features and appearance of a woman, voice, breasts, etc. The labia majora and minora were normal, but the clitoris was of the form and size of a small penis. Examination showed a glans penis, prepuce, and corpora cavernosa. The glans was imperforate. The meatus urinarius was beneath the penis. There were no traces of a hymen nor of carunculæ myrtiformes. She was not a virgin, as her history affirms. A vaginal orifice opened directly from the vulva without an intermediary diaphragm. There was a cul-de-sac at the extremity of the vagina, but no uterus. The woman had never had menstrual periods nor uterine congestion. There were present two ovoid bodies in the labia majora resembling testicles. The probable absence of ovaries and the presence of testicles is a proof that Julie was a man, although she presented the external characteristics of a woman. She, however, cared nothing for men. The "vagina" only, was sensitive. Friction of the penis (or clitoris), though causing erection, produced no other effect.—*Archives de Tocologie*, Jan. 1885.

DISLOCATION OF THE HIP; SUCCESSFUL REDUCTION AFTER TWELVE WEEKS.—Drs. J. H. and L. T. Hall, of Potosi, Mo., report a case of successful reduction of a dislocated hip twelve weeks after injury. The patient, a little girl, fell from a tree and dislocated the hip. The luxation was promptly reduced under chloroform, but spontaneous dislocation seems to have at once occurred. Twelve weeks after the injury the Drs. Hall were called to see the patient, and having etherized her again reduced the luxation which was backward, the head of the femur resting on the dorsum of the ilium. Extension was applied, and four weeks later the child was able to use the leg freely. Considering the length of time intervening between luxation and its reduction, the case is unusual.—*St. Louis Courier of Medicine*, January, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

PHILADELPHIA.

SATURDAY, FEBRUARY 7, 1885.

INTUSSUSCEPTION AND ITS TREATMENT.

OF the affections of the intestines, there is not one of more importance than obstruction. From whatever cause it may arise, the symptoms are usually severe, the mortality is exceedingly high, and the treatment has, up to the present, been by no means satisfactory. Hence it is that we welcome with no little pleasure the interesting and instructive lectures on "Acute Intestinal Strangulation and Chronic Intestinal Obstruction," delivered by MR. BRYANT before the Harveian Society of London, and published in the *British Medical Journal* for November 22 and 29 and December 13, 1884, and the recent paper on the "Treatment of Intussusception," read by MR. TREVES before the Medical Society of London, and published in the same periodical for January 3, 1885. As the entire subject of obstruction of the intestines is too comprehensive for discussion in these columns, we shall confine our remarks to intussusception, which is one of its most common causes.

Mr. Treves divides intussusception into four kinds, namely, enteric, colic, ileocæcal, and ileocolic. In the enteric variety, which constitutes 30 per cent. of the entire number, the small intestine, and usually the lower part of the jejunum, is alone involved, and the resulting tumor is small. In the colic, which forms 18 per cent. of the whole, the colon is alone implicated, and usually that part to the left of the transverse colon. In the ileocæcal, which comprises 44 per cent. of all cases, the ileum is invaginated into the cæcum; while in the ileocolic, which forms 8 per cent., the ileum is prolapsed through the ileocæcal valve, and the cæcum is invaginated into the colon. The colic variety is, as a rule, chronic, and the other varieties pursue an acute or subacute course.

From a clinical standpoint, Mr. Treves separates intussusception into four classes: First, the ultra-acute, in which death follows within twenty-four hours; secondly, the acute, lasting from two to seven days; thirdly, the subacute, which terminates fatally between seven and thirty days; and, fourthly, the chronic, in which the period is extended beyond thirty days. The ultraäcute is very rare. Of the remaining clinical varieties, out of every 100 cases, 48 will be acute, 34 subacute, and 18 chronic. The acute varieties are most common in children, while chronic cases are most frequent between the ages of twenty and forty.

In the treatment of intussusception, the question of spontaneous recovery after sloughing of the invaginated gut has had an important influence upon the conduct of not a few surgeons, who have permitted nature to pursue an unaided course in preference to resorting to laparotomy. Spontaneous elimination of the gangrenous intestine occurs in about 42 per cent. of all cases; but it is less common in the most frequent form of the lesion than in the other varieties, being about 20 per cent. for the ileocæcal, 28 per cent. for the colic, and 61 per cent. for the enteric. It is most rare, moreover, in children under the age of eleven years, in whom intussusception is most common, and its mortality is over 40 per cent., being relatively higher at the very ages when spontaneous elimination is most frequent. Hence, although three-fifths of the cases, and many of them of the gravest character, recover after sloughing of the invaginated bowel, this termination holds out delusive hopes, and it may be safely said that in children under eleven years, who constitute 50 per cent. of all forms of invagination, not more than twelve out of every hundred will be the subjects of spontaneous cure.

From these considerations, Mr. Treves deduces the axiom to place no reliance upon expectant measures, but to treat the case promptly and actively. Of remedial agents, opium stands at the head of the list. It places the bowel in a state of physiological rest, checks pain, relieves shock, prevents the increase in the size of the invagination, although the process of strangulation may still progress, and places the patient in the most favorable position for the employment of further treatment. No nourishment should be given by the mouth in acute cases, as food is rejected almost as soon as it is swallowed, while thirst may be relieved by enemata or by sucking ice.

With a view to the reduction of the invagination, injections of water, at a temperature of 99° F., should be resorted to as soon as the patient is under the influence of opium, but no benefit can be expected to attend their use in acute cases after the second day.

In subacute cases, on the other hand, successful reduction has followed the employment of enemata at almost any period of the disease, even after the lapse of twenty days. Massage, electricity, the use of metallic mercury, ice, and other modes of treatment are useless, frequently harmful, and waste precious time. Hence, should enemata and opium fail, laparotomy is indicated in all acute and subacute cases within the first forty-eight hours, and, if possible, within the first twenty-four hours when the patient is an infant or young child.

The procedure should be conducted with strict antiseptic precautions, and the median incision is preferable, as it permits exploration of the entire area of the abdomen. When the state of the gut warrants it, gentle attempts should be made to reduce the invagination; but should the reduction be difficult or impossible, or should the bowel be severely damaged, or partially or wholly gangrenous, the involved parts should be resected, and an artificial anus be established. The practice of uniting the divided ends of the bowel immediately after the resection is to be condemned; but the artificial anus may subsequently be cured by the ordinary resection operation.

The mortality of laparotomy is 72.7 per cent. as estimated from 33 recorded cases; where the reduction was easy, it was only 30 per cent., while it was 91.3 per cent. where it was difficult or impossible. If in the future the operation be performed early, there is every reason to believe that the fatality will be much less.

Having drawn attention to the principal points discussed by Mr. Treves, it only remains for us to say that we think that the rules of practice which he has laid down are correct, and that they will be approved by the majority of surgeons. Mr. Bryant, indeed, goes still further, since he advises that laparotomy, with the formation of an artificial anus, should be performed in all cases of acute intussusception as soon as the diagnosis is made, and in all cases of chronic invagination which have not been relieved by other measures within three or four days.

PRECOCIOUS MATURITY.

WHILE it has been proved that race, climate, mode of life, and heredity are important factors in determining the time of the first menstruation, that, which has been called by Raciborski the genital sense, may have a greater power than all of these. This genital power varies in individuals, and hence we find a difference in individuals living in the same climate, and apparently surrounded by the same circumstances and under the same influences, as to the time when the first menstrual flow occurs. The great energy of the genital sense explains, too, the advent of menstruation in those who, so far as their age is concerned, are mere children, or even infants. Examples of these "emmenic monstrosities" are occasionally reported in medical journals, and recently DR. V. GAUTIER has collected, in the *Journal D'Accouchements*, forty-one instances of what is called precocious maturity, and presents some interesting facts in regard to them.

In about one-half the cases menstruation appeared in the first year; adding to these those in which menstruation occurred in the second year, the number first menstruating within two years becomes more than one-half. Dr. Gautier justly observes that menstruation within the first two years is so striking a fact, that all cases of this kind are published, while with each added year the occurrence is not so remarkable, and hence the cases are not so generally reported. He believes that, while examples of menstruation at seven or eight years have been published, he is the first to record a case of menstruation between five and six years.

One of the most interesting cases the author has given is that of a girl dying at three years and a half from a hematocele, an external flow having been impossible because of genital atresia.

Those who have met with cases of precocious menstruation—we have seen a girl who menstruated at three years and a half—have observed that the menstruation is but a part of the evidence of early puberty. These emmenic monstrosities have a physical development far beyond their years, or, as it may be, months; their weight is four or five times greater than that belonging to their age, and the pelvis and the mammary glands have undergone a precocious development. The exception to this rule is furnished by infants who have a hemorrhage from the sexual organs at birth, which returns with more or less regularity: in these cases no similar development has been seen.

It is very natural and very common for mothers to be anxious in regard to children manifesting the signs of precocious maturity: this is especially true if the puberty is shown by menstruation. The family physician will usually be applied to for some means to stop the periodical flow. Of course, however, he will recognize the wisdom of non-interference, carefully abstaining from remedies to check a physiological discharge, and directing his attention to the child's general health.

TOXIC PROPERTIES OF NORMAL URINE.

THAT normal urine is possessed of toxic properties has been affirmed and denied by various observers. The former opinion, however, has most supporters, and efforts have been made to identify the toxic substance which at one time has been said to be urea, and at others uric acid, creatin, and the salts of potassium.

The subject has been investigated by GAUTIER, POUCHET, BROUARDEL, BOUTMY, and others, who discovered and studied the substance known as ptomaine, which, on account of its behavior, was regarded as an alkaloid—the alkaloid of putrefaction.

Recently, however, M. BOUCHARD, in a communication to the Société de Biologie, of which a résumé is published in *Le Progrès Médicale*, Dec. 20, 1884, has treated the subject anew. He concludes that there exist alkaloids in the normal state of the living organism and are formed in the digestive tract, where they are elaborated by vegetable organisms which are the agents of putrefaction. The alkaloids of the normal urine represent a part of the alkaloids of the intestine, whence they are absorbed, and excreted by the kidneys.

Before proceeding to study the toxic substance itself, Bouchard investigated its effect upon animals by the intravenous injection of urine. He thus ascertained that from fifteen to twenty drops of urine, either in its natural state or neutralized, were sufficient to kill a frog, and that, in the dog, by the injection of a sufficient quantity, there were produced contraction of the pupil, diminution in the number of respirations, feebleness of muscular movement, lowering of temperature, abolition of reflex movements, and a state of torpor, soon succeeded by death from arrest of respiration, the heart continuing to beat for some time. The effects vary in intensity with the quantity injected, and when the animal recovers, muscular feebleness continues until the functions are reëstablished apparently by an abundant secretion of urine. These symptoms at least suggest those of uræmia.

The observer then sought to determine the elements in which the toxic influences reside. Urea and uric acid were both shown to be innocuous, while the salts of potassium exist in too small proportion to be harmful. On the other hand, there was reason to believe that some toxic properties do reside in the coloring matters of the urine, since urine filtered through animal charcoal was found to be less toxic in its effects than unfiltered urine, while such effects were not totally removed. That the poisonous properties are not due to volatile substances, is proved by the fact that ebullition does not destroy them, and that they persist in the extracts of urine as well as in the natural liquid, and especially in the alcoholic extract, which does not, however, produce contraction of the pupil but salivation in its stead. This same alkaloid, the alcoholic extract of which produces salivation, is found also in the liver, in muscle, and in blood. Finally, if the residue left after extraction with alcohol be redissolved with water, and the solution thus obtained be injected into the veins, the phenomena are much more serious than when the alcoholic extract itself is injected.

These toxic effects of urine are found to be increased even by a simple cold, or feeling of lassitude, as well as by more serious acute maladies, showing the extreme importance of a knowledge of the substances producing them, since one may ultimately expect therapeutics to be influenced by such information.

As the result of these observations, Bouchard has concluded that toxic influences reside not in a single one, but in several of the constituent elements of the urine, none of which, however, except the coloring matters, has been definitely ascertained. Doubtless further accurate chemical researches will shortly add to our knowledge of these matters.

TARNIER'S BASIOTRIBE.

A RECENT number of *Le Progrès Médicale* contains a communication made to the Copenhagen Congress by Dr. PAUL BAR upon the mode of employing Tarnier's basiotribe, and the results obtained by it, As our readers doubtless know, this recent invention of the distinguished Paris obstetrician consists of three branches, two of these being similar to the blades of the cephalotribe, and similarly connected by a compressing-screw, while the third is a perforator. The instrument happily unites the advantages of the cranioclast and of the cephalotribe. As illustrating the value of the instrument, Dr. Bar narrates a case in which delivery was successfully effected by it, though the antero-posterior diameter of the inlet was only two inches and three-tenths.

The combination of a perforator with an extractor, and an extractor that grasps so firmly that it cannot slip, certainly presents obvious advantages. Tarnier's perforator is certainly quite equal to Simpson's basylist, or to Hubert's transforator in breaking the base of the skull, and we should think more easily and safely manipulated than either of the latter. After using the basylist, Simpson employs the cranioclast for extraction, while Hubert, after transforation, united delivery to the uterine contractions, or aided them by slight traction. Tarnier's method seems simpler, more rapid, and safer.

A CENTURY OF PUBLISHING.

ON the occasion of the Centennial Anniversary of the foundation of their business house, Lea Brothers & Co. have issued an interesting sketch of its history, which dates back nearly to the birth of the Republic. The business was established by Matthew Carey, who, at the early age of twenty-five, after having attained considerable reputation as a political writer, left his native land, in disguise, at a time when there was a criminal prosecution hanging over him for libel on the Premier, and the Attorney-General had filed a bill to deprive him of the protection of the grand jury. He at once established

in Philadelphia a daily paper, called *The Pennsylvania Evening Herald*, followed shortly after by a monthly magazine, subsequently known as *The American Museum*. The publication of books soon followed upon journalism, and the medical branch of the business took firm root with the establishment, in 1820, of the *Philadelphia Journal of the Medical and Physical Sciences*, which, in 1827, changed its name to *The American Journal of the Medical Sciences*, and which is now, with the single exception of the *Edinburgh Medical Journal*, the oldest existing medical journal in the English language. The Medical News was established by the same house in 1843.

The medical department of the business soon assumed leading proportions, and, finally, upwards of forty years ago the attention of the firm became concentrated on it, and its list of publications contains the books of Wistar, Chapman, Coxe, Horner, Gibson, Dewees, Dunglison, Meigs, Hodge, Gross, and, in addition, of nearly all the prominent medical writers of the present day.

During its long career, the house has been in intimate business relations with the profession in this country, it has supplied it with by far the greater part of its literature, and the works of almost all the leading American medical writers bear its imprint. During the whole of this period, it has invariably maintained its commercial honor, and never failed to meet its obligations to the day, and has enjoyed the entire confidence and esteem of its patrons.

With such an honorable record, the house enters upon the second century of its existence, with all the evidences of undiminished vigor and energy, and with the best wishes of the profession for a long continuance of the prosperity which has marked its past career.

"FURTHER WEST."

Dr. Skene Keith, son of the great ovariotomist, in discussing before the Edinburgh Obstetrical Society Emmet's operation for tears of the neck of the womb, stated that "when he returned from America he had too sanguine ideas of the value of the operation, and was eager to perform it on all possible cases. Since then he had modified his views; and even by Emmet himself the operation was now one which was comparatively seldom performed. Those who most frequently performed it were chiefly the men further west."

Dr. Keith, whose visit to this country a year ago is remembered with pleasure by the members of the profession who met him, is probably mistaken in his statement as to those who chiefly perform the operation in question being "further west." Both east and west, in some localities, there may be found men who attach too great value to the operation, and are unwilling to listen to the conservative teaching of Dr. Emmet himself, and to follow his advice. But we do not believe that such men are more numerous in one than in another part of our country. Light and darkness belong not to places so much as to men, and in this country of magnificent distances, but of easy communication, and a country with a universally pervading periodical literature, knowledge and professional skill are not bounded by geographical lines, or determined by the number of miles a man lives from the seaboard.

REVIEWS.

The Formation of Poisons by Micro-organisms. A Biological Study of the Germ Theory of Disease. By G. V. Black, M.D., D.D.S. Pp. 178. Philadelphia: P. Blakiston, Son & Co., 1884.

The second portion of this volume, for which alone the author claims originality, professes to supply the *why* of many experimental facts furnished by such mere routine observers as Koch and Pasteur, and when sifted, as the author suggests, is found to contain some good grains among the chaff—a faint praise to which many more pretentious works are less fairly entitled. After a fair account of the rise and progress of the germ theory, in the first part of the book, Dr. Black starts, in his second section, with the statement that the mere presence of the organisms is not a sufficient cause for the diseases which experiment teaches us are produced by them, and endeavors to show that the phenomena of the contagious diseases are in many cases best explained by the supposition that during the growth of their severally characteristic bacteria, ferments somewhat analogous to ptyalin, pepsin, etc., are formed, and act as local or general poisons upon the animal system in which their development occurs. This doctrine, as is pointed out, fully accords with what we know of the life history of the *Torula cerevisiæ* or yeast plant, during the development of which, sugar is split up into alcohol and acetic acid, as well as of many similar fungoid growths. It also gains support from the curious experiment of Sachs, proving the power of plant roots to corrode, and, as it were, digest the surface of a polished marble plate, upon which they ramify. A well-sustained effort is made to compare this operation with the resorptive digestion in an animal body, by which a clot of blood, a catgut ligature, the fang of a temporary tooth, or a fragment of necrosed bone is removed. Finally, the violent symptoms of many acute infectious diseases in their more virulent forms are attributed to the rapid development of poisons similar to the vegetable alkaloids, to the ptomaines, or to Bergman's sepsin, produced by particular bacteria, which "remoleculize" the normal fluids into compounds noxious to life. Such a theory as this admirably explains the phenomena presented in rapidly fatal cases of cholera, in which death takes place before time for a general distribution of bacilli throughout the economy in dangerous abundance is allowed. It also gives a clue to the mechanism of speedy death induced in mice by injections of the contents of the intestines of cholera patients from which the bacilli had been removed. In an appendix, Dr. Black ably argues in

favor of the hypothesis that dental caries is the result of various corrosive materials elaborated in the mouth during the process of fungoid growth, substantially as urged by Leber and Rottenstein in 1868.

This really useful book is marred by evidences of imperfect scholarship. Thus, for example, the well-known treatise, "*De re rusticâ*," of Varro (not that of Cato), is cited on page 14 as if it were the name of some author of antiquity, and by way of rendering the blunder more ludicrous, has the constituent words of its title connected by hyphens, in a manner which would have sadly shocked the sensibilities of the erudite old Roman.

SOCIETY PROCEEDINGS.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

Seventy-ninth Annual Meeting, held in Albany, February 3, 4, and 5, 1885.

(*By Telegraph from our Special Reporter.*)

TUESDAY, FEBRUARY 3D—FIRST DAY.

MORNING SESSION.

THE Seventy-ninth Annual Meeting was held in Agricultural and Geological Hall, and the Society was called to order at 10 A.M. THE PRESIDENT, DR. B. F. SHERMAN, of Ogdensburgh, in the Chair.

The session was opened with prayer by Rev. Dr. Reese.

THE PRESIDENT then delivered his

INAUGURAL ADDRESS.

He said: Gentlemen, in behalf of the Medical Society of the State of New York, I welcome you to this, its seventy-ninth annual session.

I recognize before me many familiar faces, also some new ones, and am sorry to see that some of our former friends and co-workers are conspicuous by their absence; but earnestly hope and believe that, after a sober second thought, our brothers will return to the old home, the doors of which shall always be open to receive all the honest workers in science and searchers for the truth.

We live in an age of wonderful improvements, and our profession in all its branches has kept fully abreast with the age. One of its latest gifts to suffering humanity is the new anæsthetic, cocaine, which promises in its relief of pain and suffering to be second to ether and chloroform, and to simplify many important, as well as minor, surgical operations. To make this Society what it should be, demands an earnest effort on the part of us all, and perhaps some change in the programme. We should have a better room in which to hold our meetings, one with better acoustic properties as well as better ventilation. Too many members and delegates come here to serve two masters—to represent their county societies in this meeting, and at the same time to represent their local Masonic lodges in the Masonic convention, or to see and study the white elephants of the city. We should have a less number of papers and devote more time to the discussion of the few. We should at once memorialize Congress to furnish a fireproof building for the preservation of the National Medical Library and Museum. I would respectfully advise the amendment of article 2, section 2, of the by-laws, in a way as to require but one Address from the President, and that on the opening of the first day's session.

He presented a communication from the New Jersey Medical Society in regard to a prescribed preparatory curriculum, and suggested its reference to a special committee, to report at the next annual meeting.

The following committees were then appointed:

Business Committee.—Drs. J. V. Kendall, of Baldwinsville; Laurence Johnson, of New York; and L. E. Felton, of Potsdam.

Committee on the President's Address.—Drs. W. W. Potter, of Buffalo; T. H. Squire, of Elmira; and A. M. Phelps, of Chateaugay.

COMMUNICATIONS FROM COUNTY MEDICAL SOCIETIES

were then called for.

The Erie County Medical Society presented the following:

At the annual meeting of the Erie County Medical Society, held January 13, 1885, the following resolutions were unanimously adopted:

Whereas, The Medical Society of the County of Erie has, during the year last past, frequently placed upon record its appreciation of the importance of the matter of State license of practitioners of medicine, and

Whereas, This subject is receiving the earnest attention of the medical profession of the State as represented by the Medical Society of the State of New York, therefore

Resolved, That this Society would respectfully represent to the Medical Society of the State of New York, its confirmed sense and conviction of the importance of securing to the profession and the public the advantages of a State licensing board.

Resolved, That it is the further sense of this Society that such State licensing board should be composed of men having no connection with any medical institutions liable to conflict with the full and unbiassed discharge of their duty as State examiners.

The New York County Medical Society presented a number of biographical sketches; also some suggestions in reference to business, and some resolutions in regard to the By-Laws, which were referred to the Committee on the By-Laws.

DR. HENRY I. BOWDITCH, of Boston, an honorary member of the Society, was introduced and invited to a seat on the platform.

DR. W. W. POTTER, of Buffalo, read a paper entitled

A CASE OF ACUTE PELVIC ABSCESS, WITH REMARKS.

The case related was of a woman 38 years old, who was seized with pain in the right iliac region, without preceding illness, and ten days afterwards the reporter drew off, by aspiration through the vagina, nearly or quite two quarts of fetid pus. A drainage-tube was inserted after enlarging the opening, and the cavity washed out with mercuric chloride water, 1 to 3000. The symptoms of septic absorption were marked, and, two days after the operation, the patient was thought to be dying. She rallied, however, under hypodermatic injections of brandy, ether, and alcohol, and made a good recovery at the end of six weeks. Iodoform was injected into the pus cavity in the form of an emulsion, and this was believed to play an important part in the

successful issue, for, in one week after commencing its use, the pus cavity closed by granulation, and the drainage-tube was no longer required. The interesting points which the case presented were:

1. The rapidity with which so large an abscess formed in the non-puerperal woman.

2. The large quantity of pus which accumulated in so short a time, and which was drawn off at a single sitting.

3. The corresponding rapidity with which the cavity filled by granulation, and finally closed.

4. The introduction of iodoform by emulsion into the cavity, and the rapid improvement which seemed due to its use.

The pathology of non-puerperal pelvic abscess was briefly considered, and its surgical treatment dwelt upon at some length. The treatment by evacuation was regarded as the only safe method. This could be done through the vagina if the abscess was within easy reach —*i. e.*, well down in the pelvic cavity; but, if high up, and hard pressure in the posterior vaginal cul-de-sac, or vault, were required to reach it, then the method of Tait was advocated. This consists, essentially, in opening the abdomen down upon the tumor, stitching the abscess sac to the margins of the incision, laying it open freely, cleansing it antiseptically, and inserting a drainage-tube.

Byford's plan of curetting the walls of chronic abscesses for the removal of tag-like formations was commended as both useful and scientific, in cases in which these pathological formations are found to consist.

The improved methods of diagnosis in pelvic diseases were referred to, viz.: The Sims's position, bimanual palpation, and the aspirator; and the corresponding improvement in the surgical care of these cases since antiseptics have come into vogue, was remarked upon.

Particular stress was laid upon the necessity for the complete evacuation, and thorough cleansing of the abscess sac at the first sitting, as well as the frequent and careful washing out of it subsequently; all of which must receive the personal attention of the surgeon, for he alone is familiar with the topography of the abscess and its surroundings.

Dr. Mundé, of New York, could not help believing, from the history of the case, that the abscess must have been due to one of two things, either a hematocele accumulating and becoming rapidly septic, or the result of septic material being carried into the pelvic cavity from salpingitis, or through the Fallopian tube. The general character indicated that the inflammation had not been in the connective tissue. If such had been the case, he could not see how so large an abscess could form in the connective tissue in so short a time.

He thought that it would have been better to have avoided the use of the lancet and have enlarged the opening by stretching. He considered a 1 to 3000 a rather strong solution of corrosive sublimate, to be used so often as is necessary in these cases. He would begin with 1 to 1000, and reduce to 1 to 5000, and would use this every half hour. In using the drainage-tube he had secured it in some instances to the cervix with a silver wire. His recent studies had led him to believe that the most common cause of these abscesses, as well as of local peritonitis, was salpingitis, and that through the Fallopian tube, which furnishes communication between the exterior and the peritoneal cavity, septic material passes.

In regard to treatment, he did not consider opening into the vagina the best in all cases. If the abscess is large and points in the vagina, such an operation is proper, but in many of these cases the abscess does not so point, and this especially is the case in abscess in the cellular tissue. In the large majority of cases he thought that the best plan would be to open the peritoneal cavity and evacuate the abscess. If it involves the tube and ovary and is small, the whole mass may be removed together and a drainage-tube be put in. If the abscess is large and fetid, and there is danger of septic infection, there would be no objection to cutting down and making a counter-opening in Douglas's cul-de-sac. In many of these cases even if the abscess is evacuated through the vagina, drainage will have to be continued almost indefinitely, for the original trouble, the inflammation of the Fallopian tube, is left behind.

Dr. Ely, of Rochester, reported a case of pelvic abscess treated in a manner somewhat different from the case of Dr. Potter. This was a case of latent abscess, the patient presenting no symptoms of pelvic trouble, but seeking advice only for a general ill-health and latent suppuration. It was in an unmarried girl of sixteen. Attention being attracted to the abdominal region, examination revealed a tumor which simulated pregnancy. Examination per vaginam, however, showed a small uterus, and suspicion of an abscess was aroused. There was no pointing in the vagina. Dr. Moore, of Rochester, saw the case, and concurred in the diagnosis of a collection of pus. A large curved trocar was introduced below the navel and carried through into Douglas's pouch. The removal of the trocar was followed by the escape of three pints of fetid pus. A drainage-tube was inserted, one extremity projecting from the abdominal wound and the other into the vagina. The abscess cavity was washed frequently with warm water. The result was rapid closure of the abscess and complete recovery of the patient.

Dr. Bowditch, of Boston, described a case illustrating the advantages of abdominal section. A child, two years of age, was seen in consultation in a condition of apparent articulo mortis, suffering with an abscess within the abdominal cavity. The abdomen was punctured and a large amount of pus escaped. Three days later the pus had reaccumulated. The incision was then made into the abdomen, and the peritoneal cavity was thoroughly washed out. Complete recovery followed in a short time. He thought that surgeons were too much afraid of opening the peritoneal cavity, and in his opinion no one should ever be allowed to die where there was a chance of benefit from this operation.

Dr. Baker called attention to the method recommended by Dr. Emmet in the early treatment of pelvic inflammation—*i. e.*, the continuous use of water so hot that the external parts have to be protected. This treatment will abort many cases if begun early.

Dr. Potter, in closing the discussion, said that he had not been able to give all the details in the limited time permitted to him. In regard to causation, the question of retained products of conception was considered, but rejected. Hematocele was considered, but when first examined there was no immobility of the

pelvic organ, and nothing to indicate that the abdominal cavity was involved. In regard to the use of the knife, he had no means of dilatation, and as the opening was in the central line, he considered it safe to use the lancet. Under any other circumstance, he should avoid the knife.

DR. DAVID WEBSTER, of New York, then read a paper on

JEQUIRITY AS A REMEDY FOR GRANULATED LIDS WITH PANNUS.

He opened with a reference to the number of chronic cases which must be treated by the general practitioner, and he thought that jequirity, if used with proper care, could be employed by the general practitioner, if the following rules be observed:

1. Use the drug only in cases in which considerable pannus exists.

2. Use nothing stronger than a one-fourth of one per cent. solution.

3. Make the application only once a day, and do not repeat it after the characteristic inflammatory reaction begins to show itself.

A solution of the proper strength may be made by mixing an average-sized bean in one ounce of water. This should be allowed to stand for four hours and then filtered. After being kept a week, the solution becomes worthless. The solution should be thoroughly applied over the eyelids and the patient allowed to bathe the eye with it for about five minutes. One application is generally sufficient, although it sometimes has to be repeated. In a day or two, the conjunctiva is covered with a thin membrane. The inflammation subsides after a few days, and the granulations and pannus will be found to have disappeared. If the cure is imperfect, the application may be repeated in the course of a month.

DR. ROOSA, of New York, considered jequirity a valuable remedy in the intractable cases described.

DR. T. R. POOLEY, of New York, considered jequirity a very dangerous drug. It is of little or no use except in cases in which it is justifiable to resort to extreme and hazardous measures.

The further discussion of Dr. Webster's paper was postponed to allow of the reading of reports from several committees.

THE COMMITTEE ON LEGISLATION

reported that they had found that a bill to incorporate the Hydro-therapeutic Institute of New York had been simply a measure to revitalize the United States Medical College. This measure was defeated.

A bill legalizing the graduates of the United States Medical College and the College of Physicians and Surgeons, of Buffalo, was not objected to, but certain amendments were proposed which were adopted. These were that the bill should apply only to those who graduated in good faith prior to April 25, 1885. A bill to organize the Niagara University was found objectionable in certain particulars, but these having been removed, the bill was allowed to pass.

The bill to establish a College of Midwifery was objectionable in every particular, and was finally defeated.

A curiosity in the way of medical legislation, which had come under the notice of the Committee, was a bill empowering the chiefs of Indian tribes to examine and license persons in their tribes to practise medicine. This bill was passed unrecognized by its opponents, and it had been impossible to convince the Governor of the necessity of vetoing it.

The Committee suggested an amendment to the laws of 1813, which limited the amount of real or personal estate which a county medical society may hold, the amendment to read: It shall be made lawful for any medical society to purchase and hold any real or personal estate for the use of said society, provided that such real or personal estate shall not exceed $50,000, and further provided that no member be assessed more than five dollars in any one year.

A motion was made to adopt the recommendation in regard to

THE AMENDMENT OF THE LAW OF 1813.

DR. JACOBI, of New York, thought that it was not wise to limit a large society to the same sum as a small society, and suggested that a certain amount, say one dollar per member, would be better.

DR. PIFFARD, of New York, considered that this would have an injurious effect on the bill, as partaking of discriminative legislation.

DR. STURGIS, of New York, moved to amend so as to allow the New York County Medical Society to hold property to the amount of $100,000. Adopted.

The resolution, as amended, was adopted.

The report of the Special Committee on the

BILL TO ESTABLISH A STATE BOARD OF MEDICAL EXAMINERS

was then presented.

The Committee recommended a bill, of which the following abstract was given: It provides for two boards of medical examiners, one for the northern and one for the southern part of the State. Each board is to consist of six persons. They shall hold office for one year only, and shall not be eligible to reëlection within three years. Four subjects were to be examined on, viz.: Medicine, Surgery, Midwifery, and Therapeutics; one examiner in each of the first three named branches, three examiners in therapeutics. Each candidate may choose which of the examiners in therapeutics he will appear before. Two members of the board must be members of the Medical Society of the State of New York, two must be connected with an incorporated medical college, but not connected with the State Society, and two must not be connected with either. The salary of each examiner shall be one-sixth of the surplus fees of the Board, provided this does not exceed $600, except in the case of the secretary and treasurer, who shall receive extra compensation. The remainder of the bill is intended to carry out these provisions.

DR. PIFFARD moved that the bill be made the special order for the meeting of Tuesday evening.

DR. FOSTER moved to amend, to have the bill printed, furnished to the members, and action be deferred to the next annual meeting. Lost.

Dr. Piffard's motion was then adopted.

It was resolved to have the bill printed at once and distributed.

The discussion of Dr. Webster's paper on

JEQUIRITY IN THE TREATMENT OF GRANULATED LIDS

was resumed.

Dr. Knapp, of New York, said that the jequirity treatment had in some cases produced excellent result. It was used at first in many cases, but soon disastrous results were reported, and its circle of indications have gradually become more and more limited, and was now so contracted that its employment should be confined to those desperate cases in which other remedies continued for months had failed. He had at first used it in weak solution, one or two per cent. In the majority of cases, it produced only a mild catarrh, with little influence on the abnormal condition. In five per cent. solution, it produced marked reaction. In some of the cases, there was marked improvement. In other cases, corneal ulcers were the consequence. This had occurred in three cases. In two, the sight was saved, but in the third the cornea sloughed and both eyes were destroyed, The operation of this remedy is to be compared to inoculation with blenorrhagic matter, but it is cleaner and less dangerous. Another remedy which he had used is the so-called peritomy. In a number of cases, this cleared up the pannus, but with it, also, there may be sloughing of the cornea.

Before closing, he referred to a method of treatment of trachoma which he had used largely. This is the old method with sulphate of copper stick. The stick should be perfectly smooth and care be taken to see that the application is thoroughly made to all parts of the affected membrane. The treatment, if persisted in, will give decided improvement in the course of three months,

Dr. Webster did not think that the fact that eyes had been lost after the use of jequirity was a good reason why it should never be used in the desperate cases in which he had recommended it. The same objection might be raised to many other procedures in ophthalmic surgery. Eyes are lost without any treatment, and he had seen them lost under the sulphate of copper treatment.

THE COMMITTEE ON EXPERIMENTAL MEDICINE

reported that no anti-vivisection bill had been presented at the last session of the legislature. They recommended the adoption of the following resolution :

Resolved, That the Medical Society of the State of New York hereby reiterates its conviction that the untrammelled right on the part of medical men to perform experiments on animals is essential to the progress of medicine. Adopted.

The *Committee on Hygiene* made a report which was received and placed on file.

The *Committee on Prize Essays* reported that no essay had been submitted. Received and filed.

Dr. D. B. St. John Roosa, of New York, then presented a paper on

THE REMOVAL OF A CATARACTOUS LENS IN ITS CAPSULE.

If it can safely be performed, he thought that removal of the lens in its capsule would be the best means of removing a senile lens. He suggested an operation which avoids the dangers of the other operations which are generally resorted to. He had performed it in 24 cases. He first inserts a speculum, and, holding the edge with fixation-forceps, then with a Graefe knife a large flap of the cornea is made, and when the section is half completed the back of the knife is turned so as to rest upon the iris, and motion and pressure are made with a view of rupturing the capsule; the lens is forced out by pressure. In some few cases it has been necessary to cut the capsule. Since October last, in every case in which he has attempted it, he has been able to complete the removal of the lens with its capsule. He thinks that cocaine has contributed to the success of the operation. This procedure, he believes, does away with the dangers of the ordinary operation. He does not perform an iridectomy.

Dr. Knapp had performed the old operation, in which iridectomy was not done, some two hundred times, and he thought it was fraught with considerable danger, either at once or in the course of healing. It is possible that the use of cocaine may conduce to the successful performance of the operation without iridectomy; but he thought the results would not be as good as when the iris was nicely excised.

Dr. Webster had seen many of the cases operated on by the method of Dr. Roosa, and he had at first been prejudiced against it, but he was gradually coming to view it more favorably.

Dr. Roosa stated that he had operated on only 24 cases, and that there had been two total failures, which, however, had nothing to do with the lens. The point in the operation is, that there is comparatively no danger of loss of vitreous. Another important point is the fact that no instrument is inserted into the eye after the section is made.

A paper on *The Use and Limitations of Hydrochlorate of Cocaine*, by C. R. Agnew, M.D., was read by title.

Adjourned.

Afternoon Session.

THE NOMINATING COMMITTEE

was announced as follows :

1st District, S. O. Vanderpoel, of New York.
2d District, E. F. Brush, of Mt. Vernon, West Chester.
3d District, Herman Bendell, of Albany.
4th District, E. Beach, of Gloversville, Fulton Co.
5th District, I. N. Goff, of Cazenovia, Madison Co.
6th District, I. C. Edson, of Windsor, Broom Co.
7th District, Francis M. Hamlin, of Auburn, Cayuga County.
8th District, F. J. Baker, of Lockport, Niagara Co.
From the Society at Large, appointed by the President, W. W. Potter, of Buffalo.

Dr. Milton Josiah Roberts, of New York, read a paper on

ANATOMICAL GEOMETRY AND TOPONYMY: AN INTRODUCTION TO THE SCIENTIFIC STUDY OF DEFORMITIES.

He stated that, next in importance to the notation of physical facts is the determination of their quantitative relationship to other facts—their mensuration. The measurement of anatomical angles was of direct practical importance to every physician and surgeon. For the purpose of accuracy and facility in our description and comparison of the attitude of individuals and the position of component parts, Dr. Roberts defined a number of toponymical terms useful in describing deformities.

For the purpose of studying the normal condition of the human body as to its form and symmetry and the

extent of mobility of its component parts, so as to determine and describe pathological deviations therefrom, a uniform position of the body was suggested. This was, when the individual stood erect, resting equal weight on both feet, with the soft parts over the femoral condyles and malleoli in contact or equidistant from each other, the feet slightly everted, and the head, trunk, and extremities forming practically an unbroken column.

Having pointed out the normal relationships of the planes of the body and limbs, the author declared that it was the business of the scientific physician to endeavor to estimate quantitatively such relationships as soon as they were recognizable. With such information at hand, the amount of pathological deviation therefrom could be determined.

Dr. Roberts suggested the use of the word *diastrophometry*. The angles to be measured in several important examples of pathological deviations of the planes of the body and limbs were then detailed, after which he described three mathematical instruments of his own invention for the measurement of the extent of angular deformities in the human subject.

In conclusion, the speaker declared that, with these three instruments, the orthopædic surgeon would find himself as thoroughly equipped for the accurate measurement of angular deformities of the body as the oculist is, with his ophthalmoscope and trial glasses, for the measurement of errors of refraction.

DR. T. R. POOLEY, of New York, offered some

OBSERVATIONS ON THE USE OF HYDROCHLORATE OF COCAINE.

He said: It is only by an extensive collection of clinical facts that we can reach just conclusions in regard to this drug. This paper embraces my personal views on its use. Of the chemistry, nature, and physiological properties, I shall have little or nothing to say, as they have been sufficiently dwelt upon. Nor do I attempt to give an account of the literature. I make no claim to priority, having used the drug October 17, 1884. I first used a two per cent. solution, procured in New York, but results were not satisfactory. I next used a four per cent. solution of Merck's, which is reliable. I have since used an eight per cent. solution, procured in New York; manufacture unknown.

My remarks will be confined to local anæsthesia in ophthalmic surgery and in affections of the pharynx. My experience is almost entirely limited to instillation in the conjunctival cul-de-sac and injections into the lachrymal sac and duct. I have not injected it into the orbit. There are serious objections to this method.

The use of an eight per cent. solution in the way recommended by Dr. Bradford, of Boston—*i. e.*, using one drop every minute until from three to four drops have been instilled, and performing the operation within from three to six minutes—has been satisfactory, and economizes time. When the lachrymal apparatus was the seat of operation, the solution was injected into the sac. I have used it in a variety of operations on the eye with successful results in the main. In operations on the conjunctiva involving the cutting of this membrane, the anæsthesia is complete. In operations involving subconjunctival connective tissue dissection, the anæsthesia is not complete, but this may be accomplished by instillation of the solution after cutting the conjunctiva in the vicinity of the wound, or by injection beneath the conjunctiva. I am, however, of the opinion that for all practical purposes instillation is sufficient. In operations on the lachrymal apparatus, I have not found instillation sufficient. In such cases it only reaches the puncta lachrymalia. Anæsthesia can only be obtained by injection. Instillation into the nostril enhances the anæsthetic effect. In operations involving the iris, the patients have, as a rule, confessed to pain, although in two instances this was absent. The pain may be removed by the application of a solution to the iris, but on account of protracting the operation, and the exposure of the wound to air and risk to septic infection, I should deem this unadvisable.

My experience with cocaine in cataract extraction has not been large, but sufficient to allow me to speak in the most glowing terms of its value. Among other advantages of cocaine in cataract extraction is one pointed out by Weber, and that is reduction of tension, which prevents the escape of aqueous humor. In the case of children, my preference is, as a rule, for a general anæsthetic. In only one case has any toxic effect been noticed. I have not met with trouble from hemorrhage. An objection which presents itself is the disadvantage which sometimes attends the widely dilated pupil. This can be overcome by the instillation of eserine before the use of cocaine. I have never seen any unfavorable influence on healing. In the therapeutical treatment of affections of the eye the results are not so satisfactory. My experience relates largely to facility of examination of the eye and in the treatment of defective vision. The use of cocaine to facilitate ophthalmoscopic examination has been satisfactory. Although it does not produce as thorough dilatation as atropia, it does not produce the paresis of accommodation with the subsequent annoyance of the patient. I am not particularly acquainted with its use in conjunctival affections before the application of astringents; such use would be difficult and expensive. In cases of corneal injury and ulcers it only produces a temporary alleviation of pain, and I think, owing to the expense, it will rarely be continued throughout the treatment of the disease. The facility with which dilatation of the pupil and alleviation of pain are produced with atropine in conjunction with cocaine, renders this drug of the greatest value in acute iritis. It has occurred to me that it might relieve the pain of acute glioma, although mydriatics are supposed to increase the trouble.

Dr. Moore has suggested its use in some forms of headache, and I have employed it with good results. Also in supraorbital neuralgia, where there was no error of refraction and no muscular weakness. I cannot refrain from referring to two points mentioned by Weber. One is that there is a sensation of coldness. This is real, as shown by the thermometer. The other is that the power of the rectus muscles is augmented some fifteen or twenty degrees.

I think, in conclusion, that, with rare exceptions, general anæsthesia will disappear from ophthalmoscopic surgery; and, secondly, no operation on the eye will be undertaken without the use of cocaine.

DR. KNAPP pointed out one physiological effect of cocaine—that it is a stimulant of the sympathetic ner-

vous system, and it is quite possible that the other effects may be attributed to this action. Its effects are seen principally in three directions, viz., anæsthetic, anodyne, and hæmostatic. There is dilatation of the pupil as well as of the palpebral fissure. The anæsthetic effect is probably due to the paralyzing effect on sensory nerves. It does not affect the motor nerves. It is useful for producing an anæsthetic action on all mucous membranes. Particular reference was made to its use in the tympanic cavity, as constringing the bloodvessels and thus enlarging the cavity. It is also of decided benefit in affections of the nasal cavity As to its action on the eye, he said that a few drops of a four per cent. solution injected behind the globe will produce sufficient anæsthesia to permit removal of the eye without pain, with the exception of that produced by division of the eye muscles. In operations for cataract cocaine has obtained its greatest triumph. In iridectomy there is sometimes no pain. There have been some failures which, however, cannot be attributed to the use of the drug.

Dr. Webster had seen one case of acute glaucoma in which cocaine had been used with the object of relieving pain, but without avail. Iridectomy was subsequently performed, and the case is doing well. In regard to its effects in eyes in which the conjunctiva is much inflamed, the anæsthetic effects are slight, and it takes longer to obtain them. He had done a number of iridectomies with cocaine, but had about made up his mind to abandon its use on account of the danger of wounding the anterior portion of the capsule when the iris is caught with the forceps. The patient feels pain for the first time, and makes a sudden jerk which may prove harmful.

Dr. Sherwell, of Brooklyn, had employed cocaine in the removal of a papilloma of the larynx, but its effect was very unsatisfactory. He had also employed it in painful fissure of the anus, and in the removal of small tumors, but he had never been able to obtain complete anæsthesia.

Dr. F. K. Paddock, delegate from the Massachusetts Medical Society, had used the remedy for the removal of foreign bodies from the eye, and in various affections of this organ, with success. He had also used it to prevent the pain from the application of the cautery to chancres.

Dr. Pooley said that, in regard to enucleation of the eye, he was convinced that the practice of using cocaine would soon be abandoned. There is danger of rapid absorption of the remedy, and the profound impression of a capital operation of this kind without an anæsthetic will not be tolerated by the patient. In regard to the failure reported in the removal of a tumor of the larynx, a prominent laryngologist had told him that cocaine is practically useless in such cases, and interferes with the spasm of the larynx which facilitates the introduction of forceps into the tube.

Dr. S. S. Wallian, of Bloomingdale, presented a paper on

THE PEROXIDE OF HYDROGEN.

After speaking of the chemistry of this substance, he referred to some of its actions. A solution containing twelve or fifteen volumes is sufficiently strong. It is said to have active germicide and antiseptic effects, and to be 40 per cent. stronger than mercuric chloride. It is also a disinfectant of great power, destroying the offensive matter. Only two substances excel it, and these are mercuric biniodide and iodide of silver. It is perfectly harmless and not unpleasant to use. In its application to medicine, its effect is due to the fact that it yields up one volume of oxygen. It will purify the foul air of a room better than anything else, oxygen excepted. When applied to a sloughing ulcer, the pus is destroyed and the sore rendered aseptic. It is of service in mercurial stomatitis and in aphthous ulcers. When applied to a sloughing surface, or a surface containing pus, it sets up an effervescence which continues until the pus is destroyed. On account of this property, it has been used in testing for pus in the urine. Its value is somewhat diminished for this purpose by the fact that in the presence of blood the same effervescence results. It has been used in diphtheria, with asserted good results, in dissolving the membrane and bringing the case to a satisfactory termination.

Dr. Ely, of Rochester, presented a report of a case of

CANCER OF THE LIVER, CHARACTERIZED BY A SERIES OF LOW TEMPERATURES,

occurring in a lady, aged sixty-two, who had an attack of peritonitis in 1882, and afterwards suffered from pains of a vague character, with constipation. There was a family history of cancer, which, in connection with the general signs, led to the suspicion of cancer of the liver, but no physical signs sustaining this opinion were obtained. The general symptoms continued, and the patient died on the three hundred and eighth day of her illness. The autopsy showed that the intestines were united to the bladder and abdominal walls. The substance of the liver showed marked cancerous disease which, however, produced no change in the outline of the organ. The interesting point was the low temperatures which were obtained. In all, 649 thermometric observations were taken. In 460 of these, the temperature was below normal; in 42, it was normal; and in 147, it was above normal. A large number of the temperatures were below 91.5°. The pulse never rose above 94, nor sunk below 55.

It has been generally regarded that a temperature below 91.5° is fatal. In this case, there was no evidence of collapse, and there was no chilling, although the patient felt cold. The reduction of the temperature was frequently associated with the attacks of pain, and the depressing effect of hot weather. This case goes to show that the significance of unusual symptoms is less in their individuality than in their associations, and it would seem to show the necessity of more care in the study of temperature in chronic disease.

In reply to a question, Dr. Ely stated that every ounce of urine passed was measured, and that every particle of food given was weighed. At times there was some albumen in the urine, but there was no reason to suspect renal disease, and at the autopsy none was found. The diet consisted principally of broth, milk, and eggs. The temperatures were taken in the mouth on every occasion. A trained nurse was employed, and the observations were made with a thermometer, bearing the certificate of Harvard Observatory.

Dr. Stoddard had been interested in this study by the results of Dr. Ely's investigations, and he had found

more or less frequent falls of temperature in phthisis and in other chronic conditions. He thought the study of abnormal temperatures was frequently as important as the study of high temperatures in more acute disorders.

DR. T. H. SQUIRE, of Elmira, then described a

CASE OF TUBAL PREGNANCY,

in which rupture occurred while the patient was at stool. A collection of blood in the lower portion of the abdominal cavity soon formed, and was removed with the aspirator. For some time the patient suffered from septic poisoning, and at last an exploratory incision was decided upon. So many adhesions were met with that the operation was abandoned and the wound closed. The patient at first improved after the operation, but finally sank and died nine months after the rupture had taken place. The autopsy revealed the fact that only one inch of the uterine portion of the left Fallopian tube was present; the rest, together with the right, was destroyed, or so diseased as to be scarcely recognizable. Behind the right broad ligament was an abscess containing twelve ounces of pus. As of interest in connection with the preceding paper, the speaker stated that in this case 1200 observations had been made with the thermometer, and in many instances the temperature was subnormal.

DR. L. EMMET HOLT, of New York, then read a paper entitled

DOES QUININE ABORT PNEUMONIA?

After speaking of the growing tendency to deny abortive effects to any remedy in pneumonia, he related cases of intermittent fever in children, in which, from the rapid breathing and the auscultatory signs, he was led to suspect the development of pneumonia; but this was shown not to be the case by the fact that on the following day the child would be running around with scarcely any evidence of pulmonary trouble. In some cases there was dulness on percussion. The breathing was high-pitched and broncho-vesicular in character. These signs were usually found at the apices of the lungs, but in some instances they were confined to the lower lobe. These cases were promptly relieved by anti-malarial treatment. With small doses of quinine they would also improve, and even without any treatment it was doubtful whether they would develop into pneumonia. In the abortive treatment it is considered essential to give large doses of quinine, and early in the attack. In some of these cases the treatment was deferred for one or two days.

As regards diagnosis, the temperature is usually higher in these cases than it is in the first or second days of pneumonia. Another point is the marked want of relation between the rapid breathing and other symptoms and the general expression of the patient. A third point is the presence of splenic enlargement, which usually can be made out without trouble.

DR. A. L. LOOMIS said that every one who has carefully studied the physical signs of pulmonary hyperæmia must be convinced that there are two conditions of hyperæmia differing markedly from each other. First, there is passive hyperæmia; and, secondly, active hyperæmia. The physical signs are markedly different from each other. In passive hyperæmia there is marked change in respiratory murmur, which may lead, especially in children, to the belief that there is partial consolidation of the lung. In active hyperæmia the physical signs will indicate serous effusion into the bronchial tubes. He did not believe that the passive hyperæmia which is the result of malarial infection ever goes on to the production of pneumonia, unless there is something more than the malaria. Such a condition will disappear with the relief of the malarial trouble, and it is probable that the observation of such cases has led to the supposed abortive effect of quinine.

He believed that lobar pneumonia is an infectious disease, and that when it once strikes its blow it will run a certain course which it is impossible to stop. When pneumonia has once shown its presence by a chill, elevation of temperature, and that peculiar change in respiration which assumes a high-pitched, dry character, and is so significant of the development of pneumonia, he believed that it is impossible to abort it. He also believed that it is impossible to have dulness on percussion within twenty-four hours of the beginning of the attack.

There is one more point which seems important, and that is the growing tendency to the belief that the pneumonia of to-day is different from that of ten or fifteen years ago. It seemed to him that the character of all disease had changed within that time. At that time, pneumonia occurring in a healthy individual was not considered of a serious nature.

DR. WALLIAN differed from Dr. Loomis in believing that pneumonia might be produced by malarial poisoning, and he thought that it was possible to have dulness on percussion in less than twenty-four hours after the development, and he cited a case of a man apparently well at five o'clock in the evening, who was seized with a chill at midnight, and by noon of the following day had well-marked dulness over one lobe of the lung.

DR. LOOMIS, in explanation of his statement, said that dulness might supervene in less than twenty-four hours after the chill, but the pneumonia might be in progress before the appearance of the chill. He related a case going to show this in which a patient complaining of not feeling well was tested with the thermometer and found to have a temperature of 101.5°. The temperature was taken every four hours for thirty-six hours. There was not the slightest evidence of pulmonary trouble. There had been no sense of chilliness, but at the end of this time, when the temperature had reached 102.5°, there was a chill followed in a few hours by consolidation.

EVENING SESSION.

At 8 P.M., the Society met for the consideration of the bill for the

ESTABLISHMENT OF A STATE BOARD OF MEDICAL EXAMINERS,

which had been presented by the Committee on Legislation. The bill was taken up by sections. A long debate followed over the question of whether there should be two medical boards or only one, and it was argued that if there was more than one, the standard of examination would vary.

DR. LOOMIS, of New York, and others favored two boards, believing that two are necessary because of the

size of the State, and the number of medical students in it.

An amendment offered by Dr. Roosa, providing for one board of nine members, was adopted by a vote of 60 to 24.

Section 2 was next considered, but after the introduction of several amendments and substitutes, and a great deal of discussion, the whole matter was withdrawn to permit Dr. Jacobi to present a bill which was then before the Assembly.

Dr. Jacobi, in order to bring the matter before the Society, moved the adoption of this bill.

Dr. Vanderpoel then moved that the bill be printed, and made the special order for to-morrow, at three o'clock.

A motion to lay on the table was put, and lost. The motion to postpone was then adopted. Adjourned.

Wednesday, February 4th—Second Day.

Morning Session.

The Society was called to order at 10 A.M.

THE TREASURER'S REPORT

was presented by Dr. Charles H. Porter, and exhibited a balance of $380.

THE COMMITTEE ON THE PRESIDENT'S ADDRESS

presented a report, recommending that a committee of three be appointed on the last day of the session of each year by the President-elect, and it shall be the duty of this committee, with the coöperation of the President, to secure scientific papers, print programmes, and make such arrangements as will best promote the objects of the meeting. And at the next ensuing meeting of the Society this committee is to be appointed the Business Committee.

On motion, it was determined to limit the discussion on the bill to establish a State Board of Medical Examiners to one hour and a half.

Dr. Alfred C. Post, of New York, then read a paper on

SENILE HYPERTROPHY OF THE PROSTATE.

He said that the most important results of hypertrophy are obstruction to the flow of urine and sometimes incontinence. In the early stages of the disease the symptoms are often absent. The first symptom is usually slowness in the passage of urine, and the patient is obliged to rise at night to void his bladder. There is often some sympathetic irritation of the rectum. The neck of the bladder occasionally becomes stretched, and real incontinence follows. This is more rare, however, than constant dribbling. Vesical calculi are frequently the result of hypertrophy, and the symptoms produced by them may be marked. In cases in which the catheter has to be introduced eight or nine inches, and the urine does not flow until the handle is much depressed, there is good reason to suspect hypertrophy. The indications for treatment are, to obviate results of obstruction, improve the constitutional condition, and diminish enlargement of the prostate, or retard its growth. The catheter should be used once or oftener during the day, and the bladder should be washed out. It is of the greatest importance to use a large catheter, even one of 30 mm. if necessary. If stenosis of the orifice or stricture exist, it should be removed. In using the flexible catheter, the distal extremity may be stiffened with advantage by painting with collodion. Complications, as they arise, are to be treated. The application of the actual cautery was recommended in vesical catarrh, and also the injection of from ♏iv to viij of nitric acid in four ounces of water, to prevent the formation of calculi. As regards operative interference in aggravated cases, excision of a portion of the prostate was considered justifiable. In cases in which relief cannot be afforded by the catheter, aspiration, or puncture of the bladder by a trocar through the rectum, may be resorted to.

Dr. T. H. Squire, of Elmira, said that no special skill is requisite to evacuate the bladder in cases of retention from a large prostate, and that but little preparation is required. He suggested the use of a gum catheter of large calibre and of large curve. The soft catheter he considered of great value, and he advised that the aspirator should always be at hand.

Dr. A. Vanderveer, of Albany, thought that the catheter should be used as soon as the symptoms appeared. Rubber catheters are most comfortable for the patient, but silk-web catheters are better for wear. In washing out the bladder, he is in the habit of using the fountain syringe, and he finds the Bethesda water useful in cases of phosphatic deposit. The fluid extract of the stigmata of maize or corn silk, he has also found useful. In cases of enlargement of the middle lobe, resulting in obstruction, the operation advised by Sir Henry Thompson should be practised.

Dr. H. Knapp, of New York, stated that cocaine has been successfully employed in urethral surgery. It reduces congestion, produces anæsthesia, and relieves spasm, thus rendering catheterization easy.

Dr. Lucien Howe, of Buffalo, made a *Demonstration of the Use of the Electric Light in Medical Practice.*

Dr. F. M. Hamlin, of Auburn, then read a paper on

THE OPIUM HABIT,

which contained some startling statistics touching the increase of the habit in this country, as shown by the largely increased consumption of the drug. In 1840, he said, the total quantity of opium consumed in the United States was about 20,000 pounds. In 1880 it had increased to 533,450 pounds. In 1868 it is estimated that there were from 80,000 to 100,000 victims of the opium habit in this country; now they number over 500,000. The growth of the habit has been rapid within the last few years, owing, as he thinks, to the invention of the hypodermic syringe, which has become a favorite method of administering the drug. More females than males are addicted to the use of the drug —the ratio being about three to one—women being subject to a larger number of painful ailments than men. From the time of the publication of De Quincey's *Confessions of an English Opium Eater*, in 1821, until within a few years, physicians have overlooked or ignored the serious consequences of the opium habit, and the people generally have come to look upon it as a comparatively harmless vice. It is now commanding more attention. Dr. Hamlin described the effects, immediate and remote, of the opium habit, speaking, as he said, in some degree, from personal experience, having been induced to enter upon the habit to allay the miseries of sick headache. If opium

be used inordinately during pregnancy it is apt to induce abortion, or if this do not follow, then the child is likely to be defective. He concluded his paper by presenting his method of treatment for the cure of the habit, which he describes as a sudden reduction in the quantity of opium indulged in; not an immediate and total cessation of its use, which would be injurious, but a reduction in quantity covering a week or two weeks, and accompanied with stimulants of a different kind, such as hyoscyamus, belladonna, etc., until a cure is effected.

Under this method of treatment, he thought that every case not connected with a chronic painful affection could be cured. The after-treatment is similar to that pursued in cases of typhoid fever.

Dr. William Hailes, Jr., of Albany, then made some remarks on

THE CULTURE OF BACTERIA,

and exhibited the apparatus used. The tubes shown were similar to those of Koch. His culture-medium consisted of a hundred parts of water to five of gelatine, with two grains of phosphate of sodium. The solution was then clarified with albumen, and filtered.

The matter to be studied is introduced into the culture-medium, the tube sealed, and the subsequent changes studied. Good water does not break down gelatine in less than twelve days; impure water, in three to four days. Demonstration of the technique was made, and the results were shown.

Dr. S. M. Phelps, of Chateaugay, explained a new method of

THE TREATMENT OF HARELIP.

After referring to the defects of other operations, he described and illustrated with diagrams an original method whereby the artistic shape of the lip was secured. This method is applicable to all cases in which at least one-fourth of the lip is preserved.

Afternoon Session.

THE BILL FOR THE ESTABLISHMENT OF A STATE BOARD OF MEDICAL EXAMINERS.

Dr. Jacobi, of New York, said that he had been informed that the Special Committee on Legislation, after a full debate, had agreed upon a report upon the bill to be presented to the Legislature touching a Board of Medical Examiners, and in view of that fact he asked to withdraw the motion made by him yesterday with regard to the representation of medical colleges in the Board.

A resolution from the Committee was reported providing that the draft of the bill reported by the special committee shall be referred to the Standing Committee on Legislation, with the following instructions: That the bill shall be presented to the Legislature after it has been amended so as to provide for one board of medical examiners, to consist of nine members, six of whom are to come from the Medical Society of the State of New York, of which six three shall be selected from those not connected with incorporated medical colleges, and three from those who are members of faculties of incorporated medical colleges; the other three to come from the other two incorporated State medical societies in proportion to their just representation; the board to be appointed by the Regents of the University annually, without disqualification for reappointment; the following subjects to be included in the examination: anatomy, physiology, hygiene, chemistry, pathology, and the practice of medicine, surgery, midwifery, therapeutics; the pay of the examiners to be $800. Section 6 of the Heath bill, relative to anonymous examinations, is adopted; the rest of the bill to be modified to meet the above requirements; the whole to be carefully revised under competent legal advice.

The resolution was unanimously adopted.

Dr. C. H. Porter, of Albany, offered a resolution which was adopted, directing the Committee on Legislation to request the Legislature to enact a law that will enable the State Medical Society to

REGULATE AND CONTROL ITS OWN MEMBERSHIP.

Dr. Wm. F. Mittendorf, of New York, then made some

REMARKS ON THE TREATMENT OF GRANULAR LIDS.

The frequency of this affection, he said, is due to three causes: 1, the insidiousness of the disease; 2, the inefficiency of the remedies employed, and, 3, the indifference of the patients. In examining asylums or public institutions, hundreds of cases are discovered, the existence of which had not been suspected; parents or other relatives of patients, suffering from granular lids, will often not know that they have sore eyes, when, upon eversion of the lids, granulations are discovered that must have existed for months. It is on this account that our present plan of treatment is so slow, the changes of the conjunctiva being such, at the first visit of the patient, that it is often impossible to effect a perfect cure.

The remedies employed for this disease may be divided into two classes—the metallic and the organic. According to their power as germicides, the former ranks as follows: nitrate of silver, mercury, sulphate of copper, sulphate of zinc, acetate of lead, and alum. Of the second class, the principal ones are balsam of copaiba, muriate of hydrastin, tannin, and jequirity.

True granular lids consist in accumulations of lymph cells and granules in the deeper portions of the conjunctiva, and are probably the result of the invasion of a special micrococcus; after the disease has passed through different stages, it results in cicatrization of the conjunctiva. In the first stages, the metallic astringents are indicated; in the later, the organic ones—especially the balsam of copaiba diluted with nine parts of vaseline is here of excellent service. If there is much swelling of the conjunctiva, the hydrochlorate of hydrastin will answer better than anything else, but its application is very painful, and should be preceded by the use of the muriate of cocaine. In fact, all painful applications to the eye should be mitigated by using a little cocaine a few minutes before the astringents are employed. Tannin is of great service in milder cases.

There are two affections that are frequently classed among granular lids; these are the follicular and the chronic blenorrhagic conjunctivitis. The former depends more or less on a scrofulous diathesis, and should be treated by hygienic measures principally; but a two to four grain solution of bichloride of mercury applied once a day to the exposed conjunctiva is of great service. The latter depends more upon peculiar excrescences of

the conjunctival epithelium, and it is principally benefited by the use of a ten grain solution of nitrate of silver, and later by the use of the balsam of copaiba. If all these remedies fail, and if there is pannus, the use of jequirity is indicated. It should never be used by the general practitioner, for unless its action is carefully watched, it may destroy the eye. Its use *should not be for granular lids, but for pannus.* A very convenient way to use it is to have a trituration of jequirity and gum acacia, which will keep for years, and of which as much as the point of a penknife will hold is to be mixed with a teaspoonful of water; after allowing it to stand in a watch-glass for about an hour, it is ready for use, and may be applied to the everted lids by means of a small brush.

The indifference of the patient, and the consequent carelessness in the use of towels and basins that are used by others, are causes of the transmission of the disease to others, and hundreds of inmates of our large public homes may be affected by a new arrival in a very short time.

DR. O. D. POMEROY, of New York, then presented a paper on *Tests for Unilateral Deafness*, which was read by title.

DR. MERCER, of Syracuse, reported

TWO CASES OF LIGATURE OF THE FEMORAL ARTERY.

The first case was that of a man cut with a butcher's knife. He failed to find the bleeding vessel in the wound. An Esmarch's bandage was applied, the femoral artery tied, and a satisfactory recovery ensued.

The second case occurred in a patient who met with a severe fall, a few days subsequent to which he observed a swelling below the knee, accompanied with pulsation, and swelling of the calf supervened. When admitted into the hospital there was pain in the calf, and a thrill was observed over the swelling, and a characteristic bruit was heard. Pressure over the femoral caused these signs to disappear. Traumatic aneurism was diagnosticated, and the femoral artery was tied in Scarpa's triangle. Swelling has decreased since the operation, and the case is still under observation.

DR. POST, of New York, alluded to a case in which hemorrhage occurred on the second day after an operation on the thigh. The femoral was tied. A few days later hemorrhage recurred. The femoral was found to be firmly occluded, and it was decided that the hemorrhage came from the distal extremity of the artery. Pressure and elevation prevented its recurrence.

DR. F. N. OTIS, of New York, exhibited an

APPARATUS FOR THE REMOVAL OF DÉBRIS FROM THE BLADDER

in cases of rapid lithotrity, which was intended to overcome the dangers of clogging and the complication incident to other instruments. A practical point in the use of the instrument is, that if the receiver be filled with glycerine the discoloration of the urine by blood does not interfere with the observation of the falling débris.

DR. OTIS also presented some points in

THE TREATMENT OF URETHRAL STRICTURE BY COMPLETE DIVISION.

Stricture, he considered to be due in all cases to bands of cicatricial tissue. In several thousand cases he had failed to find a calibre of less than thirty-two millimetres. Once in seventy cases, the urethra had a calibre of forty millimetres. It is commonly believed that the orifice is the smallest portion of the urethra. In forty cases out of fifty, the orifice has been of the same calibre as the canal. He had never seen prostatic enlargement in old men in whom the orifice was not contracted. When it was of the same size the glans was atrophied. He had seen many cases, especially in children, of serious reflex disturbances, which were removed by division of a contracted orifice. Contraction of the orifice is often a cause of spasmodic stricture of the membranous urethra simulating true stricture. In 90 per cent. of cases of true stricture, the stricture is in the anterior portion of the urethra. These anterior strictures should be removed before treating the apparent posterior strictures. The results of the cutting operation he considered permanent—if it be done thoroughly. If the larger instrument cannot be inserted, a smaller one should be used to prepare the way. In regard to the relation of the size of the urethra to that of the penis, his previous views have been confirmed by further experience. In a penis of three inches circumference the urethra has a calibre of thirty millimetres; of four inches, of forty millimetres.

DRS. POST and VANDERVEER endorsed the views advanced by Dr. Otis.

DR. J. E. WINTERS then read a paper on

MATERNAL WET-NURSING AND ITS RELATION TO INFANT MORTALITY,

containing numerous statistics, both European and American, showing the great difference in the mortality of children who are nursed by their mothers and those who are hand-fed or wet-nursed. The average mortality among the latter was claimed to be four or five times as great as among the former. He also claimed that many physical and mental ailments were attributable to the latter.

DR. A. N. BELL, of Brooklyn, endorsed the arguments stated, and cited statistics in their corroboration.

DR. ELY, of Rochester, dissented from the views. He recognized the importance of maternal nursing, but he thought he had seen life prolonged and saved in certain cases by substituting wet-nursing. The statements in regard to the moral qualities of hired nurses being imparted to children nursed by them, he thought could not be proven, and that when the nurse was healthy, wet-nursing did not increase the mortality.

DR. TOWNSEND said that he had experimented on the artificial digestion of cow's milk, but that his results were unsatisfactory. In his opinion, the nurse's milk came next to the mother's.

DR. JACOBI said that a human child thrived better on human milk than on any substitute for it. His experience led him to believe that syphilis among wet-nurses is not so common as might be inferred from Dr. Winter's paper.

DR. MITTENDORF said that the facts are against the statements made in the paper. He is connected with several institutions in which the mothers or wet-nurses suckled the infants and the mortality had decreased since this plan was adopted.

DR. WINTERS, in reply, said that he dealt almost exclusively with facts; that he had had a large experience in

children's asylums; and that some of the speakers, in forming their conclusions, had left out of consideration the nurse's child. He still maintained that artificial feeding was better than wet-nursing.

Dr. W. C. Jarvis, of New York, exhibited *A New and Powerful Battery*, which did not need replenishing for many months. The elements are carbon and zinc, but the composition of the fluid is not given.

Dr. I. N. Goff, of Cazenovia, said that there was a cell manufactured in Cazenovia with chloride of sodium and bichloride of mercury in solution, and it never exhausts itself.

Dr. Vanderveer, of Albany, then made some observations on

ABDOMINAL SURGERY

as practised by Mr. Lawson Tait. He described Mr. Tait's method as observed by himself, and cited illustrative cases. He then reported five cases of abdominal section which he had recently performed, four of which were successful.

Dr. Phelps, referring to the fact that Mr. Tait did not use antiseptics, expressed the opinion that their use was very important.

Dr. Post believed that experience was in favor of their use.

Dr. Vanderveer said that he would not think of performing certain operations without using antiseptic precautions.

Evening Session.

Dr. B. F. Sherman delivered *The President's Address* before a large audience in the Assembly Chamber, taking for his subject,

MEDICAL EVIDENCE.

After some general remarks on the subject of medical witnesses, he referred to medical experts. The definition as follows was accepted from Elwell:

"Extra knowledge in questions of science, skill, trade, business, or other matters requiring special knowledge, qualifies the person thus informed to give opinions in courts of justice." The expert comes to the results, constituting his opinion, which is to be received in evidence, from his own private study, observation, and reflection. This kind of evidence is not of the clear and positive nature or of the value of that of facts, for the same guards cannot be thrown about the opinion of experts as are brought to bear upon the jury. This kind of evidence is, however, of great importance, although to be received with caution.

He then gave a résumé of the history of medical evidence. The importance of this subject to questions relating to life, property, and, what are dearer than either, character and reputation, requires that the physician be prepared to fill the position of medical witness with credit to himself, for, while ignorance and deception may triumph in the sick-room, in open court they can find no protection. The duties and responsibilities of medical witnesses were next taken up. While the study of works on medical jurisprudence is important, the physician needs sometimes more to prepare himself for the duty of formulating and giving opinions that may be received as facts by the court and jury.

The following rules have been given by Dr. C. B. Coventry, of Utica, to be followed by the medical witness, for his own protection, and to give force to his testimony:

1. He should listen attentively to the testimony as to all the facts in the case, and avail himself of every authentic means of forming a correct opinion.

2. He should studiously guard against being biassed.

3. The medical witness is not to take into consideration the influence which his testimony may have on the prisoner or the case under consideration.

4. The expert is called to testify as to the bearing of the testimony given, and must receive as true all evidence which is unimpeached.

5. The medical witness should not assume the province of the jury, as, for instance, saying that a particular wound was the cause of death, but only state what would be the ordinary effect of such wound.

6. The medical witness should have his mind fully prepared before taking the stand. He should keep as cool as possible, and avoid the introduction of any expression, or opinion, not immediately connected with the cause before the court.

The witness should avoid being drawn into discussion while upon the stand, and he should fully comprehend the question before answering. In questions to which a categorical answer is demanded, the witness should ask the court for permission to explain before answering.

Before answering hypothetical questions, the witness should weigh every word, and then confine his answer to the supposed case. If the question involve an impossibility, the witness should decline to answer it.

The speaker closed his paper with a few remarks on apparently simple questions sometimes put by counsel in order to embarrass the witness, such as: What is insanity? What is a wound? When is a wound dangerous to life? Answers to such questions should always be guarded.

A vote of thanks was tendered to Dr. Sherman, and the Society then adjourned to the Delavan House, where the *Annual Dinner* was served.

Thursday, February 5th—Third Day.

Morning Session.

MISCELLANEOUS BUSINESS.

A communication on preliminary education from the New Jersey State Medical Society was referred to a special committee.

On motion, it was resolved to publish the transactions and list of members separately. A resolution requesting the County Societies to hold their annual elections in the first three months of the year, was adopted.

The Richmond County Medical Society presented a communication protesting against the too hasty adoption of the new Code by the State Medical Society.

Dr. S. O. Vanderpoel, of New York, then read a paper entitled

DOES QUARANTINE PROTECT?

The probability of the occurrence of cholera renders this question pertinent. The dissemination of the disease is attributed to the Mecca pilgrims. Its natural home is Calcutta. The measures enforced to prevent its spread are inspection during the period of migration, at an island in the Red Sea, and at the seaport of Mecca.

Owing to sanitary inspection during the past eight years the spread of cholera by the Mecca pilgrims has been prevented. The recent epidemic in Egypt was attributed to the fact that Great Britain had evaded the quarantine regulations. If quarantine be effectively carried out, cholera could not occur. But if cholera once acquire a foothold—quarantine is useless. Then local hygienic measures are to be used. Cholera can only come to this country from Europe.

If a thorough medical inspection of individuals and of clothing coming from distant ports, if suspicious cases be isolated and their excretions disinfected, it is almost impossible for the disease to extend to this country.

If a vessel comes to our shores with cholera on board, it should not be allowed to reach the mainland. Passengers should be disembarked and kept under close observation for ten days, and ten days after the last case has appeared, they may be allowed to proceed. There are only five ports in this country at which steerage passengers are landed, viz.: New Orleans, Baltimore, Philadelphia, New York and Boston. A rigid system of inspection should be begun at once, and it will be our own fault if cholera reaches our shores.

DR. H. I. BOWDITCH, of Boston, fully endorsed the views expressed by Dr. Vanderpoel.

The following resolution was then adopted and ordered to be transmitted to the President of the United States:

Resolved, That it is the sense of the New York State Medical Society that the United States Government should, in view of the probable importation of cholera poison during the present year, promptly take steps to enforce proper sanitary measures at foreign ports where the disease exists.

DR. LEWI exhibited an

APPARATUS FOR IRRIGATING THE ABDOMINAL CAVITY

and all deep-seated wounds. The apparatus is on the principle of the fountain syringe, and warm water does the work of sponges.

The President-elect announced the appointment of the following members as

THE COMMITTEE ON PROGRAMME:

Drs. W. W. Potter, Lewis, and Phelps.

On the report of the Nominating Committee, the following

OFFICERS FOR THE ENSUING YEAR

were then elected:

President.—Albert Vanderveer, M.D., of Albany.

Vice-President.—Alfred C. Post, M.D., of New York.

Secretary.—Wm. Manlius Smith, M.D., of Syracuse.

Treasurer.—Charles H. Porter, M.D., of Albany.

Censors. Southern District—Drs. F. A. Castle, G. H. Fox, David Webster, all of New York.

Eastern District—Drs. Lewi, N. L. Snow, of Albany, and Leroy McLean, of Troy.

Middle District—Drs. Alonzo Churchill, of Utica, J. A. Griffin, of Constantia, and Robert Frazier, of Camden.

Western District—Drs. Theodore Dimon, of Auburn, M. S. Kittenger, of Lockport, and —— Little.

For College of Medicine, Syracuse University, I. N. Goff, of Cazenovia.

Committee on Medical Ethics.—Drs. A. Jacobi, of New York, Arthur Mathewson, of Brooklyn, and J. W. Whitbeck, of Rochester.

Honorary Members.—Drs. J. A. Cabell, of University of Virginia, J. T. Whittaker, of Cincinnati, T. G. Wormley, of Philadelphia, and T. S. Clouston, of Edinburgh.

Adjourned.

CORRESPONDENCE.

NEPHRECTOMY AND NEPHROTOMY.

To the Editor of THE MEDICAL NEWS.

SIR: In answer to a request to furnish me with a brief account of his nephrectomies and nephrotomies, Mr. J. Knowsley Thornton has kindly written me the following reply. His success is so remarkable, all of the nephrectomies being by the ventral incision, that I have taken the liberty to send you his letter for publication. It will be observed that the vesical end of the ureter was fixed outside of the abdomen in seven cases. In some recent discussions at the London Medical Societies theoretical objections were urged against this procedure; but its uniform success is a complete vindication of its merits in preventing the access of the septic material contained in the ureter into the deep wound. I am, very truly, yours,

S. W. GROSS.

PHILADELPHIA, January 31, 1885.

22 PORTMAN ST., LONDON, W.,
January 5, 1885.

DEAR DR. GROSS: I have had eleven nephrectomies, all by abdominal section, and all have recovered and are well. In case 2, I had already performed a lumbar nephrotomy, and failed to improve the condition of the patient by drainage. I utilized the opening for drainage after removing the kidney. Case 6 has not derived much benefit, and has, I think, disease of the other kidney and bladder.

NEPHRECTOMIES.

1. Æt. 7. Congenital hydronephrosis. Ureter a fibrous cord. Weight of fluid and kidney about 7 pounds.

2. Æt. 26. Scrofulous kidney, weighing 18½ ounces. Langenbuch's incision. Ureter brought up and pinned outside.

3. Æt. 58. Calculous pyelitis. Sac weighed 5 pounds, and contained 20 pints of pus. Langenbuch's incision, and ureter pinned outside.

4. Æt. 53. Sarcoma of the capsule, weighing 11 pounds. Ureter dropped, and sloughed and came away through drainage opening in 40 days.

5. Æt. 42. Wound of ureter during previous ovariotomy.

6. Æt. 26. Scrofulous pyonephrosis. Langenbuch's incision, and ureter pinned out.

7. Æt. 28. Left kidney removed immediately on finding that I had cut a piece out of the ureter in attempting to remove a retroperitoneal cystic tumor. Langenbuch's incision, and ureter pinned out.

8. Æt. 49. Calculous pyonephrosis. Large uterine fibromyoma removed at the same operation.

9. Æt. 32. Calculous hydronephrosis. Langenbuch's incision, and ureter pinned out.

10. Æt. 48. Scrofulous or tubercular kidney. Langenbuch's incision, and ureter dropped.

11. Æt. 35. Hydronephrosis. Langenbuch's incision, and ureter pinned out.

NEPHROTOMIES.

1. Æt. 23. Pyelitis. Lumbar incision and drainage. Kidney has returned to normal size, and all pain has gone, and patient in perfect health.

2. Tubercular kidney. Lumbar incision. Pain relieved, but fistula never healed. Patient eventually died of suppression of urine, with disease of other kidney.

3. Æt. 25. Scrofulous kidney. Lumbar incision and drainage. Subsequent successful nephrectomy.

4. Æt. 30. Cysts of both kidneys. Lumbar incision and drainage. Recovery.

NEPHROLITHOTOMIES.

1. Æt. 23. Combined abdominal and lumbar incision. Rapid recovery.

2. Æt. 43. Lumbar incision. Slow recovery, but perfect.

3. Æt. 40. Lumbar incision. Slow recovery, but perfect.

With all good wishes for a prosperous and happy New Year.

Very truly yours,

J. KNOWSLEY THORNTON.

DR. S. W. GROSS, Philadelphia.

NEWS ITEMS.

CHICAGO.

(From our Special Correspondent.)

HOME FOR INCURABLES IN CHICAGO.—The will of the late Clarissa C. Peck (widow of Philander Peck), who died Dec. 22, 1884, was admitted to probate on the 7th inst. The Peck estate is a very wealthy one, and Mrs. Peck's share amounts to nearly $1,000,000. The chief bequest of the will is that of clause 34, which provides for a home for incurables in this city. The bequest of all the property of the testatrix, not otherwise bequeathed, is to this noble purpose. The exact amount of the bequest is not definitely known, but i will exceed $600,000. The sum of money, to be expended in the erection of suitable buildings, in furnishing the same, and in fitting up the grounds, is limited to $125,000. The site of the Home will be in the city of Chicago, or township of Hyde Park, Cook County. A corporate organization is directed to be founded under the statutes of the State of Illinois within two years after the death of the testatrix. Among the trustees and corporators of the corporation occurs the name of Charles Gilman Smith, M.D. (University of Pennsylvania, 1851).

The testatrix alludes to the scope of the institution and the functions of the trustees in the following terms: "While I wish said institution to be open to all incurables without distinction up to the limits of its means and capacity, yet I direct that its Board of Trustees shall have full power to exercise their discretion in regard to the admission of patients, and also to the terms and conditions under which patients shall share in the benefits of said institution, and that said Board of Trustees shall have full and unrestricted power and control in all respects, subject only to the limitation that they shall endeavor to carry out the general policy herein indicated, and accomplish the greatest good possible for poor incurables with the means placed at their disposal."

A word in regard to the character of the testatrix. Mrs. Peck was the widow of one of Chicago's oldest and best-known residents. She has always taken the liveliest interest in all charitable and benevolent enterprises. Mission work, however, in particular, occupied her attention. The bulk of the property is in Government bonds and railway securities. A Home for Incurables has been, for a long period of time, one of Chicago's chief necessities in charitable institutions.

MONTREAL.

(From our Special Correspondent.)

A LARGE CALCULUS REMOVED BY LATERAL LITHOTOMY.—DR. KINGSTON, at a recent meeting of the Montreal Medico-Chirurgical Society, exhibited a huge calculus which he had removed by lateral lithotomy from the bladder of a young man, aged 21 years. The stone was composed of uric acid internally and of phosphates externally, and weighed, when removed, 5 ounces, 5 drachms. Its greatest length was $3\frac{1}{8}$ inches. Its greatest breadth, $2\frac{1}{8}$ inches. Its greatest thickness, $1\frac{1}{4}$ inches.

The stone was removed with considerable difficulty after forty minutes' manipulation. Dr. Kingston remarked that Sir Henry Thompson had lately stated that it was impossible to remove a stone weighing more than three ounces by the lateral operation, yet the stone he showed weighed nearly twice three ounces and had been extracted by the lateral method, the patient making a rapid and complete recovery.

THE HALIFAX, N. S., MEDICAL COLLEGE during the past year has lost three of its professors, and at one time it was thought that it would have to relapse again into a preparatory school, owing to the difficulty in finding suitable men to fill the vacant chairs. But by strenuous efforts on the part of the faculty the present difficulties have been tided over. The school is now in a fairly prosperous condition and has a class of forty students.

THE DANGER OF ASIATIC CHOLERA.—The report of the National Board of Health for the year 1884 was transmitted to Congress on February 2. An outline is given of the movements of the several epidemics of Asiatic cholera which occurred in this country in 1832, 1849, 1854, 1866, and 1873, and particular attention is called to the dangers to which the country is exposed by the recent prevalence of the disease in Western Europe. In the absence of specific appropriations, all investigations have been suspended, and an appropriation of $43,000 is asked for. In addition, it is earnestly recommended that an appropriation of $500,000 be made to be expended in aid of State and local boards of health in preventing the introduction and spread of contagious or infectious diseases. Asiatic cholera, the report says, is a disease which is not limited in its ravages by latitude or longitude, and in the event of its appearance in this country, will require the utmost vigilance to prevent its spread.

MEDICAL FEES IN THE ARGENTINE REPUBLIC.—According to a statement published in the *British Medical Journal* (Jan. 10, 1885), a high pecuniary value is placed upon medical opinion in the Argentine Republic:

"The ordinary charge for a consultation at a medical man's house is said to be two dollars (about 8s.); for a visit, four dollars, say 16s.; for attendance at confinement when all goes well, about £20; but when any special care or operation is required, these fees amount up to hundreds of pounds. Accounts for medical attendance are sent in and paid without remark, which would make the hair of a paterfamilias in the 'old country' stand on end. My friend mentions the following fees as having been lately obtained by doctors who, though of good standing, are not looked on as 'stars:' For extraction of ovarian tumor, £1200; amputation of arm, principal, £600; amputation of arm, two assistants, each, £400; delivery with operation, £400; attendance during typhoid fever, £200; visit by a physician for dropsy, £50; consultation fees, £20 and upwards.

"Much depends, of course, on the position of the patient, but there are sufficient wealthy people to make up for any small fees or gratuitous work which may have to be done among the poorer classes.

"The statements given above are confirmed by another correspondent, who states that a friend of his paid £100 for attendance at the confinement of his wife, and adds that the charges by dentists are on a like magnificent scale, as much as £5 or £6 being paid for stopping a tooth. There, however, appears to be one important condition: before a doctor is allowed to practise in the Argentine Republic, he must pass an examination, and be licensed by the Government Medical Board; and before he can do this he must, of course, be master of the Spanish language. The population of the country is so cosmopolitan, that the more modern languages he speaks, the better will be his chances for success."

THE FRENCH SURGICAL CONGRESS was recently organized by a commission, the members of which are Prof. Trélat, President; Profs. Verneuil, Hourteloup, Chauvel, Bouilly, Ch. Monod, and S. Pozzi, Secretary.

The Commission has rearranged the rules which were discussed last session.

The Congress aims to establish relations between native and foreign practitioners interested in the progress of surgery. The sessions will be held at Paris. The questions to be discussed at the next meeting are:

1. Etiology and pathology of surgical infection.
2. The indications furnished by examination of the urine to practical surgery.
3. The best dressing for wounds to be employed in military surgery during a campaign.
4. Care of cold abscess.
5. Indication for operation in deep wounds of the abdomen.

The Commission of Organization requests papers on the following questions:

1. The comparative value of iliac and lumbar anus in cancer of the rectum.
2. Indications for gastrostomy.
3. Origin and nature of coxalgia.
4. Indications for trephining of the skull in traumatic lesions.
5. Treatment of the pedicle in ovariotomy and hysterotomy.
6. On the operation for tumors included in the broad ligament.—*L'Union Médicale*, Dec. 20, 1884.

NOTES AND QUERIES.

THE FORCE OF REPUTATION.

It was a pathogenetic microphyte,
That had wandered away from its *habitat*,
And pondered (like Hamlet) on this and that,
By introspection to gain some light—

It had held its own midst germicides.
Was it doomed to die when its family right,
Was to terrorize nations and shake their might?
It had killed more men than war, besides.

Its strength was great, its size was small,
But the fungus of hay (which it knew quite well)
Had strutted about as an *Anthrax* swell,
And developed a power that surprised them all.

Whilst it turned the question round about,
A young microscopist in search of fame,
Detected its presence and gave it a name,
And settled the question beyond all doubt.

And proud once more was the Schizophyte,
As it startled the world and set it agog;
It made fortune and fame for the young "Pathog."
And killed the patient—*though only by fright.*

OPERATIONS ON THE GALL-BLADDER.

REPORTS of surgical operations upon the gall-bladder or ducts, whether previously published or not, are desired for a contribution to an important work; and all facts connected with them will be thankfully received by Dr. J. M. F. Gaston, Atlanta, Ga.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 27 TO FEBRUARY 2, 1885.

PROMOTIONS.

SOMMERS, JOHN E., *Lieutenant-Colonel and Surgeon.*—To be Surgeon, with rank of Colonel, Jan. 9, 1885.

SMITH, JOSEPH R., *Major and Surgeon.*—To be Surgeon, with rank of Lieutenant Colonel, Jan. 9. 1885.

KOERPER, EGON A., *Captain and Assistant Surgeon.*—To be Surgeon, with rank of Major, Jan. 9, 1885.

APPOINTMENT.

RAYMOND, HENRY J.—To be Assistant Surgeon, with rank of First Lieutenant, Jan. 12, 1885.

WEBSTER, WARREN, *Major and Surgeon.*—Granted leave of absence for one year on surgeon's certificate of disability.—*S. O. 20, A. G. O.*, Jan. 24, 1885.

TAYLOR, B. D., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, to take effect between March 15 and April 1, 1885; permission to leave Department limits.—*S. O. 10, Department of Texas.* Jan. 26, 1885.

KEAN, J. R., *First Lieutenant and Assistant Surgeon.*—Ordered for duty in the Department of the Missouri.—*S. O. 23, A. G. O.*, Jan. 28, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

ORIGINAL LECTURES.

SACCULATED PLEURAL EFFUSION PROBABLY ATTRIBUTABLE TO ACUTE MILIARY TUBERCULOSIS OR SARCOMA.

A Clinical Lecture delivered at the Philadelphia Hospital.

BY EDWARD T. BRUEN, M.D.,

PHYSICIAN TO THE HOSPITAL AND ASSISTANT PROFESSOR OF PHYSICAL DIAGNOSIS IN THE UNIVERSITY OF PENNSYLVANIA.

(Reported by Wm. H. Morrison, M.D.)

GENTLEMEN: This man, forty years of age, was admitted to the hospital about three weeks ago. At that time he was suffering from pleurisy with effusion. There was complete flatness on percussion over the axillary and posterior aspects of the chest, and in these situations there was complete absence of respiratory murmur and of vocal fremitus, while on the opposite side there was exaggerated respiratory murmur. Further examination during the progress of the case led to the belief that the effusion was sacculated. Percussion over the anterior portion of the left chest gave resonance from the clavicle to the base. Although this resonance was not perfect, yet it exhibited a marked contrast to the flatness heard over the lateral portion of the chest. Auscultation over the portion of the chest which gave resonance on percussion, revealed a feeble respiratory murmur and some râles.

Another important physical sign was that the tissues of the intercostal spaces were drawn in with each act of inspiration. This led to the suspicion that adhesions existed between the visceral and costal pleura. The explanation of the mechanism of this sign is as follows: Under normal conditions, when the act of inspiration is performed, the chest distends and the lung expands, applying itself closely to the inner surface of the chest. When a pleural effusion takes place, the chest is placed permanently in the position which it assumes in full inspiration. If, under such circumstances, the pleura covering the lung is attached to the pleura covering the ribs, and inspiration be attempted, the chest wall is carried a little beyond the position of full inspiration, and retraction of the interspaces takes place. This is an important evidence in the diagnosis of sacculated pleural effusion.

There are two other symptoms which were very prominently shown by this patient. One of these is marked shortness of breath. This is more pronounced in this patient than it is in many cases in which the side of the chest is entirely filled. I have shown you such cases on previous occasions, but in those we accounted for the absence of dyspnœa by the fact that the effusion had taken place gradually or had existed for a long time, and the unaffected side of the chest had been able to accommodate itself to the increased amount of work which it was called upon to perform. In this patient, I watched the gradual increase of the effusion, and from the time that it began to form up to the present time the dyspnœa has been very marked.

Having made out the diagnosis so far, the patient was given a mixture containing ten grains of acetate of potassium, five grains of iodide of potassium, and half an ounce of infusion of juniper three times a day. Ten drops of tincture of digitalis were given four times a day to support the heart and to secure the diuretic effect of the digitalis. Blisters were also applied to the back of the chest. I did not give jaborandi or pilocarpine, which I have recommended so highly on previous occasions, because the pulse was always frequent, running about 120 per minute, and was feeble and rather dicrotic, and the patient was generally bathed in sweat. I was not deterred from the use of pilocarpine because the patient was bathed in sweat, for I regarded this as simply a transudation from the skin. Pilocarpine exerts a stimulative action on the skin, causing not only a secretion of watery matter, but also the excretion of solid material. The main reason for avoiding jaborandi or pilocarpine was the evident weakness of the heart, for this remedy exerts a decided depressing influence on the cardiac muscle. Where the action of the heart is already embarrassed, jaborandi may cause an arrest of its movements. I therefore carried out the treatment already mentioned and employed inunctions of oleate of mercury in the axillæ and groins.

Although this plan of treatment was thoroughly carried out, the dyspnœa continued so marked that after two weeks' treatment I considered that further measures were required for the relief of this symptom. I therefore performed paracentesis. As I have told you on other occasions, I should not tap the chest in cases of simple pleural effusion, except in the presence of one of two conditions. These are, such dyspnœa as endangers the safety of the patient and the persistence of effusion without any tendency to absorption of the fluid within a reasonable time, say six or seven weeks. In this case, the dyspnœa was so marked that I performed paracentesis earlier, selecting a point on the left side in the eighth interspace in the anterior axillary line. The needle entered an accumulation of fluid, and two quarts were removed. Moving the needle within the cavity, I felt it impinge on a band of membrane, and thrusting the needle backward, it entered another accumulation of fluid, and a pint of liquid was removed. The diagnosis of sacculated pleural effusion was thus established.

The dyspnœa was relieved to a slight extent by this procedure, but not as much as we had reason to expect, for resonance replaced the flatness on percussion over the axillary region, showing that the lung had expanded. I then searched for an explanation of this unusual state of affairs. The heart was the organ first examined. There was found a slight increase of the area of cardiac dulness. As you know, there are two areas of cardiac dulness; one of absolute dulness, the other of impaired resonance, which extends outside of

the area of absolute dulness, and indicates the portion of heart which is covered with lung tissue. In the present case, this area of impaired dulness merged into the area of positive dulness. Auscultation showed a marked enfeeblement of the heart-sounds, and the first sound especially sounded distant. These signs pointed to the presence of pericarditis. Pericarditis is always a secondary affection, and does not, like simple pleurisy, develop spontaneously. The physical signs taken in connection with the inflammation of the pleura, made me quite positive that there was pericarditis, probably secondary to the pleuritis. I have already stated that the increase in the area of cardiac dulness was not marked, but effusion may be present without any decided extension of the area of dulness, for the tendency of moderate effusions is to occupy the inferior and posterior portions of the sac, pushing the heart upwards and converting the area of impaired resonance into one of dulness on percussion.

Although pericarditis was found, yet this did not account for some of the important symptoms. It did not satisfactorily explain the dyspnœa. It did not account for the bronchitis which was present, and it is not usual to have pleural effusion accompanied with bronchitis. Again, there was a temperature record which, during the past three weeks, has continued between 100° and 102°. It has, therefore, been a very even temperature. A rise of temperature is, of course, expected with the development of pleurisy or pericarditis; but when effusion has taken place, the fever subsides. There was also a rapid pulse, which has always been near or above 120 per minute. Profuse sweating was another marked symptom.

If you have noted the symptoms which have been mentioned, you will find that they are compatible with a disease from which I strongly suspect that this patient is suffering, viz., miliary tuberculosis. This process develops in the lymphatic structures of the lung, and usually is a general process extending throughout the whole lung, affecting the lymph structures around the bronchial tubes, and around the arteries which supply the lung—that is, in the peribronchial sheath. This condition makes the lung more dense, and less capable of performing its function of aerating the blood.

Returning to our patient, let us see what evidence can be adduced in favor of this view. On questioning him closely, we find that the family history is somewhat conflicting. The father and mother are still living, at the age of sixty years. There are two brothers who are perfectly well, but one brother died from pulmonary trouble of some kind at the age of eighteen. We also ascertained that the patient first began to have some trouble with the chest about six weeks before he came to the hospital, that the shortness of breath was a marked feature at that time, and continued to increase until he came under observation. In connection with this, we recall the existence of the bronchitis which was present on admission; for the first time I examined his chest, I heard these fine, moist crackling râles which are still present. These fine, moist râles are very significant. There was also exaggerated respiratory murmur, but no evidences of consolidation. These râles could, therefore, only be due to exudation, the result of inflammation, or of exudation of an œdematous character. If there had been bronchitis, it would doubtless have been improved in the course of three weeks; or if there had been œdema from pressure, some modification in the physical signs would have taken place in the course of three weeks. Effusion, the result of the deposit of miliary tubercles, would, probably, be unaffected by treatment. There is, therefore, strong reason for suspecting that the patient is suffering from the deposit of tubercles in the finer structures of the lung. This theory would explain a number of the symptoms. It would explain the presence of the râles. It would explain the temperature record, for an even temperature is reasonably characteristic of tubercular disease. Occasionally there is high temperature associated with tubercular affections; but this is, as a rule, present only in those cases of miliary tuberculosis associated with some suppurative process in the lungs or pleura. But where miliary tuberculosis develops primarily without the presence of suppurative disease, the temperature, as a rule, is found to be between 100° and 102°.

The dyspnœa would also be explained, for not only is one side of the lung incapacitated by the presence of the pleural effusion, but the other lung is infiltrated with the nodular tubercular matter.

I lay some stress on the pulse in making the diagnosis. In pleurisy, there is usually the ordinary pulse of inflammation, which, while it may be rapid, is not a dicrotic, gaseous, compressible pulse. A gaseous pulse, yielding readily under the finger, is compatible only with some serious blood disease. It is the pulse which is found in fevers. Miliary tuberculosis is really a specific inflammation different from the ordinary simple, frank inflammation which occurs in the pleura or pericardium. I regard the persistent, rapid, gaseous pulse, in connection with the other symptoms, as strongly supporting the theory of tubercular trouble.

Then in regard to the sweating. His head is beaded with sweat at this moment, and his bed is continually soaked. Profuse sweating of this character is not found in frank, simple inflammation of the pleura. This cannot be explained by weakness, for the patient is not particularly debilitated. The temperature has exhibited no malarial characteristics, and the sweating has not occurred in paroxysms. I am confident that constant, profuse sweating is one of the most important symptoms of miliary tuberculosis when taken in connection with the other symptoms. The sero-fibrinous character of the pleurisy, reverses the rule which assigns a fibrino-serous character to pleural inflammation due to tuberculosis; yet this exception is not of cardinal importance.

The patient thinks that he has lost within the last six months at least forty pounds. This is another symptom of importance; because in case the diagnosis of tuberculosis falls, a reserve diagnosis may be substituted of malignant disease of the mediastinum, sarcomatous in character, with secondary simple inflammatory disease of the left pleural sac. Sarcoma occurs in the young and middle-aged. It is frequently attended with pleural effusion, which, although possible as the result of pressure, is at the same time often of inflammatory origin. The later process is developed either by the pressure or by the extension of irritation to the pleural lymphatics from those of the bronchial glands.

The case is a complicated one; and, while I incline to the diagnosis of miliary tuberculosis, I am also decided not to lose sight of my reserve hypothesis.

ORIGINAL ARTICLES.

A CASE OF GUNSHOT WOUND OF THE INTESTINES TREATED SUCCESSFULLY BY LAPAROTOMY, WITH SUTURE OF THE INTESTINES.[1]

By WILLIAM T. BULL, M.D.,
SURGEON TO THE NEW YORK HOSPITAL.

The propriety of exploring the abdomen for gunshot wounds has been amply discussed by many surgeons, both here and abroad. The majority still oppose it, notwithstanding that the very favorable results of abdominal operations for pathological lesions are generally acknowledged. Otis, Sims, Gross, Dugas, McGuire, Kinloch, and Parkes, in this country; Legouest, in France; and Nussbaum, in Germany, have urgently advocated operative interference. But they have been compelled to frame their conclusions from theoretical considerations and statistical data, and have been unable to support their views by the record of a single successful case. In fact, up to the last twelvemonth, I find but two cases recorded in which thorough abdominal exploration was resorted to by laparotomy. Kinloch, in 1882, opened the belly and sutured five pistol-shot wounds in mesentery and intestine. Two other wounds escaped observation. The patient died in thirty hours. And Mr. Lloyd, of the Queen's Hospital, Birmingham, performed abdominal section for suppurative peritonitis three days after a pistol-ball had perforated the small intestine in two places. The intestine was sewed into the abdominal wound and the cavity drained. Death followed in two hours.[2] Last summer, however, Kocher, of Berne, sutured a pistol-shot wound of the anterior wall of the stomach through an incision in the median line, and the patient recovered. The case is briefly reported in the *American Journal of the Medical Sciences*, Oct. 1884:

"A boy, aged 14, was admitted into the hospital half an hour after having received a wound in the region of the stomach from a pistol-shot, aimed at him from a distance of five paces. He was pale, and complained of abdominal pain; the abdomen was swollen and distinctly dull on percussion inferiorly. Pressure on abdomen caused pain. A quarter of an hour later, hiccough, severe epigastric pain, vomiting, pallor, and symptoms of collapse came on. There was tympanitic resonance from the ensiform cartilage to the umbilicus, with complete dulness from the navel downward and in the flanks. The lightest percussion caused severe pain. Three hours after the injury, laparotomy was performed. On opening the abdominal cavity, in the region of the navel, a great quantity of dark blood escaped. The bullet wound was discovered with comparative ease; it was situated on the anterior surface of the stomach toward the greater curvature, in the direction of the fundus. The wound was circular, with sharp edges, and about half an inch in diameter. The bullet could not be found, nor was there any aperture of exit. The edges of the wound were united first with two catgut ligatures, like an ordinary wound, and then a continuous silk suture was applied for the distance of about an inch, so as to invert the serous coat around the wound. Recovery was retarded by an abscess which formed in the track of the sutures in the abdominal wound."

As a further contribution to this subject, I wish to present the following history: and with it I have the pleasure of showing you the patient. It is now three months, lacking a few days, from the time since the operation was performed, and he has quite recovered his usual health.

Case.—Wm. McE., a truck-driver, 22 years of age, was brought to the Chambers Street Hospital at 10 P.M., November 2, 1884, by ambulance from the Police Station of the 10th Precinct. A half hour previously he had been accidentally shot with a pistol of thirty-two calibre, the ball entering the abdominal wall near the navel. On admission he was found to be perfectly conscious, warm, with a pulse at 96, of good volume; temperature 97.8°; respiration 18. He had vomited solid food before admission. He retched frequently, and complained of great pain all over the abdomen, and had tenesmus. The abdomen was tender, but not swollen, nor tympanitic. The wound of entrance was situated one and a half inches below the navel, and one and a half inches to the left of the median line. It was half an inch in diameter, with blackened edges. The bullet could not be detected anywhere beneath the skin. The wound was not probed. A dressing of iodoform gauze and borated cotton was applied after thoroughly washing the skin with a two and a half per cent. solution of carbolic acid. One-sixth of a grain of morphia was given hypodermically.

Twelve hours later (November 3, 10.30 P.M.), when seen by myself, his condition was as follows: pulse 102; respiration 30; temperature 100.2°. Has severe abdominal pain, although he has received twenty-one minims of Magendie's solution (in four injections) since admission. He has slept for about a half hour after each injection. Has vomited a little watery fluid with particles of food. His urine has been drawn and contained no blood. Nothing has been passed per rectum. The abdomen is normal in appearance (save for the wound) and to the touch, but slightly tender all over. Rectum normal. He has received nothing by the mouth but ice, except (by mistake) a cup of milk, which was shortly afterwards thrown up. A cold water coil has been put on the belly, and the dressing made lighter. A probe could not be made to enter the cavity with gentle manipulation.

Seven hours later, seventeen hours after the accident (Nov. 3, 5.30 P.M.), his condition was practically unchanged. He had passed urine voluntarily. The operation was performed with the assistance of Drs. F. W. Murray and C. A. Jersey, and Drs. Mack, Morton, Kirby, and Ten Eyck, of the house staff, Dr. B. Farquhar Curtis, Dr. C. A. Powers, Dr. A. B. Jessup, Jr., and several others, witnessed it. The following antiseptic precautions were observed:

Two large atomizers sprayed the operating-room, for two hours before the operation, with a 5 per cent. solution of carbolic acid. The room itself (which was 25 by 35 or 40) was heated to 80° F., and all the solutions used were warm. For the instruments and hands, 5 per cent. solution of carbolic

[1] Read before the New York Surgical Society, Jan. 27, 1885.
[2] British Med. Journal, March 24, 1883.

acid was employed. The sponges were fresh from carbolic acid, after having been purified with permanganate of potash, and bleached with oxalic acid (Keller's process). The towels, which were not new, were soaked in 5 per cent. solution of carbolic acid for an hour. The catgut was Kocher's; the large silk for the abdominal wound had been boiled in carbolic acid, but the finer (the "No. 1" iron-dyed silk of Snowden), which was used for the wounds of the gut, was not put in carbolic acid till the operation was begun. During the operation, warm water was used for the towels and for washing the sponges, but the final sponging of the cavity was done with 2½ per cent. carbolic acid solution.

A vertical incision two inches long into the bullet wound showed that it was directed in a zig-zag course through the parietes and actually perforated the peritoneum. The usual incision was then made in the middle line from the umbilicus to just above the pubes. On opening the peritoneum, bloody serum without any fecal masses but containing small clots, flowed out freely (at least two pints), floating the coils of intestine into the wound. On the border of the first portion of gut presenting was a slight incised wound of the serous coat only, which was doubtless made by the scissors. It was tied with catgut over an artery clamp. Several coils of intestine, representing three or four feet in length, were then pulled out of the wound and carefully examined. The intestine and mesentery were coated here and there with clots and flakes of fibrin, and these were so adherent that, to dislodge them and see the surface clearly, it was necessary to rub the peritoneum firmly with the sponge two or three times, and this both on its upper and lower surface. The gut was slightly congested and its coils were not adherent. The guts were placed under layers of towels and occasionally drenched with warm water. The first wound, shown diagrammatically in Fig. 1, encountered was about half an inch in diameter, situated midway between the attached and free border of the intestine, and several feet from the cæcum (Fig. 1). The

FIG. 1.

serous coat was clean cut, the mucous membrane lacerated and everted. It bled easily when its edges were separated, but not till then did yellow feces, of the consistency of gruel, escape. (The same was true of all the wounds. The everted mucous membrane acted as a plug.) The abdominal wound was then plugged with large sponges to shut off the cavity, leaving only space enough for the protrusion of a loop of six inches which contained the wound. This was spread out on a towel and emptied of fecal matter through the bullet wound, and held by both hands of an assistant, The mucous membrane was inverted by making traction with two hooks, so as to convert the round hole into a longitudinal slit, parallel with the transverse diameter of the gut. The peritoneal edges were then approximated by five sutures inserted according to Lembert's method. Iodoform was rubbed along the line of suture. (This plan was followed in all the other wounds.) After removing several more loops the cavity of the pelvis was empty and the cæcum, the sigmoid flexure, and rectum and bladder were inspected after sponging out considerable bloody fluid with clots. The bullet was detected at once, lodged in the upper surface of the sigmoid flexure close to its mesenteric border (Fig. 2). It was just beneath the peritoneum, but

FIG. 2.

on removing it the wound was found to enter the lumen of the bowel, which was quite empty. Three sutures closed the wound. The open pelvis was then protected with sponges and more intestine drawn out from under the left edge of the abdominal wound.

FIG. 3.

A third perforation was encountered similar to the first in size, but situated on the upper surface of the gut near its free border, a fourth and fifth close together and separated only by a bridge of the serous

coat, nearly opposite the preceding one, but an inch higher up (Fig. 3), and a sixth one about three inches further on (Fig. 4). These four wounds were all

Fig. 4.

within a length of four inches of the intestine. The two which were so close together had ragged and everted edges, from which the serous coat was stripped off for a distance of one-eighth of an inch. The bowels contained feces and were treated as before described. But the fourth and fifth wounds were converted into one oval slit by trimming off the ragged edges, and twelve sutures were required to close this, while five each were put into the other two wounds. The oval wound made by trimming the two adjacent ones embraced about one-third the calibre of the bowel, and its axis when sewed up was oblique in direction. The others were parallel with the transverse axis.

A few loops of intestine still remained in the cavity. In removing them the seventh perforation was found, several inches beyond the sixth. It was closed with five sutures. The small intestine, except the duodenum, was now all out. A sponge on a holder was passed into the epigastric and both lumbar regions. No blood or foreign matter was detected. The great omentum was not seen.

The pelvis was again sponged out, this time with a 2½ per cent. solution of carbolic acid, the intestines replaced, the lines of suture being inspected as they were encountered. The wound in the middle line was closed with heavy silk sutures, passing through the entire thickness of its walls, and superficial catgut sutures. The incision in the bullet-wound was sewed up in the same way, a drainage-tube being left at its lower end. Iodoform and borated cotton dressing.

The operation lasted two hours. The ether was not well borne. Shortly after commencing, the pulse was 112, the resp. 38; at the end of the first hour, pulse 132, resp. 44; at the end of an hour and a half, pulse 140, resp. 52. At this time the breathing stopped for a moment, and artificial respiration was resorted to, and the legs elevated for the remainder of the operation. At its close, pulse 134, resp. 39. Whiskey ʒj and tr. digitalis were several times injected subcutaneously, and on being placed in bed, a hot-air bath was given and continued two hours. His strength improved rapidly. Six hours later a cold water coil was applied.

Nov. 4.—9 A.M. (fourteen hours after operation), pulse 120; resp. 27; temp. 99½°. He has had cracked ice by mouth, two enemata of Valentine's beef-juice and whiskey, four hypodermic injections of whiskey and digitalis, and seven minims of Magendie's solution in two injections. Has passed three ounces of urine (sp. gr. 1024, acid, no albumen, many hyaline, few granular casts). Complains of slight pain and constant thirst, and has slept little. Has had occasional hiccough, and twice vomited dark green odorless fluid.

9 P.M., pulse 108; resp. 20; temp. 99½°. Has had ice, Vichy water in teaspoonful doses, two nutritive enemata, and fifteen minims of Magendie's solution in three injections. Vomited the same green matter four times, and had pain afterward, but at no other time. Has slept several hours. A few teaspoonfuls of beef peptonoids, ʒss to water ʒj, given by mouth, but discontinued. Pupils normal; tongue moist, but coated; abdomen tender, but not swollen.

5th.—9 A.M., pulse 92; resp. 26; temp. 99½°. Had by mouth Vichy and hot tea with milk, but no sugar (in teaspoonful doses); by rectum two enemata of Valentine's beef-juice and whiskey; hypodermically twelve minims of Magendie's solution. Has slept several hours, and on awaking is bright and cheerful, complaining only occasionally of pain. Urine, thirty ounces. 6 P.M., pulse 92; resp. 20; temp. 101°. Has had two enemata of beef peptonoids and whiskey. All thus far have been retained. Fifteen minims of Magendie's solution in two injections. Vomited twice a brownish fluid. More abdominal pain and slight swelling and tenderness. Wounds normal. Ice-water coil continued. Rectal tube introduced to relieve tympanites. Urine, nineteen ounces.

6th.—9 A.M., pulse 80; resp. 17; temp. 100½°. Has had beef-tea, Vichy, and hot tea by mouth, two enemata, and fifteen minims of Magendie's solution in two injections. Vomited twice, and had desire to evacuate bowels. Still has pain. Abdomen tender, slightly distended. 6 P.M., pulse 84; resp. 18; temp. 101°. Drainage-tube removed.

7th.—9 A.M., pulse 84; resp. 17; temp. 100°. In the last twenty-four hours he has vomited three times a small quantity of brownish fluid. Alimentation as before, with the addition of small dose of dry champagne. Fifteen minims of Magendie's solution. He has slept much, but is restless when awake, and has little pain, but desires to have a passage. Tongue moist. Abdomen less distended. 6 P.M., pulse 87; resp. 17; temp. 102°. Fifteen minims Magendie. Vomited twice; irritable. After an enema of soap and water, a free watery, ill-smelling movement, containing small fecal masses.

8th.—9 A.M., pulse 84; resp. 17; temp. 101½°. 6 P.M., pulse 84; resp. 24; temp. 102°. Thirty minims Magendie. Nourishment as before. But two enemata. There have been three evacuations similar to the first one: fluid, but not watery; fetid, and containing little flakes and masses of fecal matter. Vomited three times. Suppuration about two of the sutures in the abdominal wound.

9th.—9 A.M., pulse 82; resp. 18; temp. 101°. 6 P.M., pulse 76; resp. 18; temp. 101°. One thin movement. Vomited brandy and soda, and also

bismuth and opium powders, but has retained plenty of peptonized milk, champagne, and beef-tea. Less pain. The wound about the sutures is swollen; and on taking out several of them, there is found a collection of pus external to the peritoneum. It communicates with the suppuration about the track of the sutures. The pus was not decomposed. All sutures are taken out but two or three upper ones. Wound stuffed with carbolized compresses. Cold water coil is withdrawn. The bullet wound is likewise split open through a part of its extent.

10th.—9 A.M., pulse 84; resp. 20; temp. 99½°. 6 P.M., pulse 84; resp. 18; temp. 100°. Two dark-colored passages of pasty consistence. Vomited once or twice very small quantities of contents of stomach. Occasional pain. Abdomen not swollen. The wound gapes widely, but is granulating except at one or two points. Urine similar in character to that passed before. It averages forty ounces per day. Tongue natural. Six minims of Magendie in twenty-four hours.

11th.—9 A.M., pulse 82; resp 20; temp. 99°. 6 P.M., pulse 80; resp. 22; temp 101°.

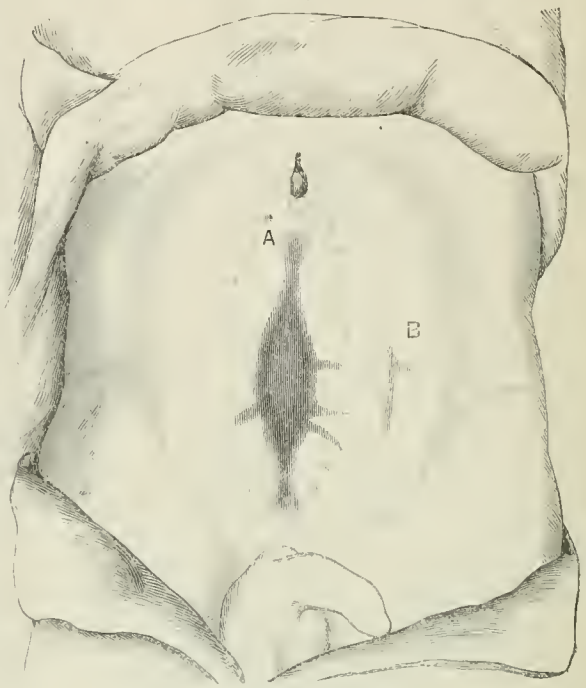
12th.—9 A.M., pulse 80; resp. 24; temp. 98½°. 6 P.M., pulse 86; resp. 20; temp 100°. There have been three movements like the last mentioned in the last forty-eight hours. No vomiting nor decided pain. He complains only of being hungry, and of the discomfort of lying on the back. Abdomen normal but for the wounds, which are granulating.

From this time the patient's convalescence was uninterrupted. The passages became less frequent and more solid; and from the fifteenth day, they were about natural. He vomited on the eleventh, and twice on the twelfth day, but never afterward. His appetite was excellent; and on Thanksgiving day, twenty-four days after the operation, he ate the sumptuous repast provided, including plum-pudding. Several sinuses which formed in the granulating wound required slitting up, and a large number of skin grafts was applied on two occasions.

After the carbolic acid, bals. Peru., and, later, iodoform dressings were employed. At the end of eight weeks, the large wound was cicatrized. He was discharged Dec. 31. The cicatrix was firm, but it is growing softer, and he is wearing a strong abdominal supporter. The functions of the alimentary canal are peformed normally, and he feels—and apparently is—in good health. The urine, however, presents the same morbid products that it did during his treatment.

I am not prepared at the present moment to do more than submit for your consideration the facts contained in this history. To discuss further details, such as the indications for operation, the technique, and the antiseptics and the proper management of all varieties of visceral wounds, would be beyond my present purpose. I hope to have an opportunity for that at a later date, when I shall report a case of wound of the liver, with great hemorrhage, in which the patient died before the operation was completed. But I desire now to call attention to the fact that operative interference for gunshot wounds of the abdomen has been put to a practical test, and that it has been successful. And I hope that other members of this Society may share my conviction, that this plan of active treatment is now justified by this success, and that it should be adopted (within proper limits) to the exclusion of the "let alone" policy.

FIG. 5.



Showing cicatrix of abdominal section (A) and that of the bullet wound (B), three months after operation.

A NOTE ON THE ABSORPTION OF SALICYLIC ACID.

BY N. A. RANDOLPH, M.D.,
AND
SAMUEL G. DIXON,
OF THE UNIVERSITY OF PENNSYLVANIA.

IN view of the fact that the internal administration of salicylic acid and its salts is not infrequently capable of producing or increasing gastric irritability, the advantages of inducing its cutaneous absorption are at once apparent. By the application to the uninjured skin of salicylic acid, rubbed up in a thin paste with olive oil, we have been able to demonstrate the presence of the drug in the urine in each of seven cases in which such application was made. In six of these cases, an existing rheumatic attack was relieved by the application. Of these, in one case only did the application give a negative result.

CASE I.—Man, æt. 30, of rheumatic habit, who had been suffering for three days from rheumatic pains and stiffness in the right thigh. The pain had grown daily worse, until motion of the limb became almost unbearable. He was ordered to remain in bed, and twenty grains of salicylic acid were rubbed into a paste with olive oil, and gently smeared in each axilla. Four hours thereafter, the patient felt some-

what better; and the urine examined at this time showed the presence of the drug upon the application of the ferric chloride test. At noon, on the following day, the patient reported himself as entirely well.

Case II.—Female, æt. 60, suffering from frequently recurrent and severe rheumatic pains in the shoulder. The method of treatment used in the preceding case was here employed, and the patient reported marked relief on the following day, at which time, also, the drug was found in her urine.

Case III.—Female, æt. 28. Rheumatic pains in arm and shoulder. Application as in previous cases. The drug here proved a decided irritant to the very sensitive skin, and was removed in some fifteen hours. Results negative. Urine not examined. Pain and stiffness subsequently disappeared after the exhibition of large doses of sodium salicylate internally.

Case IV.—Male, æt. 25, frequently subject to rheumatism in the left shoulder, and always relieved by the internal use of sodium salicylate; was relieved during a similar attack by the method already described.

Case V.—Male, æt. 34, suffering with severe rheumatic pains in left shoulder.

Thirty grains of salicylic acid were rubbed up in olive oil, gently smeared upon the left side of the abdomen, and covered with rubber cloth. Here, as in the other cases, the urine was tested for the drug in question at the time that the application was made, with negative results. Urine passed in one hour and ten minutes thereafter gave, upon the application of the ferric chloride test, the response characteristic of the presence of salicylic acid; and this reaction was observed in several samples of urine from this patient up to the thirty-sixth hour after the application was made. In twelve hours, the rheumatic symptoms were greatly relieved, and they entirely disappeared within twenty-four hours.

Case VI.[1]—Dr. F., æt. 29. Rheumatic swelling of right knee, the circumference of which was one-third greater than that of its fellow. Patient gave history of previous persistent rheumatic attacks. Salicylic acid and oil (℥ij to f℥j) were spread upon absorbent cotton, and the whole gently wrapped around the knee, which was here too acutely sensitive to permit of any friction. No internal medication was used. In twenty-four hours there was marked reduction both of pain and swelling, and within three days the patient had entirely recovered. During the treatment, swelling commenced in the knee of the opposite side, but disappeared under the same local treatment pursued with the joint first affected. The urine was several times examined during the treatment, and salicylic acid found therein.

This case is of especial interest as indicating that, superadded to the constitutional impress of the drug, there was a specific local effect at the place of its application.

We do not consider that the results of the six experiments here cited would warrant us in an unqualified commendation of this method of exhibiting salicylic acid, but we feel fully justified in suggesting that a fair trial be given it by the medical profession.

Biological Laboratory of the University of Pennsylvania,
February 7, 1885.

[1] We are indebted for the report of this case to the courtesy of Dr. William Gray, who pursued the method indicated at our suggestion.

THE SPINAL ARTHROPATHIES.

A CLINICAL REPORT OF SIX CASES OF CHARCOT'S JOINTS.[1]

By A. SYDNEY ROBERTS, M.D.,

SURGEON TO THE PHILADELPHIA HOSPITAL; INSTRUCTOR IN ORTHOPÆDIC SURGERY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF PENNSYLVANIA.

Case I.—M. K., male, æt. 41, referred to the New York Orthopædic Dispensary from St. Luke's Hospital on May 5, 1879. Hereditary history unusually good. He is a moderate drinker. Health excellent until manifestation of present joint trouble. Married, and the father of five healthy children.

Condition on date of entry: A large nodular tumor was found over the left hip-joint, oval in

Fig. 1.

shape, the long axis of which corresponds with line of Poupart's ligament (Fig. 1). Transverse diameter of normal limb over hip-joint, 22 inches; of affected limb at same point, 30¼ inches. No muscular atrophy detected by measurements of circumference. Left limb 1⅜ inches shorter than its fellow; meas-

[1] Read, by invitation, at a meeting of the Neurological Society of Philadelphia, January 26, 1885.

urements made from the umbilicus. External iliac fossa of left side filled with osteophytes, which add to bulk of tumor. The ligamentous structures about the joint seem entirely destroyed; motion of limb abnormally free in all directions. Head of femur probably absorbed or greatly atrophied. Limb abducted and rotated outward. What appears as the head of the femur is anterior to its normal position, lying under a "shed" of bone, built out from the pelvis, which covers its atrophied extremity like an umbrella. When the patient flexes the limb, the upper extremity of the femur glides forward until it catches under this shed of provisional bone, which, acting as a fulcrum, allows the patient to flex and rotate the limb with ease.

A thorough examination of the patient for evidence of a central lesion, revealed the absence of numbness of limbs, of pain, or of constricting bands; sensation slightly impaired on left side. On right side, reflex action increased on titillation of soles; none on left. No tendon reflex in either limb. Sways with "closed eyes test."

Condition eighteen months later: The patient presented all the marked symptoms of locomotor ataxia. Two years from date, upon which the above notes were recorded (May 5, 1879), he is confined to bed, with complete loss of muscular coördination.

Remarks.—The case exhibits an arthropathy existing four and a half years prior to the development of active tabetic symptoms, and shows a tendency, from early stages, to the formation of osteophytes about the joint, with early atrophy of the upper epiphysis of the femur.

At no time during the progress of the lesion were there developed reflex neural symptoms that would point to joint inflammation.

The joint lesion (swelling and tumefaction) diminished as the active symptoms of ataxia advanced. Provisional callus was thrown out about the atrophied extremity of the femur as a substitute for the destroyed acetabulum.

Case II.—O. P., male, æt. 44. Registered as an out-patient in the New York Orthopædic Dispensary on January 29, 1879. The following notes were recorded.

Hereditary History.—Parents living and healthy; one brother died of phthisis. Patient is married; has three children, two in excellent health; the third has an intrapelvic abscess. (Subsequently died of amyloid degeneration of the kidneys. Patient has had to work very hard, with considerable mental anxiety; no other known cause for present disease.

The left knee and ankle (Fig. 2) are enlarged, the latter more so relatively than the knee. The patient states that seven years ago, while working, a heavy box fell upon him, injuring the ankle. The joint became swollen, and he was "laid up for two months." He recovered, and suffered no inconvenience for one year; the swelling again returned in the same ankle and involved the entire leg. At this time he was incapacitated from work for three months; he recovered, and has had no active joint symptoms since. Has never had an abscess about the joint.

The urgent symptoms at present examination are ose of locomotor ataxia. He cannot walk without staggering, and when attempting to do so in the dark, or with closed eyes, falls. Suffers from ataxic pains in the right leg and arm. Is uncertain in guiding his finger to the tip of his nose, with eyes closed, or in

Fig. 2.

putting his heel on a designated spot. Sensation impaired in right hand and arm: has difficulty in buttoning his coat with that hand. When standing, or walking in his bare feet, he feels as though he were on cushions; vision unimpaired (eye-ground not examined).

On February 4, 1879, Dr. Cloves Adams saw the patient in consultation, and thought him to be suffering from locomotor ataxia in the third stage, with osseous changes in left ankle and synovitis of both knees.

The patient returned to the Dispensary in September of the same year, with a marked elastic swelling of the right elbow-joint (Fig. 3).

A year later (November, 1880) he was referred to the clinic of Dr. E. C. Seguin. He again applied to the Orthopædic Dispensary on February 14, 1881. The ataxic symptoms had advanced; he walked with extreme difficulty. The condition of the joints remained about the same as when last examined, now four months ago.

During November (1881) the patient was critically examined by Dr. S. Weir Mitchell, and pronounced to be in the third stage of locomotor ataxia, with spinal arthropathies of the right elbow and left ankle-joints. It was noted that the circumference of the elbow tumor had materially diminished since the last measurements were recorded (decrease of two and a half inches).

Remarks.—The joint enlargements in this patient presented three characteristic peripheral ataxic conditions:

1st. At the knee-joint synovial irritation, indicated by the physical signs of a chronic synovitis although

at no time during its course was there evidence of inflammation.

2d. A characteristic doughy, nodular ataxic joint tumor of the elbow, largely composed of osteophytes and excessive synovial secretion.

Fig. 3.

3d. Hypertrophy of the lower epiphyses of the tibia and fibula, with but slight synovial irritation.

The peripheral manifestations at the knee and ankle accompanied the earlier symptoms of ataxia; the elbow tumor entered abruptly upon the second stage of the sclerosis. I am indebted to my friend Dr. Newton M. Shaffer, of New York, for the privilege of reporting the above notes.

Case III.—J. H., male, æt. 45; was admitted to my wards in the Philadelphia Hospital on April 3, 1883. The following notes were recorded: A vigorous, well-nourished man, with little personal knowledge of his family or their history. Knew his parents lived to advanced age, but thought both of his brothers had died, and likewise two sisters. Acknowledged to being strongly addicted to the use of alcohol. He thought his present trouble arose from a "dissipated life and constitutional syphilis."

Two years ago, after a debauch, his attention was directed to painful swelling of his right great toe. This lasted a few days, and as the pain and swelling of the toe subsided, the right ankle-joint enlarged. This swelling slowly and painlessly increased, and three months from its onset, the same condition appeared in the left ankle-joint. Without especial discomfort to the patient, this joint enlarged. He continued drinking to excess, and was admitted to the hospital in a state of chronic alcoholism.

An examination two weeks after admission, when all traces of alcoholism had subsided, gave evidence by the following facts of a central lesion: He had suffered from constricting pains about the abdomen, and occasional darting pain in the region of the hips and thighs for the past year. He also experiences considerable difficulty in walking, especially at night. At present, he has a staggering gait. Absence of patellar reflex in both limbs: sways and falls with "closed eyes test," and has difficulty in finding tip of nose with forefinger when eyes are closed.

The metatarso-phalangeal articulation of the right great toe is ankylosed. Both ankle-joints are enlarged apparently by a diffuse hypertrophy of the epiphyses of tibia and fibula. This increase has almost doubled their normal circumference. The subcutaneous tissues are slightly œdematous. The capsules of ankle-joints are distended and elastic.

When first admitted, the tissues about the ankles and legs were swollen, presenting the appearance of diffuse cellulitis. This subsided in a few days from rest and local treatment.

My colleague, Dr. C. K. Mills, saw the patient with me in consultation, and confirmed the diagnosis I had made—of posterior spinal sclerosis, with accompanying arthropathies at ankle-joints.

Remarks.—The joint hypertrophy had preceded any active symptoms of ataxia. The character of the joint enlargement was that of bony hypertrophy, without a tendency to the formation of osteophytes or to nodular irregularity of contour. The possibility of rheumatism or malignant disease was considered and dismissed. A thorough physical examination failed to detect any of the characteristic reflex neural symptoms of an epiphyseal ostetitis.

The history of the progress and course of the ankle-joint hypertrophy, together with the evidence of a central lesion and the negative physical signs of local joint inflammation, all confirmed the diagnosis of an arthropathy of spinal origin.

Case IV.—Dr. A. A. Y., male, æt. 65, resident of Hammonton, N. J. Examined the patient with Dr. S. Weir Mitchell on January 16, 1885. For the substance of the following notes I am indebted to Dr. Woodnutt.

History of patient: Family history excellent. He had always been strong and healthy during youth and up to 1865, though a hard-working farmer. An army life, and three years of extreme exposure prior to the close of the war, found him suffering in 1865 from sharp, wandering pains in the upper and lower extremities; never noticed, however, in the articulations. Loss of power followed in the right leg. Three years later suppurative arthritis attacked the metatarso-phalangeal articulation of the right great toe, and last phalanx of left ring finger, sequestra coming away in each instance.

During 1870 the patient first noticed an œdematous swelling of the right elbow; following shortly upon this, the wrist-joint of the same arm gradually and painlessly enlarged. Then a distention of the capsule of the right knee-joint succeeded. The enlargement of the latter articulation was more rapid than either the wrist or elbow. Rheumatic pains in the joints accompanied the swelling and deformity.

The left limb has been comparatively exempt from pain. Recently, however, the capsule of the knee-joint has become distended and elastic. The elbow tumor has diminished somewhat in circumference during the past four years.

During the past year the distal phalanx of the right index finger has gradually atrophied, without inflammation, and is entirely wanting. The nail and finger end are normal, though somewhat shortened. Pain at present is chiefly in both feet, paroxysmal and erratic, often attacking corresponding points on the legs.

The present appearance of the right elbow and left knee-joint (Fig. 4) enlargements exhibit an irregular

Fig. 4.

nodulated hypertrophy, bearing no resemblance to normal joint outline, and consisting chiefly of osteophytes and abnormal increase of synovial fluid. Motion preternaturally free in all directions; structure of joints apparently entirely destroyed.

Remarks.—The joint lesions first appeared in this patient after ataxia had become established. The appearance of the affected elbow and knee is that of an enormous nodular hypertrophied mass of bone, doubling their normal circumference, associated with synovial distention of the capsule. Osteophytes readily movable within the capsule, and varying in size from a pigeon's egg to that of a turkey.

The atrophy of the distal phalanx of the right index finger is especially to be noted, it being the first instance of complete absorption of the diaphysis of bone that I have had an opportunity of observing.

Case V.—W. H. McC., male, æt. 38, married. Admitted to the Orthopædic Dispensary of the University Hospital in July, 1883.

Hereditary history excellent; no evidence could be obtained of articular disease, rheumatism, or phthisis in any member of his family. He presented at date of examination the appearance of a healthy well-nourished man. Has always worked industriously at his trade of plumber. A moderate drinker. He had constitutional evidence of syphilis, following a chancre contracted in 1863.

The patient attributes the present enlargement of the right ankle-joint to an injury received while working in a cramped position. Following this strain, the ankle became suddenly discolored and swollen, bursting the buttons from his shoes. He was incapacitated for work during the succeeding four days; at the end of a week the discoloration and swelling had about disappeared. His attention was then first directed to a bony enlargement of the right ankle-joint. This slowly and painlessly increased in size without any appreciable interference in locomotion. At present examination the enlargement resembles a simple hypertrophy of the lower epiphyses of the tibia and fibula. The outline of the joint is globular, with slight elasticity of capsule. No pain or reflex muscular spasm.

Record of Spinal Symptoms.—Complains of darting pains about hips. Has difficulty in walking at night. Sways with closed eyes. Complete absence of patellar reflex on both sides. Dr. Horatio C. Wood saw him with me in October of 1883, and pronounced him ataxic.

Remarks.—This case presents an arthropathy that apparently followed a direct traumatism to the affected limb. From careful interrogation, I determined that the acute swelling, and ecchymosis resulted from rupture of a varicose vein, inasmuch as these were numerous, and greatly engorged about the affected ankle. This first attracted his attention to the ankle, the deeper bony growth being detected when the active symptoms of subcutaneous swelling had subsided.

The hypertrophy of the joint has increased the circumference four and a half inches over its fellow.

Case VI.—A specimen of shoulder-joint arthropathy, lately removed at an autopsy held upon the body of a well-marked ataxic, has been referred to me by Dr. S. Weir Mitchell, to embody in this report. The joint had become suddenly and painlessly enlarged in the later stages of the central lesion. It presented ante-mortem all the characteristic symptoms of a tabetic arthropathy: distention of the capsule, abnormal mobility, and the presence of osteophytes. The joint, upon examination, presented the following:

1st. Cartilage covering head of humerus eroded; that upon glenoid cavity irregularly thickened.

2d. Anterior margin of glenoid cavity worn away, allowing the head of bone to rest in position of forward dislocation.

3d. Osteophytes abundant about junction of capsule with anatomical neck. Marked relaxation of ligamentous structures, and distention of capsule.

4th. General hypertrophy of epiphysis, somewhat nodular at margins. Evidences of hydrarthrosis.

The practical deductions to be drawn from a clinical study of the above somewhat anomalous cases, may be briefly summarized as follows:

Period of Development.—1st. The tabetic arthropathies may occur independently, or precede the active symptoms of locomotor ataxia.

2d. They occasionally develop suddenly, late in the course of a posterior spinal sclerosis.

Nature of Lesions.—The peripheral expression of central nerve irritation is characterized by the following changes found in the structure of the various articulations.

1st. A chronic asthenic hyperæmia of the synovial membranes; a hydrarthrosis.

2d. An interstitial atrophy of the epiphyses.

3d. A fungous or rarefying epiphyseal hypertrophy.

4th. The formation of osteophytes and bony stalactites.

These various joint expressions characteristic of the spinal arthropathies may exist separately; but are usually combined in the same subject.

Differential Diagnosis.—They may be readily distinguished from the common inflammatory lesions of the epiphyses by the total absence of the reflex neural phenomena—*i.e.*, of pain, both reflex and local, the apprehensive state regarding joint movements, and the reflex or tetanic spasm of the muscles, always associated with joint arthritis. Abscess is never directly associated with the arthropathies, unless incident upon direct traumatism.

They are more difficult to differentiate from malignant disease of the articulations; but a careful inquiry into the history and course of the lesion, and the presence or absence of central disturbance, are our most reliable guides.

Course.—The progress of the arthropathies is essentially chronic. Occurring, not infrequently, early in the history of the tabetic lesion, they slowly increase, with occasional exacerbations, and years elapse before fully matured. A rapidly developing arthropathy may be associated with the later stages of an ataxia. Their course is self-limiting, though never reparative.

MEDICAL PROGRESS.

Lacunar Caries of the Handle of the Malleus.—Dr. S. Moos, in the *Zeitschr. für Ohrenheilkunde*, Bd. xiv., describes caries of the tympanic bones as a condition frequently existing in suppurative inflammation of the middle ear. The malleus is the bone most frequently attacked, next in order the incus, and least frequently the stapes. The cause of the most frequent implication of the malleus is connected, according to the investigations of Dr. Moos, with the action of the tympanic bloodvessels and their relation to the handle of the malleus. The latter is chiefly nourished by the mucous membrane of the tympanic cavity, which covers also the inner surface of the tympanic membrane, while the outer cuticular layer receives but a small supply of blood. The inner surface of the tympanic membrane, the mucous membrane layer, must therefore be attacked first of all, if caries originate in the malleus. If now, in consequence of a widespread inflammation of the tympanic cavity, the mucous membrane covering the malleus be destroyed, then the vessels of the membrana propria, and finally the periosteum itself, will be undermined and detached. After the loss of these tissues, a granulation rich in vessels spreads in all directions, and finally there remains in the centre of the handle the only remnant of osseous tissue. The caries may still further extend, and at last the head of the malleus may alone remain, held by the ligaments in the upper part of the tympanic cavity. In the occurrence of caries of the handle of the malleus, the destruction of the osseous tissue is principally caused by the production of granulation tissue, and only in the smallest degree by giant cells, by which lacunar cavities are formed at the boundary of the healthy and diseased bone. Moos refers to Pommer's researches, and concludes on the basis of his investigation that granulation tissue plays as great and usually a greater part in the formation of resorption lacunæ than the giant cells, which, according to Pommer, are to be considered the only resorptive organs of the osseous tissue.—*Deutsche med. Wochenschr.*, Jan. 1, 1885.

Incompatibility of Sulphate of Quinine and Potassium Iodide.—Rabuteau, in the *Union Pharm.*, 1884, shows that the sulphate of quinine administered with the iodide of potassium causes anorexia, nervousness, and general malaise. These effects are analogous to those occurring if an iodide containing iodate of potassium is taken, the acid of the gastric juice in this case liberating free iodine. According to Rabuteau, the same result obtains from a mixture of iodide of potassium and sulphate of quinine, and the liberated iodine is the cause of the observed disturbances. He further observes that very serious or even fatal results may occur from their use during menstruation.—*Gazetta degli Ospitali*, Jan. 4, 1885.

Suprapubic Cystotomy.—D. Rohmer, in the *Annales des Organes Génito-urinaries* for Jan. 1, 1885, after a lengthy discussion upon suprapubic cystotomy in hypertrophy of the prostate, concludes as follows:

1. Suprapubic cystotomy is an operation of great importance in patients with prostatic disease, not only in cases of emergency, but also as a curative procedure in case of absolute retention of urine, incurable by other means.

2. To be efficacious in such cases, the operation should be practised seasonably—*i. e.*, before serious lesions of the urinary organs have been established or become incurable.

The Surgery of Scrofulous Glands.—Mr. T. Pridgin Teale, in a recent lecture on the surgery of scrofulous glands, summarizes his treatment as follows:

1. That our guiding principle should be, in the words of Dr. Allbutt, that, "whenever septic material is contained in the system, we rest not till it be expelled, and its burrows laid open and disinfected."

2. That in a very large number, in a majority, of these instances of scrofulous neck which have come under my care, there was no evidence of any constitutional taint or weakness. The origin of the ailment was clear and defined, bad drains in many instances, scarlet fever,

mumps, etc. The cases were often isolated instances in families free from any tendency to constitutional disease. Health was restored to perfect vigor after the destruction of all degenerate or septic material. The removal of the condemned glands was *very rarely* followed by any further enlargement of glands, or by the need of any repetition of operation.

3. That surgical interference is not only justifiable, but demanded, in the following conditions:

(*a*) Whenever a sinus resulting from a degenerating ymphatic gland exists.

(*b*) Whenever fluid—*i. e.*, pus—can be detected in connection with an enlarged lymphatic gland.

(*c*) Whenever there are enlarged glands accessible to surgery in a patient in whom a caseous or a suppurating gland has been already discovered.

4. As to glands which, not having suppurated, nor having been proved to be caseous in any one instance, are an eyesore, or are accompanied by lowered health, the question of removal may be considered an open one. Probably in some instances the best method of treatment will be by "cautery-puncture."

Of this method Mr. Teale has had no experience, but it is spoken of most favorably by Mr. Treves in his work on *Scrofula and its Gland Diseases*, page 193, and he has employed it extensively.

As to the surgical treatment of these cases, the following are Mr. Teale's conclusions:

1. That surgery can secure the healing in a very few weeks of gland cavities and sinuses, even though they have existed for years, and of wounds resulting from the removal of caseous and suppurating glands.

2. That in dealing with sinuses, gland abscesses, and decayed or semi-decayed lymphatic glands, the action of the surgeon must be vigorous and thorough.

3. That the visible abscess, which would often be called a struuous suppurating gland, is, as a rule, merely a subcutaneous reservoir of pus, its source a degenerate gland being, *not subcutaneous*, but *subfacial*—*i. e.*, under the deep cervical fascia, and sometimes even submuscular, the communication between the two being a small opening just large enough to admit a probe or director.

4. That it is utterly futile to incise or puncture such a subcutaneous abscess dependent upon a degenerate gland which lies beneath the deep fascia.

5. That when a damaged or suppurating gland has been got rid of before the overlying skin is thinned by advancing suppuration, the resulting scar is insignificant, and not an eyesore.

6. That in almost every instance in which the cure of the disease by operation was followed by a depressed cicatrix, there had been previously a sinus discharging for months, or even for years.

7. That in dealing with a sinus the channel should be enlarged by the knife or by "Bigelow's dilator" and the whole of its granulating surface should be scraped off. Where a sinus is shallow and covered by thin blue skin, this imperfect covering should be rasped away by the scraper, and any cutaneous overhanging edges should be trimmed off by scissors.

8. That in dealing with a sinus or an abscess the surgeon should not rest content until he has discovered and eradicated the gland, always remembering that if it be not obvious, there is sure to be a small track leading through the deep fascia to the missing gland. This opening should be enlarged so as to admit the spoon of Lister's scraper.

9. That when a gland has not suppurated, and is movable, it can be removed by very little dissection, almost by enucleation, and that, as the healing takes place rapidly, the resulting scar is very faint and insignificant.

10. That when a gland has suppurated, and generally when it has become caseous, the capsule should be freely opened, and the contents should be eviscerated by Lister's scraper. This is sometimes easy, the evisceration leaving the stiff capsular case virtually cleaned out. Sometimes it is very difficult to get rid, even by most vigorous use of the scraper, of the tough living stump of gland toughly adherent to the capsule. At times it is well to dissect this remnant away by the scalpel, if the risk of injuring important structures be not too great.

11. That sometimes, after such an evisceration leaving an empty capsular cavity, the finger detects in this wall a bulging of a contiguous gland. This should be pricked through the wall of the cavity, and so reached and eviscerated. In this way in more than one instance I have emptied from one external opening a group of three or four glands massed together, in close contact, and suppurating or otherwise broken down.

12. That the following is a good plan of after-treatment. The cavity having been well cleansed by carbolic acid solution 1 in 40, or by carbolized glycerine 1 in 10, is charged with iodoform. An India-rubber drainage-tube, reaching to the farthest recess, is fixed to one extremity of the wound, the edges of which are carefully and accurately brought together by fine catgut suture. The wound may then be covered by a pad of salicylic silk, or some other absorbent antiseptic substance. At the end of a week the India-rubber drainage-tube should be removed. Where a gland and its capsule have been completely enucleated or dissected out, it is not necessary to renew the drainage-tube. In all other conditions the India-rubber tube should be replaced by one of gilt wire, which should remain until there is reason to suppose that all is healed except the track of the tube. This period will vary from three to eight or ten weeks.—*Med. Times and Gaz.*, Jan. 10, 1885.

THE USE OF THE SHARP-EDGED SPOON IN PUERPERAL ENDOMETRITIS.—DR. PLONIES, in the *Centralb. für Gynäkologie*, after citing several cases of puerperal endometritis in which the cutting spoon was used, says: The list of the preceding cases is not sufficiently extensive to enable a decisive verdict to be given concerning the application of the sharp-edged spoon in puerperal and septic endometritis. It seems to be indicated in every case in which high fever depends upon the retention of putrid membranes. The results will naturally be the safer and speedier the earlier the opportunity is taken for operative procedure; and if trial is made of the means proposed, most probably there will result further progress in the future, in the treatment of this so frequently dangerous disease. However, if the cutting spoon is found to be a prophylactic measure against the complication of puerperal endometritis and sepsis of the generative organs, it, nevertheless, will be subordinate to careful antiseptic procedures otherwise carried out.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,

PHILADELPHIA.

SATURDAY, FEBRUARY 14, 1885.

THE ANTISEPTIC TREATMENT OF TYPHOID FEVER.

WE presume no one will deny that the therapeutics of typhoid fever as practised to-day is far from satisfactory. This being the case, no treatment which promises more favorable results than have been obtained in the past, should go without a thorough examination of its claims before it is rejected. While the antiseptic treatment of this disease has not been received with much favor in this country, it must also be admitted that the actual trials made with it have been too few to justify any conclusions. We believe, therefore, that our readers will be interested in some further exposition of this treatment than has recently appeared in our columns, especially if it reflect the views entertained by such an authority as M. CH. BOUCHARD, whose paper, read before the International Medical Congress at Copenhagen, is published at length in the *Revue de Médecine*, of Nov. 10, 1884.

M. Bouchard characterizes the two forms of treatment—the antipyretic and the antiseptic—in the following language: The antipyretic method attacks a symptom—the high temperature; it is palliative, not curative, and it permits the disease to culminate and recede spontaneously. But the antiseptic treatment strikes at the cause, and its objects are truly curative. Further, Bouchard does not propose to substitute the antiseptic for the antipyretic treatment, but to associate the two.

In the first place, the extraordinary success of the antiseptic method in surgery makes it not unreasonable to expect similar effects upon internal maladies, although the much greater difficulty in securing the action of the antiseptic upon the agent of the disease is admitted, since in the latter case it would appear that the economy must be impregnated before an effect can be secured, while in the former the application is direct. Such impregnation, it is alleged, may destroy the patient before it will destroy the microbe of disease. But such reasoning is fallacious, because it is well known that certain substances, harmless to man, are destructive to microbes; certain microbes flourish in solutions of quinine, arsenic, and antimony, and others perish in the same solutions; finally, the infectious agents of certain infectious diseases, such as dysentery, cholera, and diphtheria, are really limited to the surface of organs, and impregnation of the economy is not essential in order to reach them. Further, medical antisepsis does not propose to kill the microbe, but rather to prevent its proliferation. It is not the ferment, but its incessant renewal, which constitutes the disease. A simple change of soil and of climate is sufficient to influence the fecundity of the higher animals and vegetables. The infected organism is a soil for the microbe, and is it not reasonable to suppose that a change of this will affect its indefinite increase? But these speculations have actual support in facts. Sheep, which are very subject to anthrax in the province of Beauce, are rendered unsusceptible to its inoculation when transported to Algeria.

To many, M. Bouchard will appear to be begging the question, when he declares that mercury in syphilis, quinine in intermittent fever, and salicylic acid in rheumatism, the cold bath—indeed, all antithermic remedies—act as antiseptics. In like manner, he considers that quinine reduces the temperature in typhoid fever by its noxious influence upon the vegetable organisms upon which the disease depends. It is, however, necessary to continue the quinine to maintain the antipyretic effect, and the moment the drug is eliminated, the temperature rises, while quinine does not reduce the temperature in the well man. On the other hand, carbolic acid is a true antithermic. It reduces the temperature of the healthy man as well as that of one who is ill with fever. Its antipyretic influence seems to depend upon a physiological action on the organism of the patient rather than on the agent of infection.

M. Bouchard is satisfied from personal experience that carbolic acid will abort typhoid fever, although this action is not without exception. Out of 233 recoveries under its use, in but 22 had he seen the disease last less than two weeks, or from 9 to 13 days, a proportion of 9 to 10 per cent., and the average duration was 23 days. He relates a remarkable instance of this abortive action, not, however, as he says, to be imitated. A young man received on the sixteenth day of the disease, by mistake, an enema of one ounce and a half of carbolic acid, which was, fortunately, promptly expelled. In half

an hour he was in a state of collapse and coma, and the temperature fell from 104° to 95° F. The next day the rectal temperature was 98.6° F., and from this time it did not rise above 100.4° F. Recovery progressed, the typhoid process having been arrested.

Among other antiseptics employed in the treatment of typhoid fever, he mentions chlorine, iodine, sulphurous acid, the sulphites and hyposulphites, mercurials, oil of turpentine, creasote, thymic acid, benzoic acid, salicylate of bismuth, boracic acid, iodoform, resorcine, kairin, antipyrine.

Of the mercurials, calomel has been especially used, generally in large doses at long intervals. But Serres and Becquerel have administered continuously the black sulphuret internally, and externally by friction, although not to the production of salivation.

On the other hand, Dr. Salet, at the Hospital Saint-Germain, gave calomel in doses of 1.5 grains every hour until stomatitis was produced. Bouchard himself has collected 31 cases treated by this method, of which only 2, or 6 per cent., died. In those who recovered, the average duration of the disease was about 20 days. Two-thirds of the cases recovered in three weeks or less. In one-tenth of the cases, only, was the duration more than 25 days. Stomatitis was produced 18 times, on an average, after 9 days of treatment. In the thirteen cases in which stomatitis did not occur, the average treatment was about 10 days. The two who died were under treatment only 7 days, and the calomel seemed even in these cases to have exercised a favorable influence. The stomatitis was never serious, and disappeared rapidly under appropriate treatment.

Notwithstanding these favorable results, and that he believes calomel exercises a specific action and neutralizes the agent of infection, M. Bouchard admits that his own observations show that mercury diminishes the vitality of the patient, that convalescence is slow and tedious, that anæmia persists, and that strength returns slowly. He has also noted more frequent intestinal hemorrhages and dysenteric evacuations, and after recovery he has seen epistaxis, diarrhœa, pneumonia, and endocardial vegetations. Finally, he has found relapses more frequent—once in five cases. In a second series of cases in which he had used the mercurial subcutaneously, he found pneumonia and endocarditis less frequent.

As the result of these facts, M. Bouchard is not able to decide upon the practical utility of mercurials in the treatment of typhoid fever, but his clinical observations justify him in concluding that mercury, even in minimum dose, is competent to hold in check the development of the typhogenous microbe.

Antisepsis may, however, be advantageously used locally as well as generally. For nine years past, M. Bouchard has been in the habit of administering charcoal to his typhoid fever cases, not with a view to acting upon the typhogenous agent inhabiting the intestinal canal, since it is well known that putrefaction is not in the least affected by charcoal, but to absorb the product of the intestinal fermentations, and thus overcome the offensiveness of the intestinal contents. In this manner not only do the fecal matters lose their fetidity, but are made altogether inodorous, and furnish, on filtration, a colorless liquid. Thus, too, Bouchard believes that a large proportion of the alkaloidal substances known as ptomaines, which he discovered to be a constituent of normal fecal matter in 1882, and which are enormously increased in typhoid fever, are destroyed, and the toxic effect arising from their absorption avoided.

To secure antisepsis of the digestive tract, he combines iodoform with charcoal, of which ten grains are dissolved in three and a quarter ounces of sulphuric ether, and to this are added three and a quarter ounces of powdered vegetable charcoal. After evaporation of the ether, the carbon-iodoform is incorporated with six ounces of glycerine, thereby securing very minute subdivision and an enormous surface. Of the mixture, a tablespoonful, diluted with half a glass of water, is given to the patient every two hours. With a view to showing the effect of such a treatment, Bouchard ascertained that the injection into the veins of a rabbit of the extract of four and a half drachms of normal fecal matter per kilogramme of the weight of the animal produced death by convulsions in less than a minute. He injected in the same manner the extract of six and a half ounces of the fecal matter of a typhoid patient treated with the iodo-carbon, without any inconvenience whatever to the animal.

Under this treatment, he has seen the hospital mortality of typhoid fever fall from 20 to 10 per cent., and by the use of charcoal alone, to 15 per cent. In cases thus treated, also, he had noted the absence of odor in the intestinal contents of those dead of the disease, and a cleanness of the ulcers, which did not present the usual pultaceous appearance. The urine is less high colored. In lieu of the usual earthy complexion, the skin is remarkably clear, the tongue remains almost always moist, and bed-sores are extremely rare.

During such treatment, it is important to regulate the bowels in order to prevent accumulation of the charcoal.

As stated at the outset of this article, such results as these certainly demand a more thorough examination of this treatment, and justify the very modest conclusion of M. Bouchard, that while medical antisepsis has not yet secured all that has been promised, it has nevertheless realized some therapeutic progress.

Apropos of the above iodo-carbon local treatment, it is interesting to note that Bouchard has used it

in other diseases which are accompanied by excessive fermentation in the digestive canal, such as dilatation of the stomach, and putrid diarrhœa with or without ulceration. He has also resorted to it in cases in which fermentation is normal, but in which oliguria or renal impermeability prevents the sufficient removal of the agents causing the toxic effects known as uræmia, but which, according to his views, deserve rather the term stercoræmia.

CHOLECYSTOTOMY AND CHOLECYSTECTOMY.

In the issue of The Medical News for December 20, 1884, we presented our readers with a summary of the existing state of our knowlege of cholecystotomy and cholecystectomy. Of 27 examples of the former operation, analyzed at that time, 6, or 22.22 per cent., perished, while all of the 4 cases of excision of the gall-bladder recovered. The conclusions at which we arrived were, first, that in the operation of incision the use of sutures was dangerous on account of the periodical filling and emptying of the gall-bladder, and the risk of the escape of its contents into the peritoneal cavity; and, secondly, that, in view of the comparative safety of cholecystotomy, extirpation of the viscus exposes the patient to a needless risk, and that it should, therefore, be abandoned.

In the few weeks that have elapsed since the appearance of the article referred to, additional recorded examples of both procedures tend to show that these objections are not so weighty as we had supposed them to be at the time at which they were framed. In the case of Meredith, quoted by Morris in the *International Encyclopædia of Surgery*, Vol. V. p. 1073, the incision was closed with sutures and the organ returned into the abdomen. At the post-mortem examination, death having ensued in forty-eight hours from suppression of urine, the gall-bladder contained nearly a half pint of thick bile, and the duodenum contained a considerable quantity, thereby showing that the periodical filling and emptying of the organ had exerted no effect whatever upon the stitches. Hence, we may conclude that the objection has no foundation in fact.

In the *Berliner klinische Wochenschrift*, Nos. 51 and 52, 1884, Langenbuch records 2 additional examples of cholecystectomy, making 5 in all that he has performed. In the fourth case, an ulcerative perforation of the cystic duct close to its junction with the hepatic duct permitted the escape of bile into the peritoneal cavity, and caused the death of the patient. The existence of the opening was not suspected, as a thorough examination of the ducts was prevented by the presence of large masses of fat. The remaining cases recovered. Adding to these operations the 1 of Courvoisier, 6 cholecystectomies have yielded 5 recoveries, and 1 death, or a mortality of 20 per cent. 32 cholecystotomies, on the other hand, show 25 recoveries and 7 deaths, or a mortality of 21.87 per cent., and in three cases a permanent fistule remained. Hence, from a purely operative standpoint, extirpation is a slightly less dangerous procedure than incision.

In the present state of our knowledge it may be declared that neither operation is justifiable unless the common duct is patulous and icterus is absent. Under these circumstances, in recent cases, cholecystotomy should be resorted to; but should the coats of the gall-bladder be ulcerated, or should the viscus contain adherent connections threatening perforation, excision is indicated. In favor of the latter operation in all cases it may be mentioned that recurrence of the trouble is completely obviated, and that it does not appear to be attended with greater risk than does incision. For these reasons, a more extended experience may show that cholecystectomy is not so "intrinsically absurd" a procedure as Mr. Tait declares it to be.

EXTERNAL MIGRATION OF THE OVULE.

As is well known, the ovule set free by the rupture of the ovisac passes through the oviduct of the same side to the uterine cavity; thus, when the ovule is furnished by the right ovary it enters through the right oviduct to the uterus. But occasional cases were observed in which, for example, the recent corpus luteum was found in an ovary, the corresponding oviduct being obliterated, and hence the natural conclusion followed that an external migration of the ovule had occurred, by which it had passed over to the opposite oviduct, and through it had entered the uterus.

Experimental proof has recently been given of the truth of the hypothesis just stated. Dr. Buzzi, (*Annales de Gynécologie*, January), wishing to study extrauterine pregnancy, tried to produce this result in ten rabbits upon which he experimented. He removed in some cases the ovary of one side, and tied the abdominal end of the oviduct of the opposite side; in others he removed the ovary, and then tied and divided the uterine end of the oviduct. Of course in the latter case, supposing the left ovary to have been removed and the oviduct tied and divided, the spermatozoids might pass through from the uterus to this opening, and thence in the abdominal cavity to the right ovary. He hoped by the difficulties thus put in the way of the migration of spermatozoids and of ovules to cause an extrauterine pregnancy. The animals were placed with a male, and after some months one of them had young, and it was then killed. Examination proved that the ovules impregnated came from the right

ovary, though the right oviduct had been tied and divided, as has been stated, just at its entrance into the wall of the uterus. Further, the impregnated ovules had gained the uterine cavity through the left oviduct. The proof thus given of the external migration of the ovule is conclusive; it cannot be invalidated by the possibility, which has been suggested in regard to the ovule in the human subject where such migration was alleged, that the obliteration of the oviduct occurred after impregnation.

THE BACILLUS OF TYPHOID FEVER.

In his paper on "The Antiseptic Treatment of the Acute Infectious Diseases," read before the Eighth International Congress, at Copenhagen, M. Bouchard describes a bacillus, the study of which he has pursued for five years, and has found in all the pathological new formations occurring in connection with typhoid fever, except the sudamina. He considers this microbe to be the causal agent of the disease, although he admits that he has been unable to prove this with certainty, because, having introduced it into the digestive tube of the guinea-pig, the rabbit, dog, and pig, he has never been able to induce a disease similar to typhoid fever, while the morbid conditions he was able to provoke did not secure immunity from the true disease.

The microbe is easily cultivated in bouillon; its proliferation is prevented by the biniodide of mercury in the dose of one-third of a grain to the quart of bouillon, while half a grain is necessary to arrest the multiplication of the bacterium which produces spontaneous alteration in bouillon.

REVIEWS.

Sixth Annual Report of the State Board of Health of Illinois. With two Appendices: A.—Conspectus of the Medical Colleges of America. Revised to December 20, 1884. B.—Official Register of Physicians and Midwives in Illinois. Revised to December 1, 1884. 8vo. pp. xxiv. 103, xxvi. 96, xv. 324. Springfield, 1884.

This useful volume, in addition to the report of the Proceedings of the Board, contains much valuable information, going to show the absolute necessity of some supervision of the practice of medicine in the States; it contains a conspectus of the Medical Colleges of America, revised to December 20, 1884, and preceded by an admirable Review of Progress in Medical Education. The conspectus contains the title, location, address of corresponding officers, organization, curriculum of study, requirements for admission and graduation fees, number of matriculates and graduates of all medical schools in the United States and Canada, whether existing or extinct, regular or irregular, fraudulent or honest. This list is simply invaluable to any one who has to do with Medical Colleges. For nowhere else is so much valuable, well-arranged information contained in so small a space.

In addition, the volume contains a complete list of physicians and midwives to whom certificates have been issued since the organization of the State Board of Health, as well as of those whose licenses have been revoked, so that it is an official list of the practitioners of the State of Illinois.

SOCIETY PROCEEDINGS.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, January 27, 1885.

The President, R. F. Weir, M.D., in the Chair.

Dr. W. T. Bull read a paper entitled

A SUCCESSFUL CASE OF LAPAROTOMY WITH ENTERORRHAPHY FOR GUNSHOT WOUND OF THE INTESTINES.

(See page 171.)

Dr. Sands considered Dr. Bull's case to be one of great value as a contribution to abdominal surgery, and as calculated to encourage a resort to operative measures in the treatment of penetrating gunshot wounds of the abdomen. Of course, it was desirable to avoid abdominal section, if possible, in desperate cases, and in cases in which spontaneous recovery seemed probable. In Dr. Halsted's case the operation was not undertaken with much hope of saving life. The most important question relating to practice is, How shall the doubtful cases be excluded? The evidence of penetration of the intestine is in most cases uncertain. In very few instances, so far as his experience and knowledge went, even where the intestine was perforated, was there a demonstration of the fact, by an escape of feces or intestinal fluid from the opening in the abdominal wall. Dr. Bull, in his case, does not seem to have satisfied himself by probing, that the bullet had even entered the abdominal cavity. On the other hand, there are some cases in which there is reason to suspect that a bullet has perforated the hollow viscera within the abdominal cavity, but in which some doubt is afterward felt on this point, in consequence of the prompt recovery of the patient. Dr. Sands would like to ask Dr. Bull, What symptoms convinced him that his case was one of perforation of the intestine? If, in doubtful cases, this point could be settled, it might be the duty of the surgeon, in the light of the success obtained by Dr. Bull, and in view of the almost uniform mortality of such injuries, to open the abdomen, a procedure which might afford the only means of saving life.

Dr. Bull thought it was generally acknowledged that it was impossible to name any particular symptoms which indicated positively that the intestine had been wounded. It had been stated by authors that if there was general tympanites, and blood escaped by the rectum, one could infer that the intestines had been wounded; a large number of authorities had stated that there was no way to determine whether or not the intestines have been perforated. Dr. Parkes, of Chicago, in a paper read before the American Medical Association, in which he detailed the results of a series of experiments performed on animals, stated that as a result of his experiments it was impossible to form any con-

clusions from the symptoms as to the direction in which the bullet went, and also as to the amount of damage which it may have done, except within certain limitations. Dr. Bull thought it not right to say that in the absence of symptoms the intestines are probably uninjured. These considerations, and the fact that in this man's case it was uncertain whether the wound entered the cavity of the abdomen or not, led him to explore the bullet wound first, and when it was found that the wound did enter the cavity, the abdominal section was made. It seemed to him that the difficult question was not so much what kind of cases are we to operate upon, as what kind of cases is it not desirable to operate upon. Dr. Halsted had mentioned a case, which was a very desperate one from the first, but, at the same time, it was one of those cases which would certainly terminate fatally without interference, and he thought interference in such cases was justifiable, if there was prospect that the patient could sustain the operation. This was difficult to determine. Therefore, given an abdominal wound, with the patient in good condition, without any symptoms which enable the surgeon to determine whether or not the intestines have been perforated, he believed it proper first to explore the wound, and if the wound was found to enter the peritoneum, also to enter the peritoneal cavity by operation, and endeavor to remedy the damage done.

Dr. Stimson asked if laparotomy had ever been successful after feces had been extravasated into the abdominal cavity.

The President was under the impression that such cases were on record. He also remarked that it was difficult to form an opinion with reference to the amount of damage done in cases in which the symptoms of collapse were very marked, as in Dr. Halsted's case. The second case reported by Dr. Bull was one in which he assisted the operator, and also in deciding the question as to whether or not the operation should be performed, and he readily recalled the difficulty in reaching a conclusion as to whether the shock came from injury of one of the viscera or whether it came from hemorrhage. He thought it utterly impossible to determine this question positively, and believed it to be justifiable to make an exploratory incision, and to examine with the fingers, or, better still, in cases of suspected hemorrhage, to introduce a small sponge attached to a sponge-holder.

Dr. Sands inquired of the surgeons of the Presbyterian Hospital, who might be present, as to the exact nature of a case in that institution which was supposed to be one of perforating wound of the stomach, and which recovered without operation. If it could be proved to have been a case of perforation of the stomach or intestine, it would show that nothing could have been gained by surgical interference. He thought it impossible at present to formulate our experience so that it would enable us to determine positively when to operate.

Dr. Stimson thought it possible that a ball of small calibre could perforate the stomach without causing an escape of the contents of the stomach into the peritoneal cavity.

Dr. Briddon remarked that there was a class of cases in which it was doubtful whether or not the operation of laparotomy should be performed, and one question to be decided was, whether perforation of the intestine had taken place. At one time he regarded shock as a very important symptom in deciding this point, but had subsequently given it up, inasmuch as the condition of shock varied so greatly in different individuals.

Dr. Bull said that, in the class of cases referred to by Dr. Briddon, if the intestines are not found perforated after an exploratory incision, he would not consider that the patient's chances had been very much impaired by the operation. If the gut is not damaged, no special harm will be done by making an exploratory incision, and if it has been perforated, there are many chances in favor of recovery after the operation. He thought that his attempt in the case which he reported was influenced by the history of a case which he saw four or five weeks before his patient came under his observation.

It was that of an Italian woman, 35 years of age, who was shot in the belly, the ball entering just below and to the left of the umbilicus, and in which there was no more evidence of damage done to the contents of the abdominal cavity than in the patient upon whom he operated. For a week no one was able to say whether or not the woman had peritonitis, but gradually symptoms increased, and she had well-marked suppurative peritonitis. An abscess formed near the umbilicus, and extravasation of feces took place, secondary hemorrhage with the loss of only about two ounces of blood occurred from the epigastric artery, and the patient died. At the autopsy it was found that the intestine had been perforated by the bullet at only two places; one in the sigmoid flexure, and the other in the ileum. As soon as he learned the result of the autopsy, it occurred to him that there were but two wounds of the intestine, and that the patient was in good condition when she entered the hospital; and that abdominal section with such trifling lesions to deal with would have offered every chance of success. If he should see such a case to-morrow, he should feel that the best advice which he could give would be to have an exploratory incision made.

Dr. Bull thought that if members present would recall autopsies in cases of gunshot wounds, they would find that the number of perforations in some of them had been very small, and also that it was doubtful if a case of recovery could be recalled in which there was undoubted clinical evidence of intestinal perforation.

Dr. Sands said that, in cases like those mentioned by Dr. Bull, he should feel strongly inclined to follow the practice which he adopted. In the case of Dr. Hinton's, in the Presbyterian Hospital, the bullet, which was a small one, entered from behind, and it would have been almost impossible to follow its track through the tissues which it penetrated, but where the wound was in front, it could be readily explored, and the operative procedure adopted by Dr. Bull would doubtless commend itself as judicious. He should be disposed to operate promptly in such cases as these, as a preventive measure, rather than to perform laparotomy in cases in which the patient was apparently in a hopeless condition.

Dr. Markoe said that, on the other hand, it was but right to take up the opposite view of the question. He remembered a patient who was brought into the New York

Hospital some years ago, a sea-captain, who had received a pistol-shot wound while attempting to suppress a mutiny. He was standing upon the rail of his ship, and the mutineer was below him, so that probably the bullet entered the abdomen from below upward; it entered upon the left side, midway between the umbilicus and the superior spinous process of the ilium. The patient was brought to the hospital, after considerable delay. There was no evidence of fecal extravasation or hemorrhage, and the shock was moderate. The patient was in exceedingly good condition. Peritonitis and death, however, were expected, but the case progressed from day to day without the development of peritonitis, and the patient recovered without a single bad symptom. To be sure, it may be said, and it was said at the time, that it was a case in which the ball had evaded the hollow organs, and had slipped off somewhere to one side and become encysted, and who could settle the question, whether or not the internal organs were wounded? He simply mentioned the case because it was only fair to have both sides of the question presented.

Dr. Sands said that the case mentioned by Dr. Markoe, recalled to him one in which a bullet was found encysted in the great omentum in the body of a dissecting-room subject. When the bullet was discovered, a further examination was made in order to determine, if possible, the course it had followed, and a cicatrix was found in the back over one of the lower intercostal spaces on the right side. There were also found adhesions between the opposed pleural surfaces, a cicatrix in the diaphragm, one on the upper and another on the under surface of the liver.

The President referred to a case which he saw during the war, in which there was found a lodgement of a bullet in the omentum, where it hung suspended in the abdominal cavity. He also remarked that the cases of gunshot wounds which presented themselves in our civil hospitals were made at short range, and that experiments conducted on many cadavers in the late war showed that in nearly every instance such wounds involved the solid or hollow viscera. While opposing the usual ostrich principle and advocating a bolder treatment in penetrating gunshot wounds, he thought that Dr. Bull had laid too slight stress upon the danger of exploratory incision. He had been struck with that fact in laparotomies for intestinal obstruction done by himself and witnessed in practice, where the exploration necessitated the taking out of the entire intestines in the hunt for the point of obstruction. He had not yet seen a case in which such a general overhauling of the intestines had been followed by recovery, and he, therefore, thought it well to distinguish between exploration of the peritoneal cavity and exploration of its contents.

For some time past, with regard to Neuber's intestinal plug, to be in readiness for a case of intestinal obstruction, he had provided himself with several large-sized gelatine vaginal suppositories, also with several pieces of the largest sized macaroni, to be used singly or in bunches, and also sections of the finger rolls, used at dinner, were at times put into the intestines to stitch the gut over and allow them thus to remain in situ to be subsequently dissolved. He had not, however, had opportunity to use any of these articles. Freres's rubber bags, which he had shown at a previous meeting of the Society, were easily collapsed by an incautious puncture of the needle.

Dr. Lange remarked that, interesting and instructive as Dr. Bull's case was, it admitted the question whether in this individual instance the patient's life could not have been saved without the operation. At the time of the operation the patient was in a fairly good condition; there was no evidence of peritonitis, and the patient's general condition was such, seventeen hours after the injury, as to render it exceedingly probable that no extravasation of the contents of the gut had taken place. He would like to ask Dr. Bull if, taking into consideration the condition of the parts injured found at the operation, the closure of the small wounds by apposition of gut and fibrinous deposits, and the nature of the exudation, if he would regard the recovery of this patient as improbable without operative interference? Second, he would like to ask if Dr. Bull thought it possible that, a number of injuries of the intestine being present, there might have been some probability that manipulations of the gut could have reopened some of the bullet holes, and allowed infection of the peritoneum to take place in consequence of the operation itself.

His remarks did not in the least diminish the value of the operation so far as it was an exploratory operation, but the question was, What had the operation afforded? What did it do? The operation cleaned the peritoneal cavity, it is true.

Dr. Lange thought that the indications for an exploratory operation were far more clear in cases in which a short time after injury the symptoms of peritonitis were present than in those in which they were absent, for such a length of time as in the case reported by Dr. Bull.

Dr. Bull replied that it was impossible to answer whether or not the wounds would have remained closed. Where so many wounds had been made in the intestine, even if no fecal contents escaped at the time of making them, a sufficient amount of irritation would be produced to give rise to peritonitis; and, moreover, the liability of foreign matter being introduced by the bullet, which would produce damage entirely independent of the wounds of the gut. He would say that in a patient with seven wounds in the intestines there were next to no chances of recovery by any conservative plan of treatment.

Dr. Briddon asked if eversion of the mucous membrane did not interfere with the process of repair, if the wounds were left alone.

Dr. Lange replied that it did so far as the mucous membrane extended, but he did not see why the peripheral part might not be closed.

Dr. Briddon remarked that mucous membrane would not unite with the peritoneal covering, and if left to themselves, would not small abscesses form at the site of eversion?

Dr. Lange replied, not necessarily.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Friday, January 2, 1885.

The President, Richard A. Cleemann, M.D., in the Chair.

DOUBLE UTERUS AND VAGINA.

Dr. Wm. Goodell described a case which had been sent to him on account of pain in the back, various

nervous symptoms, and difficult coition. The vagina was double throughout its entire length. Entrance had apparently been effected indifferently on either side of the septum. The cervices were united like the barrels of a double-barrelled gun. There was a slight divergence of the upper third of the fundus. The sound entered three inches into each cavity. The septum vagina was divided up to the cervix, and her physician reports great relief to the general symptoms.

Dr. C. McClelland described a similar case. Pregnancy had progressed to the third month when the case came under his observation. The vaginal septum was complete. The external contour of the cervix was normal, but the septum, extending from the os to the fundus, divided the cavity into two parts. The prominence of the uterus was greater on one side of the abdomen. The sound was not passed. The vaginal septum was divided shortly before labor. A living child was delivered. About the third day after delivery, a mass, apparently of decidua, was thrown off after three or four hours of labor pains. After involution was complete, sounds were introduced into the uterine cavities, and the handles diverged one and three-fourths inches. A second conception occurred afterward on the other side of the uterus.

Dr. Goodell some years ago had under his care a case which he at first diagnosticated as an extra-uterine pregnancy, as he apparently found the uterus empty, passing the sound into it, while undoubted signs of pregnancy existed. The fœtal tumor was larger toward one side of the abdominal cavity, while the uterus was deflected to the other side. He saw the patient every two weeks, and made frequent careful examination. He sent the patient to the University Hospital, and fixed a day for operation. One day, while lecturing on the case, he had his hand on the abdomen of the patient, and felt a contraction and hardening under his hand. This so resembled the action of uterine tissue that he sent the patient to the Preston Retreat for observation. She was delivered spontaneously.

There was but one cervix and one os, but there was a uterine septum higher up, dividing the cavity into two parts.

Dr. Harris remarked that the observer, in these cases, is liable to be deceived because the enlargement of the uterus causes it to rotate, the empty half of the uterus admitting the sound in the median line. The uterus, too, is generally poorly developed, as this form of uterus is probably the result of arrest of development, and its thin walls do not give, to the palpating hand, the normal sense of thickness and resistance.

DOUBLE OVARIOTOMY, WITH UNUSUAL COMPLICATIONS.

Dr. W. H. Parish reported the following case: In September, 1884, I saw, in consultation with Dr. M. O'Hara, a lady who had been under his treatment for a number of months. She was 52 years of age, and of exemplary habits. The menopause had been established for a number of years, and she had enjoyed good health until a few months ago. In June, 1884, she noticed, for the first time, that her abdomen was enlarged. In July she consulted Dr. O'Hara, narrating symptoms of indigestion. In August the abdomen had become so enlarged as to occasion concern on the part of the patient, and she had submitted to an examination by Dr. O'Hara. About August 15 Dr. De F. Willard saw her, in consultation with Dr. O'Hara, and the diagnosis of ovarian tumor was coincided in. On September 6 I saw the patient with Dr. O'Hara, and also diagnosticated ovarian tumor. The physical signs were the usual ones characteristic of ovarian tumor. There was distinct resonance in each flank, and no indication of fluid in the peritoneal cavity. The abdominal distention had become very considerable, occasioning no little interference with respiration, and was associated with slight œdema of the lower extremities and general emaciation. Removal by operation was urged upon the patient, but was positively refused. After the lapse of ten days I again saw her with Dr. O'Hara. The difficulty in respiration had so greatly increased as to prevent sleep, except in the semi-erect position. But little nourishment had been taken, and exhaustion had correspondingly increased. In the erect position the pulse was 160 per minute; in recumbency, 130. The abdomen measured forty-five inches at the umbilicus. Its shape had changed since my previous visit. In the flanks there was distinct bulging, with fluctuation and percussion dulness. I diagnosticated peritoneal dropsy as a complication of the ovarian cyst. The œdema of the lower extremities had increased. The patient had requested that she be tapped, and it was with reluctance that I consented to resort to that measure. On September 14, with the assistance of Drs. O'Hara and J. B. Roberts, I attempted to diminish the size of the abdomen by tapping the cyst, using for that purpose the ordinary trocar and canula. Only a few drops of thick gummy substance were obtained. The cyst contents were too thick, too jelly-like, to run through the canula. But a single puncture was made. The patient now gave her consent to the performance of ovariotomy.

September 16.—The patient has been fed and stimulated as her condition demanded or permitted. Pulse 120; resp. 40; temp. 98¾° F. As yet no apparent disturbance from the tapping.

17th.—Pain referred by the patient to the bowels; three movements, probably resulting from indigestion.

18th.—Operation performed; previous to the operation, pulse 130; resp. 40; temp. 99° F. Tongue dry and brown. Bowels moved twice during the night. Still has pain, supposed by the patient to be in the bowels. There were present: Drs. O'Hara, A. H. Smith, J. B. Roberts, and McElroy. The patient was etherized by Dr. Roberts, and the usual incision along the linea alba was made. The tumor was found to be adherent to the anterior abdominal wall. An attempt was made to break up these adhesions, but the cyst-wall was so extremely thin that the cyst was soon torn into. Its contents were too gummy to flow, and it was necessary to scoop out this substance with the hand. The contents had the consistence and appearance of calf's-foot jelly, and was adhesive like gum, sticking to the hand so that it was necessary to strip it from one hand with the other. There were numerous slight adhesions to the intestines, but as the cyst-wall was so extremely thin, these adhesions were not troublesome, portions of the cyst-wall being left attached to the intestines. It was soon discovered that the cyst-wall had ruptured prior to the operation, and that every portion of the peritoneal cavity contained quantities of the colloid material and masses of dark grumous blood. The contents had doubtless

escaped gradually from a rent in the upper posterior portion of the cyst several days before the tapping. It was the presence of this material in the peritoneal cavity that led me to diagnosticate the coexistence of peritoneal dropsy. There was no serum in the peritoneal cavity. Washing the peritoneal surface with water would not remove the colloid material, and it became necessary with hand and sponge to remove it from the under surface of the liver, from about the spleen and kidneys as well as from among the intestines. After emptying the large tumor, it was discovered that there was a smaller one about the size of a fœtal head, unbroken and without adhesions, and partly pressed into the pelvis by the superincumbent large one. The two tumors presented the same characteristics. They had thin transparent walls with numerous internal alveolæ and thin septæ, with gummy colloid contents. About the base of each, but especially of the larger, there was a limited amount of solid substance. The pedicle of each was ligated and dropped into the abdomen. Each tumor evidently grew from an ovary. The general peritoneum, wherever it could be seen or felt, presented innumerable cysts with walls and contents like those of ovarian cysts. These peritoneal cysts varied in size from that of a millet seed to that of a pea. Many of the larger ones were ruptured by the hand or sponge. These minute cysts were not arranged in clusters with stem-like attachments to the peritoneum, but were isolated, and had the appearance of blebs on the peritoneal surface. The peritoneum presented general injection of its capillaries, with slight roughening of its surface, but there were no evidences of active or decided peritonitis. The hemorrhage was but trifling, and but few ligatures were applied. The abdominal incision extended about an inch above the umbilicus. A glass drainage-tube was introduced at the lower angle of the wound, and the remainder of the incision was closed with silver sutures. At the close of the operation, shock was not great; pulse 134. Morphia was given, and the patient passed a somewhat comfortable night. No vomiting.

19th.—Morning, pulse 138; resp. 34; temp. 100° F. Evening, pulse 140; resp. 30; temp. 102° F. Vomited a little, and abdomen somewhat distended. Face pale, and features pinched. Three ounces of pinkish serum removed from tube. Vomiting checked by swallows of hot water, and a mixture containing creasote and sodii bicarb. Tube washed out with carbolized water.

The third night the patient was restless, and vomited. Next morning, pulse 150; resp. 26; temp. 101¾°; increased stimulants, and at noon pulse was 138; resp. 26; temp. 100⅗°. Fourth night, slept some, less vomiting; she takes koumiss, and retains it. Next morning, pulse 140; resp. 20; temp. 100 4/10°. Fifth night, pulse 120; resp. 22; temp. 101⅘°, stronger. Three ounces of a somewhat offensive fluid were taken from the tube; bowels were moved spontaneously. Sixth night, she slept well; pulse 114; resp. 23; temp. 101⅕°; sutures removed, union complete. Tube slipped out, and could not be introduced again. It left a canal with healthy granulating walls. Seventh night, vomiting returned; she did not receive the usual amount of stimulants during the night. Exhaustion and vomiting increased, without additional rise of temperature, and patient died on the ninth day. The death was doubtless due to exhaustion. The disease of the ovaries and of the peritoneum was doubtless colloid cancer. The tumors and the material removed from the peritoneal cavity weighed fifty pounds. It seems right to conclude that had the tumors been removed in their earlier stages, the patient would have most probably recovered from the operation, and have remained exempt from the disease for months or years, or perhaps permanently.

Dr. Montgomery spoke of the advantages of early operation before peritoneal involvement. He also alluded to the dangers of tapping. He gave a short history of a case of ovariotomy with colloid contents, and recovery from the operation, but followed by death six weeks later from cellulitis and ascites, the cause being unknown.

Dr. Baer related a somewhat similar case, in which the patient recovered, but is now apparently dying from a recurrence of the disease in the upper part of the abdomen.

Dr. Parish, in closing, said that the tapping was done with reluctance, but did no harm in this case. The peritoneal complication made the case hopeless.

OFFICERS FOR 1885.

President.—B. F. Baer, M.D.

Vice-Presidents.—E. E. Montgomery, M.D., W. H. Parish, M.D.

Secretary.—W. H. H. Githens, M.D.

Treasurer.—Alfred Whelen, M.D.

Librarian and Curator.—T. Hewson Bradford, M.D.

Council.—Wm. Goodell, M.D., R. P. Harris, M.D., T. M. Drysdale, M.D., L. D. Harlow, M.D.

Publication Committee.—J. H. Packard, M.D., B. F. Baer, M.D., J. C. DaCosta, M.D., J. B. Walker, M.D.

Library Committee.—Horace Williams, M.D., D. Murray Cheston, M.D.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 5, 1885.

The President, Fordyce Barker, M.D., LL.D., in the Chair.

The Statistical Secretary, Dr. F. V. White, announced the

DEATH OF DR. JAMES OWEN WHITE,

on January 30th, of disease of the kidneys, in the eighty-third year of his age. He was born at Coxsackie, Greene County, N. Y., and graduated at the College of Physicians and Surgeons, New York, in the year 1825 He had been a Fellow of the Academy since 1853.

The President then introduced a number of

DISTINGUISHED VISITORS,

including Drs. John S. Billings, U. S. A., of Washington; S. Weir Mitchell and Theophilus Parvin, of Philadelphia; and George B. Shattuck and James R. Chadwick, of Boston. The venerable Dr. James Anderson, one of the ex-Presidents of the Academy, and Prof. Alfred C. Post were also invited to take seats on the platform.

The President, Dr. Barker, then delivered a *Valedictory Address*, after which he resigned the Chair to

the PRESIDENT-ELECT, DR. A. JACOBI, who then delivered his

INAUGURAL ADDRESS.

After expressing his thanks for the honor done him, and his appreciation of the responsibilities of his position, he alluded to the brilliant qualities of his predecessors in the Presidency, and said that the only thing that reconciled him to accepting that position was the flourishing condition in which they had left the Society. Having again expressed his thanks for the honor conferred on him, he made the request that every Fellow would consider the interests of the Academy under his personal charge.

He described the Academies of Medicine in Europe, which were made up of a few men who were preëminent for their achievements, each in his special department, and said that the New York Academy was of a more democratic character, and it was desirable that the many reputable practitioners should gather round its flag. Like the Union, it is a voluntary confederation, who make their own laws, and obey them, because they are of their own making. Almost all were men busily engaged in active practice; none devoting themselves entirely to study alone. Anglo-Saxon medicine has never forgotten that the aim and end of all medical science are the treatment and treating of the sick, and that every special study is but a means to obtain that end.

In New York, he said, there were too many societies, too much subdivision, and it would be better that the profession should concentrate its energies more in the prosecution of scientific work. All the various special societies, he thought, might well have been sections of the Academy of Medicine, as they could still have remained practically independent organizations.

The practical tendency of this Academy, he said, corresponds with the peculiar practical nature of the development of medicine in the English-speaking nations from the last century onward. Even the most fragmentary study of that development is of great interest indeed. Altogether, medicine in the eighteenth century exhibits a peculiar character. It is true that knowledge was not widespread, but the heads of the profession were capable, painstaking, searching, cool-headed men, good observers, and excellent describers. There was a large number of good monographs, excellent histories of cases, and fair diagnoses of the general condition of the patient. Local diagnosis, it is true, was mostly out of the question, since no sooner than in the second half of that century Morgagni collected in his illustrious work, *De Causis et Sedibus Morborum*, all of the only three thousand post-mortem examinations which had ever been recorded in all ages and countries. Their judgment was sound, their therapeutics—though often exuberant—safe. As the scientific language of most of them was the same, Latin, their spirit was not local nor national. The same class of men were found in Germany and the British possessions; also in Holland and France. In the former, we meet the names of Werlhof, R. A. Vogel, Zimmermann, Lentin, Van Swieten, J. P. Frank. There was also Auenbrugger, who ought not to have been so readily forgotten. In Great Britain there were Mead, Huxham, Fothergill, Pringle, Heberden, Monroe, Home. Cullen, there was that giant John Hunter. In America, we had Bard and Rush. In France, Levret. In Holland, at an early date, Boerhaave. The only fanatical theorist of all the English writers was John Brown; the only obscurist, who ought to have had a place in Germany between 1800 and 1840, was Robert Jones, with his *Inquiry into the State of Medicine on the Principles of Inductive Philosophy* (1782). When Broussais reigned supreme in France, his doctrines were welcomed by a great many in England. But the Anglo-Saxon mind is not easily drawn away by theories, and there is after all more solid work in Broussais than wanton theory only. Thus the English literature of the early part of this century teems with good observations and monographs by many more than those I here mention—Travers, Williams, Crawford, Astley Cooper, Brodie, Bell, Abercrombie, Cheyne, Pitcairn, Bright, Hope, and Carswell.

Of French names I have mentioned but one.

The redemption of France, after a century of almost unparalleled corruption and misery, begins with its great Revolution. Never before did fate grant to an unhappy nation a larger number of great spirits, both in politics and science. The faint impression the freer institutions of the British Island made on French literature would not have influenced the development of the country for centuries to the same extent as did the necessities of the population. In the history of political and mental development changes more or less sudden or gradual appear to be the rule; rise and decline change off, as the fertility and sterility of a corn-field. The fertility of France lasted a long time. While the greatest man in its political world could not do better than spread all over Europe part of the results of the French Revolution, through violence and murder, a young scientist revolutionized medical science by genius and hard work. That is what Bichat did when he studied the physiology and pathology of the organic tissues. Since that period, France has marched at the head of medical science for about half a century. Pinel, Corvisart, Cruveilhier, Biett, Cazenave, Gibert, Laennec, Ricord, Civiale, Guérin, Guislain, Baillarger, Leuret, Longet, Guersant, Taupin, Valleix, Legendre, Dupuytren, Trousseau, Rilliet, Barthez, Durant-Fardel, Orfila, Louis, Broussais, Piorry, what a host of illustrious names, and by far not the only ones who will recall the glory of the French nation when there will be no longer a political France. It is true that a decline has set in. The number of really great men in modern French medicine is but limited. Charcot's name overshadows the reputation of all others, and, it appears to me, will live for centuries. It may be also that Pasteur will be recognized as a fixed star in the scientific sky if he will succeed in divesting himself of the doubtful attributes of polemical tendencies.

After Bichat there are three French names connected with the history of medical sciences in all countries. Laennec's revolution of diagnosis by percussion and auscultation, is not any the less important and precious because Auenbrugger had worked in the same field more than half a century previously, to no other purpose than complete oblivion. Magendie's experimental physiology and pharmacology have benefited all mankind. His is the introduction of alkaloids, such as quinine, veratrine, strychnine, piperine, morphine, emetine—his, the successful admission of bromine and

iodine into practical therapeutics. Finally Broussais, by overthrowing ontologies—though he created one of his own—by localizing disease, by urging prevention and abortive treatment, by studying the anatomical lesions of pathological processes, has substituted a method of anatomical thought in diagnosis for the merely clinical and empirical observation of the sick, and thus been the intellectual author of that method of medical knowledge and reasoning which is best known by the name of the Vienna school. I shall have to consider its representatives shortly, with all its virtues and faults, both of which were learned and loaned from the illustrious Frenchman. For not only did he convey to them his anatomical way of thinking, but he also taught them to be satisfied with coarse local anatomical lesions, and with a nominal diagnosis, adding the assurance that those lesions must lead to death; that indeed the case is either getting well spontaneously, or absolutely hopeless, and that a treatment of any kind is powerless.

The parallelism of political and scientific conditions which strikes us so admirably in the history of French development after the impulse given by the Revolution, is sadly illustrated by poor Germany. The country poor and forlorn, divided in hundreds of shreds, large and small, tyrannized and robbed by hundreds of dukes and bishops, and princelings of all sorts, every one the inferior in mind, but the emulating admirer of the tendencies of that despotic Frederick the Second, of Prussia, in whom it requires the equally despotic soul of a Carlyle to find nothing but admirable traits; that country had, about the end of the eighteenth century, one representative in medicine corresponding with the character of the time. Hufeland was a fair observer, a copious writer, an influential man, but weak and accessible to everybody and everything. It was he who admitted the first Hahnemannian gospels to his journal, and who was of the wise opinion that there may be something good in everything. Then came the French, and whipped the Germans out of political existence. Then the wars which expelled the French, bloody, costly, and short, aroused a peculiar romantic fanaticism which pervaded the whole literature of a short decade, and could but have an unfavorable influence on science. Then came decennia of brutal political reaction and suppression, the scanty means of the nation being spent on police, military, and dungeons, in which the flower of the country, and particularly of the universities, was incarcerated. During that time German thought had no place in terrestrial parts; even before that time Schiller had proclaimed man "free though he wore chains." This sort of freedom the Germans utilized to become transcendentalists. The principal method of studying nature was imagination. Even Kant, the mathematical thinker, had taught them the art of construing things a priori. Then came Schelling with his system of natural philosophy, and Hegel who wrote twenty big volumes, and is reported to have said on his death-bed, that in all his life he had but one pupil who understood him, and that one did not know anything about him. Under the influence of these philosophical absurdities no medical science could thrive. This was the time of animal magnetism and granioscopical humbug.

In such a condition of universal intellectual semi-paralysis and revelry in big words and clouded sensations of all kinds, combined with the insensate and murderous character of therapeutics, it was natural that homœopathy could thrive, with its axioms, that disease was an enemy from without, the result of psora or of medicines; that nature was an enemy of man; that nature will not cure a disease, but a medicine will; that no medicine which can be shown by any physical or chemical analysis still to exist will cure; that its dynamical power increases with its attenuation and annihilation. That was the time in which one of the great lights of German medicine defined inflammation as the condition in which the "electrical essence (or part) is affected in the dimensions." Marcus never said that he understood that himself. At that time the medical literature of Germany was full of such philosophizing nonsense; full of contempt of the unphilosophical foreign countries; of Bright, with his British coarseness in studying nature as it was; of Laennec, whose percussion and auscultation were declared to be immoral and irreligious. My beloved teacher, Prof. Fred Nasse, though all his life a believer in and author on animal magnetism, was one of the first to utilize Laennec's great innovation and the lessons of foreign teaching. Even Schoenlein, though it was through his influence young Virchow, after he had been expelled from Berlin for his liberal political views, was called to Würzburg to teach pathological anatomy, could not free himself from the influence of philosophical doctrines. At that time the science of therapeutics consisted indeed in nothing but empty words, its practice to a great part in the traditional bloodletting, salivation, and purging. Thus it was that the fanatical hydropathists, and the adversaries of vaccination, could obtain such rare opportunities and successes. Thus, that but forty years ago, Rademacher could divide all ailments into saltpetre, copper, and iron diseases, by reason of the remedies of which each cured one-third of all the ailments of German kind.

Schoenlein and Liebig having prepared the medical minds, and the influence of foreign literatures being gradually felt in Germany and Austria, it so happened that Vienna had in its faculty of medicine quite an array of medical genius. Rokitansky, Skoda, Hebra, have long reigned supreme. Broussais's doctrines, good and bad, were readily accepted; his ontological gastro-enteritis was replaced by Rokitansky's doctrine of the crases of the blood, thus reëstablishing the old humoral theory on an apparently firmer foundation. In Rokitansky's opinion, the anatomical changes were the only thing in medicine worth knowing. Skoda, for some time, experimented carelessly and unsuccessfully with remedies; his ill-success and Rokitansky's teaching, confirmed the nihilism of Broussais against which Laennec protested in France, and made the expectative treatment, and the nihilistic faith, the gospel of German practice.

"This was the medicine—the patient's woes soon ended,
And none demanded: Who got well?
Thus we, our hellish boluses compounding,
Among these vales and hills surrounding,
Worse than the pestilence have passed.
Thousands were done to death from poison of my giving;
And I must hear by all the living
The shameless murderers praised at last."

But in Goethe's "Faust" this is said by an incorrigible philosophical roué, who is ready to give himself up to the devil, and in Germany it had the result that the public, who have a right to desire to be cured when they fall sick, preferred the homœopathic pill-box to the pathologist's post-mortem case.

Not long after, Oppolzer, whose name ought to be blessed forever in Prague, Leipzic, and Vienna, began his influential career. In him Germany possessed its first great physician in this century, who knew pathological anatomy perfectly, was a thorough diagnostician, a humane physician, an amiable teacher, who recognized the social, scientific, and humane duties of the practitioner, abhorred preconceived ideas and a priori constructions, acknowledged principles and facts only, and no duty but to find the truth.

It was about that time that Rudolf Virchow commenced to revolutionize medicine. Modern medical science owes its solid foundation and elaboration to him and his followers. The book of medicine of to-day, and, I trust, of the future, bears the imprint of his genius on every page. We all have read, and admired, and praised, knowing that when we readily place Germany in the first rank of the medical world to-day, the name of Virchow is in every mind, on every lip. This brief sketch cannot do him justice, nor do I desire to elaborate a theme with which every one is familiar. But one remark I cannot suppress, viz.: that he is not only great in his revolutionary discoveries and innovations, but in his self-denying conservatism also. If the bacteriomania of modern time has not been accepted uniformly as the universal gospel of modern pathology, if thoughtful hesitation and healthy criticism are still heard above the noisy waves of the seas of all-explaining and all-saving theories which claim to have given, at last, an absolutely solid base to etiology and pathology, that merit again belongs to a great extent to Virchow. I speak of it here because I hope that this Academy may be able to contribute to the solution of questions of great import, by original studies and discoveries.

For there was lately a time, or rather we still live in that time, when a single series of discoveries lays claim to having changed the aspect of pathology at one stroke, and solved all problems. You know I speak of bacteriology. In America also, all of those who cannot judge of the question by their own investigations—that is, the practitioners, either general or special, have readily accepted the new gospel with but few exceptions. The new theories that infectious and zymotic diseases have each their own bacillus, are so pleasant, and promised to be so fruitful, that it required some courage critically to resist the flood. On the other hand, those amongst us who have a right by their own researches and special knowledge to be heard, have hesitated to accept the results of microscopical, actual or alleged, discoveries as the sole explanation of everything infectious and zymotic. Amongst them I shall only name Wood and Formad, and Sternberg. Into the merits of the case, and the weighing of reasons I cannot go this evening, but it has appeared to me that it would be well to direct the attention of the Academy to that subject as one greatly deserving of its attention.

To me, while I readily acknowledge a valuable increase of pathological knowledge, and the fact that the spreading of some disease at least, slow, and gradual, and regular, seems to prove the multiplication of cases of disease by the regular multiplying of its causes, it has always appeared that purely bacteric etiology has too often begged the question, and that the answer to the question, whether organic or chemical poisons are the main causes of infectious diseases, has, by no means, been satisfactorily given. In the course of the last dozen years, organic chemistry has made as rapid strides as has microscopy. Cadaveric poisons, ptomaines, have been discovered in great numbers. Most of them are very destructive. Sudden deaths of zymotic and infectious diseases resemble much those produced by these poisons. That the stings of insects, or the poison engendered in putrid corpses lead to speedy destruction has always been known. Its symptoms are exactly like those produced by many known poisons. Forensic medicine has a great many instances already, in which it could be proven that the poison extracted from the body of the dead was not a vegetable agent, introduced during life, but the cadaveric poison. Count Gibbone was said to have been murdered with delphinine. Prof. Selmi proved that what was claimed to be that vegetable poison, was cadaveric. In another case, he saved the life of a suspected person by proving that it was not morphine, but a ptomaine which was found in the body. Besides the poisons named, there are strychnine, colchicine, atropine, coniine, woorara, nicotine, veratrine, hyoscyamine, narceine, the symptoms and chemical reaction of which are the same, or almost so, as the cadaveric poisons. Lecithine is found in putrid fish; a very dangerous chemical poison has been extracted from putrefying Indian corn and rye. Thus it is that many cases of poisoning with cheese, meat, fish, sausage, jelly, and yeast, many of them resembling acute infectious fevers, may find, and indeed have found, this ready explanation.

Brieger found quite a number of different varieties of cadaveric poisons—neuridine, neurine, muscarine, æthylendiamine, gadinine, and others. Many of these destroy life in a short time, and with the symptoms of acute infectious diseases. These poisons are found, in many instances, in the fresh dead body, not in that one which has undergone complete putrefaction. The results of putrefaction will, after a while, change entirely and become rather wholesome than injurious. Many years ago, Salkowski examined a vessel full of ascitic fluid, which he knew to be in utter putrefaction when he last inspected it. Not only was there no putrefaction any more, but, on the contrary, chemical decomposition had formed phenol. Thus putrefaction had worked its own destruction and antidote. The inference, then, is that a poison, even in the course of the same disease, may not always be found.[1]

[1] Would it be so impossible to judge that the bacterium is an accompaniment of a chemical poison and may be present, or absent, according to the changed condition of the poison? Such changes take place all the time in putrefying material as Salkowski has shown, and others after him. They probably take place in the living body also, during infectious fevers. In the incubation they develop, they are most poisonous and vehement during the height of the process, they gradually change into less dangerous combinations, into an indifferent state, and finally a really disinfectant

Ptomaines are often met with in the presence of bacteria. Is it the latter which produce them? Do they so decompose the albumen of the tissue that a ptomaine must or can develop? Or is it their own vital change which produces it? Most modern writers—not chemists—believe it. But if the cause of decomposition of the living or dead be not bacteria, but a chemical poison after all, is it necessary to assume that the poison cannot form except through and with the presence of bacteria? And is the bacterium the only poison? or the only source of the poison?

If deadly poison, such as we know to destroy life suddenly, or almost suddenly, and of such virulence as is reported in what was formerly believed to be legendary only, but which may be historical, will almost invariably originate in the dead body, is it so impossible that it may develop in the still living under certain circumstances? Have we not had enough yet of the monthly instalments of new bacilli which are the invariably correct and positive sources of a disease, and replaced by the next man who comes along? Have we not yet enough of the statements, that, as for instance, several bacilli are claimed each to be the only cause of diphtheria, by several observers, that there may be several distinct bacilli, every one of which can produce the same scourge? Is it not just as safe still to presume, that, when several forms of bacilli are believed to be such sole causes, that the real cause is in neither?

Exactly so, neither in one nor in the other, notwithstanding it all appeared settled. For our journals are replete with the very latest authentic baterium of diphtheria. This time it is neither Klebs nor Eberth, but Loeffler. Reports, discussions, and even editorials carry his name over the world. The very nature of diphtheria is said to be revealed again, as several times before; still, the discoverer admits that there are cases without the bacterium.

The matter is becoming ludicrous. I begin to fear something like the rebellion against piano-playing in a large European city. Is not music a godly art, and the piano a blessing to the musician? But the playing of fifty thousand beginners in a large city is a nuisance. When bacterio-microscopy in the hands of beginners becomes noisy like piano-playing—noisy in books, pamphlets, and journals—a gentle protest is permissible. That protest is not meant for the masters who know how to wait and to mature. I do not speak against Robert Koch and his peers, who all of them are more modest than their followers. When the kings build, the cartmen are kept busy—and boisterous.

A dozen years ago the coccus of whooping-cough was said to be discovered. There was no doubt about it. There was whooping-cough, there was a coccus, what was plainer and more conclusive? To cure whooping-cough, nothing is required but to kill the coccus. Quinine will kill a coccus, quinine cures whooping-cough. Since that time there is no more whooping-cough in existence; or, if a case would be malevolent enough to turn up, it could not last longer than until a few whiffs of quinine can reach it. That is ludicrous, is it not? But it was preached like gospel, and it was believed. Many more such have turned up, and will turn up, for coming years to smile at.

There is a peculiar feature in this bacteriomania. Its principal impetus it received in Germany at a time when great changes had taken place in its political and financial affairs. All at once there was an Empire, of which historians so much spoke, youth so much dreamed, romancers so much fabulated. All at once, at the same time and a decade before, an unusual industriousness, commerce, enterprise, and unwonted wealth, and still more expectations than wealth; all at once an influx of five thousand millions of francs, not earned by honest work, but conquered by war, which could not but turn the poor heads and unstable the solid foundations of regular development. From that time dates the lack of safety and steadiness in German financial circles. They have even invented a name for that period of swindling, "gründerthum." Speculation was rife—fortunes were made in a day from nothing but self-assertion and daring, and lost as quickly.

The moral and intellectual atmosphere created by these tendencies is never breathed by one class of people only. If self-assertion can make a fortune in finance, why not in science? If a reputation may perhaps be made by a stroke of chance, why not try that chance? Speculation was rife. Any young man can look through a microscope, perhaps he will draw the prize in the lottery of alleged science. Looking would be all right, if he would not write. Medical life would be easier if there were less journal articles containing the latest infallible discoveries. Thus it has come to pass that German medicine has a twofold aspect nowadays. The days of her superiority are not over yet, her greatest men still live, and the toiling thinkers are at work, but the number of speculators is immense. A great many of the articles printed in the journals of the last ten years have been prematurely published, the number of preliminary notices announcing discoveries under way is very large. The great embryo cannot wait. He is afraid of having his celebrity snatched away from him by the next-door microscopist.

Thus it is that we often find a difficulty in keeping our eye on the great lights, whose rays are always welcome. If learned and thoughtful specialism has its justification anywhere, its field is the solution of the mooted questions alluded to. Thus far I claim, however, that in regard to bacteriology, the main questions are before the medical world still. I firmly hope the Academy will prove the centre of critical researches by which the problem, whether bacteric or chemical poison, still a mystery, will be carried nearer its solution.

In this expectation I am justified by a reference to the historical fragments you permitted me to sketch to-night. There has been no deviation from the empirical and clinical tendency of Anglo-Saxon medicine from the beginning. It was so strong that it gave character to the medicine of the eighteenth century. In the words of the Testament I might say, Sydenham begot Boerhaave, Boerhaave begot Van Swieten, Van Swieten begot John Peter Frank. Sydenham and his generation of followers are the flower of the whole century, and their spirit penetrates everywhere. In those times the senses alone were the diagnostic apparatus. The

material. Thus it may be that the floating poison may become even beneficial. Is it for that reason that patients who have outlived a serious attack of typhoid fever, are endowed with better nutrition and more vigor afterward than they ever enjoyed before?

exact methods of the following decades have sharpened the senses of the English and American medical men, and rendered their observations more accurate and their results more correct. Live and learn has been their pass-word. No new methods have ever been neglected, only unfounded theories ought not to find root in the regular medical profession. As the best features of all experience and wisdom of all ages and all nations have been utilized in the establishment of our political system, thus the American medical mind has received, appropriated, and critically digested the results of foreign scientific labor and added of its own. It is with sincere pleasure that I have again read that interesting collective volume containing a century of American medical history. In it those of you who have not read it will find many a good reason to be proud of the achievements of our country. It is so modest in its tone and contents that many more names might have appeared in the enumeration of men and labors, not to speak of those who have added materially to our wealth of intellectual productions since. Its perusal will be a revelation to many who are in the habit of looking for everything new and trustworthy, and—that is the technical term now-a-days—epoch-making, from abroad. If there is anything which teaches us both justifiable pride and desirable modesty, it is the history of our science in our whole country. For besides a great many of the former and present members of this Academy who have accomplished lasting results, there are a great many other Americans in other States and cities who stand on a level with the best of all nations.

From the reading of old journals, I learned but lately that four years before Semmelweiss proclaimed the contagious character of puerperal fever against the protest of the official standard-bearers of obstetrics in Austria and Germany, our own anatomist, our philosopher, our poet, our autocrat, our own Oliver Wendell Holmes, taught, it is true, against the ridiculing sneers of Hodge and Meigs, the frequent transmission of puerperal fever by physicians and nurses. I might go on a long time, but I do not stand here to extol America or American medicine. Still, I feel strongly that we may be well satisfied with what we, not protected by governmental interference, unaided by a slow growth through centuries, have accomplished in a proportionally short time. The last few decennia gave us the library of the Surgeon-General's office, the subject catalogue, the medical and surgical history of the war, standard books recognized as such in Europe, great journals, and a goodly array of valuable monographs, and vastly improved college education; they have raised great surgeons and clinicians of universal reputation, and a progressive profession whose aim and best efforts are directed toward the improvement of medical training, and the sanitary condition of the people.

All this I firmly believe is true. If it were not, let us make it so. If it be, let us still rise and work, and with all that, let every man among us feel what Holmes said forty years ago: "I am too much in earnest for either humility or vanity."

Dr. Jacobi then introduced Dr. Chadwick, of Boston, who, having presented to the Academy a copy of the latest photograph of Dr. Oliver Wendell Holmes, read an open letter from the latter to Dr. Barker on the occasion of his retirement from the Presidency of the Academy.

CORRESPONDENCE.

DRAINAGE OF CEREBRAL ABSCESS.

To the Editor of The Medical News.

Sir: In the issue of The News for January 10, 1885, is an editorial, viz., "Drainage of Cerebral Abscess," to which I desire to call your attention. From some cause, I failed to notice at the time the editorial in the number for Aug. 2, 1884, to which you refer. But in the issue for January 10, 1885, you repeat the portion of it which I wish to notice, when you say, "Up to that time, August 4, 1884, only three cases of cerebral drainage had been reported." Then in this number you add Dr. Noyes's remarkable case, which appeared in the July number of the *American Journal of the Medical Sciences*, and say: "Unless we greatly mistake, 2d, Dr. Noyes led the way on this side the Atlantic in draining a cerebral abscess. 3d. But the first operation of the kind must be credited to Buchard, whose case is published in the *Deutsche Zeitschrift für Chirurgie*, Bd. xv., 1881." You give the credit, if any, to Buchard, Fluhrer, and Lee, all foreigners, and fail to mention a single American in this connection, except to credit Dr. Noyes for the first operation on this side of the Atlantic, and, as I understand it, Dr. Kemper the second. I am unable to refer to any particular case just now but my own, which was reported in the *American Medical Weekly* for May 9, 1875, but I am impressed with the idea that, in my reading, I have seen more than one case reported by American surgeons. But, let this be as it may, my case alone makes it unjust to your countryman to say that, up to August 4, 1884, there were only four cases, including Dr. Noyes and the first foreigners.

It also proves you are mistaken in giving Dr. Noyes the leadership on this side the "big pond," unless his case occurred at a much earlier than its record in the *American Journal of the Medical Sciences* would indicate —July, 1882.

3d. You are also mistaken in giving Buchard the credit, if any attaches to it, of being the first to use drainage in cerebral abscess. My case occurred on the 9th day of March, 1875, and was read by Dr. C. W. Kelly, of Louisville, before the Kentucky State Medical Society, at its meeting, on the 9th of April, in Henderson, Ky.; but not, as stated in a note by the editor, *sent* to him, but *handed* to him at the meeting, as the writer was present. Its reading called forth considerable discussion at the time as to the local lesion of the brain. However, I send you a copy of the journal in which it was published. You will find it a very similar case to that reported by Dr. Noyes. You will perceive that I advocated drainage, and secured it by position and the use of tents. I did not specify the material of which they were made, but would state here that it was of strands of "saddlers' silk," the material I have continued to use up to the present time, when obtainable; when not, I have used horsehair, and even flax thread. I prefer silk to any other material, except in long fistulous tracks, with sac walls. When these are split open down to the lining membrane, I always use long horsehair, placing as many horsehairs in together as will fill up the original fistulous track, and then bring the edges of the wound in apposition by sutures and adhesive strips, leaving several inches of the hair pro-

jecting at each end of the wound to excite and keep up suppuration and drainage at the same time; and, as the fistula fills by granulations, I draw out the hairs one by one until it has quite healed. But excuse this digression.

I do not know who may have been the first to use drainage in cerebral wounds, consequently I make no pretensions to priority. I believe Dupuytren was the first one who was bold enough to open an abscess of the brain, but whether he employed drainage or not I am unable to say, but it appears to me that *instinctively any* surgeon who had to deal with intercranial suppuration or wounds of the cranium, involving brain tissue, *would think first* of securing the most *complete* drainage, and establish it either by tubes, capillarity, position, or, if necessary, by counter-opening with the trephine, as in Dr. Noyes's case. But it seems to the writer that he might have established sufficient drainage by position, and the repeated changes of silk, renewing, as it were, the capillary drainage, aided by position, without the additional danger of trephining the orbital cavity. Of course, I did not use drainage-tubes in my case, because there was none in use at that time, and I do not suppose that I had ever heard of one, but I never use them now except in very large wounds or large pus cavities; they are too irritating, and in small cavities or wounds I prefer the coarse saddlers' silk, and would use this in draining an abscess of the brain now as I did ten years ago in the case referred to, and which you will find, on reading, somewhat identical with Dr. Noyes's, and similar in its history Owing to recovery, which, in the discussion before the Society I attributed *solely* to drainage, the case is very remarkable, and as it has been a long time since it was reported, I hope you may see proper to republish an abstract of it, whether it be considered legitimately as a case of cerebral wound-drainage or not.

In the March number of the *Richmond and Louisville Journal*, 1874, a remarkable case of "compound comminuted fracture of the cranium is reported by the writer, in which the accident occurred on the 1st of September, 1873. Though extremely grave, yet the unique and novel manner in which the wound was inflicted added to its interest, which was with the point of the horn of an infuriated cow, in a boy of six years. The point of her horn entered the inner canthus of the left eye, penetrating the roof of the orbit, passing upwards beneath the left half (near median line) of the os frontis, making its exit about the suture of the left parietal and frontal bones, just in edge of scalp (patient having a high forehead), fracturing the frontal bone from the inner angle of the orbicular arch to the frontal border, or, in other words, from entrance to exit of horn, tearing skin off forehead and a portion of scalp, and fracturing the frontal bone to within a half inch of the external angle of the orbital arch, throwing the whole back as a door on its hinges, the skin of the temple forming the hinge. The horn ploughed, as it were, a furrow in the anterior lobe of the brain.

"The fracture made near the median line was irregular, leaving midway between the point of entrance and exit, a triangular point of bone, the base of the triangle attached to the right half of the frontal bone. The upper left eyelid was detached beneath the brow at its inner orbital angle and its nasal attachment, for two-thirds of its width outwards.

"The broken bones, four in number, were dissected carefully from the skin and periosteum, the loosed brains removed, and the skin and nearly all the periosteum replaced, apposition being secured by twenty interrupted sutures. A point at the internal angle of the orbital cavity was left open for drainage, which proved sufficient, as the discharge was not very great at any time."

No dressing but cold water. Patient recovered, and is at this writing an intelligent and very robust youth of about seventeen years of age, and has as solid and complete an osseous frontal bone as before the pieces were removed. Though I scarcely mentioned drainage in the report of this case, yet it was a predominating idea with me at that distant period, when I had heard nothing specially said about draining wounds of any description. Then I used a small bundle of flax threads twisted into the drainage opening left for this purpose where the horn entered the roof of the orbital cavity. But as drainage is not dwelt upon, or directly mentioned in this case, I claim nothing for it on this point, and only mention it as a remarkable recovery from extensive injury to the brain, and especially for the unique manner of its occurrence.

In a more recent case of compound fracture of the skull, July, 1880 (never published), in a negro child aged 4 years, produced by the kick of a horse, fracturing the left parietal and posterior border of frontal bone, the skull was crushed in, producing a star fracture, with the points of the star reversed, or terminating in the centre of the fracture.

I found the child comatose, with cold extremities, and pulse almost imperceptible. With a common gimlet, I carefully made a hole in the centre and most depressed point of the fracture, where the points of the star or triangles met, and by cautiously and slowly using it as a lever, I succeeded in raising one of the points sufficiently to enable me to introduce an elevator, and after much manipulation, breaking one of the triangle points in my efforts, I succeeded in raising the three depressed points nearly to a level with the sound bone. The following device was improvised for draining any blood or accumulated fluid, notwithstanding an unfavorable prognosis was given—the case was pronounced hopeless.

A large goose-quill was procured, and both ends cut off; this was threaded loosely with threads of "saddlers'" silk, about six inches in length. One inch of the silk projected from the end of the quill that was intended to enter the opening in the skull made by breaking off one of the angular points, and three inches of silk beyond the external end of the quill. This "rig" was placed in the wound, and the mother directed to keep the child on his left side. Hot applications were made to the extremities, and only cold water dressings used to the head.

In ten or twelve hours, reaction was established; pulse 130 and full, but no signs of returning consciousness up to the fourth day, when he seemed to recognize his mother by following her movements with his eyes. Pulse 105. On the fifth day there was very little, if any, fever, and the patient appeared rational, eating with seeming appetite the milk and bread with which his

mother fed him, spoonful at a time. At first there was only bloody serum discharged from the wound; but on the fourth day this was mixed with pus.

It was impossible to impress the mother with the importance of keeping the wound downward. On every visit, I found the child either on his back or right side. She said she "was afraid of hurting the sore."

On the seventh day I found him again in profound stupor, from which it was impossible to arouse him. The quill-tent had been removed by the mother, "because it was hard to keep in place, and she knew it hurt him." The first objection was true; it was hard to keep in place, but this I have since remedied. On gently probing the wound, I felt projecting into the hole in the skull a *tense* membrane; introducing the tip of my little finger, it felt like the dura mater with pus beneath it. I punctured this membrane with the point of a thumb-lancet, and pure, healthy pus welled out freely; after some hours he could be aroused for a few moments at a time.

On the next day he again appeared rational, and would eat when food was placed to his mouth. He complained of pain when moved; but at no time did he articulate a distinct word. This apparent improvement continued up to about 9 o'clock A. M. on the tenth day from the accident, when he was suddenly seized with a terrible convulsion, and died before it entirely subsided.

It is just possible that this case might have recovered if he had had an intelligent nurse, and but for the extreme ignorance of his mother—his only nurse—with complete and constant drainage of the wound, even after the opening of the abscess, may have saved the child's life.

Since I have frequently used this—sort of compound of tube and capillary drainage—I have corrected its disposition to slip out of the wound, by cutting from the end of a rubber tube, about one-eighth of an inch long, two pieces for each quill; they must be, of course, small enough in calibre to fit tightly on the quill. I force the quill first through the piece of tubing intended for the end that enters the wound, graduating the distance from the end of the quill in proportion to the depth of the wound; secondly, cut a hole a little smaller than the quill through a strip of rubber adhesive plaster, cut in proportion to the surrounding sound parts, then run the external end of the quill through this strip of plaster, placing it up to the rubber shoulder previously placed on the quill; then the other piece of tubing is placed on the quill against the plaster, but external to it; lastly, the ends of the plaster are attached to the skin on each side of the wound. If the wound is large, any number of these quills, filled with silk, or without, may be placed in the wound, in fact, one or more between the sutures if required or desired.

I have had no experience with bone drainage-tubes, but prefer the quills, when long enough, to the rubber. They soften somewhat after immersion in the secretions, but seldom enough to diminish their calibre. Should this happen, a new one is easily made to take its place. In my hands this little "rig" has seemed less irritating and more easily managed, and well adapted to small wounds and ordinary abscesses, and cannot slip in and out of the wound.

J. P. Thomas, M.D.

Elmo, Ky., January 25, 1885.

THE USE OF THE BROMIDE OF SODIUM IN SEA-SICKNESS AND IN THE NAUSEA OF PREGNANCY.

To the Editor of The Medical News.

Sir: In a late number (January 17, 1885, p. 78) of The Medical News, Dr. Reichert reports the result of his experience in the use of the bromides in a few cases of sea-sickness, saying, in conclusion, that in one bad case the bromide of sodium was effectual in large doses. My own experience in the use of this drug for sea-sickness differs somewhat from that of Dr. Reichert, in that I have found that small doses of the salt, administered for a week before embarkation, and continued throughout the voyage, have acted most satisfactorily in the few cases in which I have had occasion to use it.

The employment of bromide of sodium as preventive of sea-sickness was first suggested to me by Dr. Robert P. Harris, in 1883, in the case of three members of my family who were about to voyage to England; all were susceptible to sea-sickness, and one of them especially suffered from the motion even of the ordinary river ferry boats. About a week before they sailed, I began the administration of the salt in ten-grain doses, thrice daily, which was reduced to twenty grains daily after the steamer had left New York harbor. There was but little rough weather, and no one of them suffered any sensation at all approaching sea-sickness.

The prescription was renewed in Liverpool, and about a week before the sailing of the return steamer, one member of the party began taking the bromide as before; the others, relying upon their former immunity, neglected it, the result being that, although the ocean journey was not a whit more stormy than the former voyage had been, the one who was faithful to the salt was the only one who escaped sea-sickness. Since that time I have used the salt in exactly the same way on eleven persons who were about to take sea-voyages, and with perfectly satisfactory results in ten. In one the failure was due, I think, to the fact that the subject discontinued the use of the bromide because of the eruption of acne which it produced.

I do not believe that large doses of the salt are at all necessary as preventive of sea-sickness. I have frequently prevented motion-sickness in myself by taking one large dose (℥j) of the bromide of sodium; but I have also found that three smaller doses (say, gr. x), taken at intervals of four hours before I tried to induce the sickness, were quite as effectual as the larger amount, and I think that it is the gentle continuous action of the bromide which is effectual in preventing sea-sickness, not the tremendous sedative effect of large doses. One of my patients was a lady who, some years before, had travelled to Europe, when the duration of the voyage was nearly twice as long as it is now. She was at that time violently sea-sick, both going and coming, and almost every vaunted remedy was tried without avail. The bromide of sodium was quite sufficient in gr. x doses to give her immunity during her second voyage.

I do not doubt that the salt will prove a disappointment in many cases when it comes to be more generally used. That it was successful in all of the cases in which I had an opportunity to note its effect, I regard as simply a coincidence.

Dr. Albert H. Smith, of this city, was in the habit of

advising his classes at the Lying-in Charity to employ the bromides in the nausea and vomiting of pregnancy, his experience being that the salt invariably modified the severity of that most troublesome and annoying complication, and in many cases removed it altogether. He was accustomed to give the bromide of sodium in large doses (gr. xxx three times a day), and I have found that, in my hands at least, a smaller one has always failed of the desired effect. I have used the salt in twenty-one cases of pregnancy when nausea was present; in sixteen cases the symptom disappeared entirely while the drug was being used; in two cases it persisted, but in a less degree; and in three cases the salt had absolutely no effect whatsoever.

MONTREAL.

(*From our Special Correspondent.*)

SINGLE KIDNEY.—At the Montreal General Hospital, a single kidney was discovered in a patient who had died from the effects of an injury to the spine. The kidney was of ordinary size, and situated in the normal position of the right kidney. On the left side, no kidney could be found, its place being occupied by a mass of fat; there was only one ureter entering the bladder—that for the right kidney.

NEW SENATOR.—Dr. Sullivan, of Kingston, Ont., who was last year President of the Canada Medical Association, has been appointed by the Government to be sent to the Dominion Senate. Dr. Sullivan is an eloquent speaker, and has been a zealous politician for a number of years. His knowledge of sanitary and medico-legal matters will be of great value in the Upper House.

JEFFERSON MEDICAL COLLEGE.—It is stated that Prof. Mallet intends, at the close of the session of this year, to resign the Chair of Chemistry to which he was elected last autumn, and that he will resume his professorship at the University of Virginia. Prof. Mallet has proved a very acceptable teacher to the medical class at Jefferson, and his intended resignation is greatly regretted.

PROF. OSLER has been granted leave of absence by the Trustees of the University of Pennsylvania, and he sailed last Wednesday for England, where he will deliver, in the month of March, the Gulstonian Lectures before the Royal College of Physicians of London.

ACADEMY OF MEDICINE IN IRELAND.—At a special general meeting of the Academy of Medicine in Ireland, held January 17th, on motion of the General Council, Dr. Austin Flint, Sir James Paget, Prof. Billroth, Prof. Virchow, Prof. Pasteur, Prof. Charcot, Dr. Keith, Prof. Schrœder, Prof. Kölliker, and Sir Joseph Lister were elected honorary members.

ERRATUM.

In the report of the proceedings of the New York State Medical Society, on forty-fourth line of page 156 of our last issue, for "Dr. Mundé," *read* "Dr. W. Gill Wylie."

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 3 TO FEBRUARY 9, 1885.

TOWN, F. L., *Major and Surgeon.*—Granted leave of absence for twenty days.—*S. O. 14, Department of Texas*, Feb. 4, 1885.

WATERS, WM. E., *Major and Surgeon.*—Granted leave of absence for one month.—*S. O. 24, Department of the East*, Jan. 31, 1885.

WILSON, WM. J., *Captain and Assistant Surgeon.*—Ordered for duty as Post Surgeon, Fort Preble, Me.—*S. O. 27, Department of the East*, Feb. 5, 1885.

WOODRUFF, EZRA, *Captain and Assistant Surgeon.*—Ordered from Willet's Point, New York Harbor, to Department of Dakota.

TAYLOR, MARCUS E., *Captain and Assistant Surgeon.*—Ordered to Department of the Missouri.—*S. O. 30, A. G. O.*, Feb. 5, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FROM JANUARY 1 TO FEBRUARY 7, 1885.

STONER, G. W., *Surgeon.*—When relieved to proceed to Washington, D. C., for duty, as Chief of Purveying Division, Jan. 16, 1885.

BENSON, J. A., *Passed Assistant Surgeon.*—When relieved, to proceed to Chicago, Ill., for duty, Jan. 12, 1885.

CARMICHAEL, D. A., *Passed Assistant Surgeon.*—When relieved, to proceed to Cairo, Ill., for duty, Jan. 3, 1885.

AMES, R. P. M., *Passed Assistant Surgeon.*—When relieved, to proceed to New York, N. Y., for duty, Jan. 14, 1885.

URQUHART, F. M., *Passed Assistant Surgeon.*—To proceed to Norfolk, Va., and assume charge, Jan. 12, 1885.

BROOKS, S. D., *Assistant Surgeon.*—To proceed to Evansville, Ind., and assume charge, Jan. 14, 1885.

CARRINGTON, P. M., *Assistant Surgeon.*—To report to Surgeon-in-charge, St. Louis, Mo., for temporary duty, Jan. 17, 1885.

LONG, W. H., *Surgeon.*—Relieved at Detroit, Mich., to proceed to Chicago, Ill., and assume charge, Feb. 4, 1885.

GODFREY, JOHN, *Passed Assistant Surgeon.*—To proceed to Vicksburg, Miss., and Memphis, Tenn., as inspector, Feb. 6, 1885.

BENNETT, P. H., *Assistant Surgeon.*—To assume temporary charge of the Service at Detroit, Mich., Feb. 4, 1885.

WILLIAMS, L. L., *Assistant Surgeon.*—To report to the officer in charge at Detroit, Mich., for temporary duty, Feb. 7, 1885.

RESIGNATION.

MILLER, T. W., *Surgeon.*—Resignation accepted by the Secretary of the Treasury, to take effect March 1, 1885, Feb. 4, 1885.

PROMOTIONS.

STONER, G. W., *Surgeon.*—Promoted and appointed Surgeon by the Secretary of the Treasury, from January 16, 1885, Jan. 14, 1885.

GODFREY, JOHN, *Passed Assistant Surgeon.*—Promoted and appointed Surgeon by the Secretary of the Treasury, from March 1, 1885, Feb. 6, 1885.

APPOINTMENTS.

CARRINGTON, PAUL M., M.D., of Georgia, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, Jan. 16, 1885.

WILLIAMS, L. L., M.D., of South Carolina, having passed the examination required by the Regulations, was appointed an Assistant Surgeon by the Secretary of the Treasury, Feb. 6, 1885.

ORIGINAL LECTURES.

VERSIONS AND FLEXIONS OF THE UNIMPREGNATED UTERUS.

A Course of Lectures delivered before the Boerhaavian Society.

BY ELY VAN DE WARKER, M.D.,

OF SYRACUSE, N. Y.; FELLOW OF THE AMERICAN GYNECOLOGICAL SOCIETY.

LECTURE VII.

THE INTRAUTERINE STEM.

TWELVE or thirteen years ago, when I first took up the subject of the intrauterine stem in a practical way, I quickly found that there was no subject in the whole range of gynecology that would so lay its advocates open to distrust. The teachers and leaders of opinion in America, without an exception, condemned in no moderate terms both the practice and the men who were reckless enough to employ it. Had any of the patients whom I treated with the intrauterine stem met with a fatal accident while wearing the instrument, I do not know of but two or three prominent members of the profession who would have testified that the treatment was legitimate.

The majority of the enemies of this method were men who had never used the intrauterine stem, and had based their opinion upon the experience of others, or had had an unfavorable result in one or two cases. Against this opposition it was useless to bring either arguments or evidence. It was equally useless to contend that the successful use of this instrument implied a distinct gynecological operation, with well-defined rules for the selection of subjects, with indispensable methods of preparation, and, lastly, the use of an instrument that conformed to a few fixed laws of pelvic mechanism.

Opposition has never obliterated the idea; that has remained, and gradually brought over converts to the treatment. It will be interesting to trace briefly the history of this method. From it we shall learn two lessons: first, that a germ of truth in an idea is worth more to human progress than the factional opposition of legions; and, secondly, that the use of the intrauterine stem has been the means of giving stability to many theories of intrauterine treatment.

That this treatment should meet with opposition; that it should have its periods of abandonment and revival, is but the fate of every radical method. In one respect the history of this instrument is anomalous. Its popularity seems to be sectional; and in America it has been, in a measure, crowded out by a surgical operation not unattended with danger, and one that is in no sense a cure of flexions of the uterus.

The report of the Commission to the French Academy of Sciences is the one event in the history of the intrauterine stem to which it owes its ill-repute.

In the light of the quarter of a century which has passed, I believe that that expression of opinion has no longer any value, and that we have ample evidence for a reversal of the verdict.

In order to understand the value that belongs to the formally expressed judgment of the French Academy, it will be necessary to review briefly the grounds upon which that judgment was based. We may see in this two factors: first, the instruments then in use as intrauterine supports; and, secondly, the men who passed judgment upon them.

Such was the character of the debate before the French Academy, that I cannot resist the conclusion that there was a man as well as an instrument on trial; the first upon a question of veracity, the second upon its merits.

Under the circumstances, it is nearly impossible that the participants in the discussion should not have confounded the man with the instrument. It is well known that in 1851 Valleix, stimulated by the report of Simpson in the *Dublin Journal* of May, 1848, made trial of a modification of Simpson's instrument, and published his results in 1851. That two years later, in 1853, in a more elaborate paper, he gave the method of the introduction of his "rédresseur utérine," and the exact indications for its use, concluding with the statement that in 117 cases so treated, 78 were completely cured; in 14 the treatment was wholly favorable; and in the remaining cases there was but slight improvement.

The unpleasant results which Valleix experienced were slight metritis, for which he employed bloodletting and morphia, hemorrhage, which abated of itself, hysterical accidents and febrile symptoms, which were, he said, without significance. That such results were reached in five years in a field entirely new and full of interest, naturally drew upon the author the attention of all gynecologists, and raised in some minds doubts of his veracity.

The effects of Valleix's enthusiasm was soon apparent. In less than a year the first note of alarm was sounded. Strange to say, it was neither Valleix nor his instrument which led to the fatal accident; but it was the result of what we would now regard as either gross ignorance or carelessness on the part of a celebrated man. On the 4th of February, 1854, Broca published the case of a woman who was admitted to the hospital under his care with symptoms of peritonitis; it was found that anteversion existed. From the 7th to the 11th of October inclusive the sound was daily introduced, and the organ restored to its normal position.

On the last day pain followed, and death occurred eleven days later. To us, this experiment of Broca calls to mind but one fact, which we all know: that in peritonitis we are not to sound the uterus, much less introduce an intrauterine stem. In 1854 this experiment and its results had a much broader significance. It seemed to establish the fact that the new method of intrauterine mechanical support was one full of danger to life. The heroism of Broca in publishing his case encouraged others.

It was discovered that Aran, Nélaton, and Cruveilhier

had likewise lost cases; not from an imprudent use of the sound, but of the rédresseur. From these cases resulted the appointment of Depaul, Huguier, and Robert as a commission, on the part of the Academy, to examine critically the merits of the rédresseur, the chief result of which was the report of Depaul. The character of this report we all know. It excited in the body of the Academy considerable mistrust of the validity of Valleix's results.

Depaul reported twenty-seven cases of Valleix, Gaussail, and Piachaud, which had been treated with nominally good results, but were afterward ascertained to have been followed by many bad results. P. Dubois related that he sought out many of the women who were discharged by Simpson and Valleix as cured, and found them still suffering from the displacement. On the formal expression of opinion by the Academy, it is needless to comment in full. It condemned all forms of intrauterine mechanical treatment, although there was evidence to condemn but one—the rédresseur of Valleix.

It may have expressed the opinion of the Academy as a body, but it did not express that of the members individually.

The majority of the Commission itself dissented from the sweeping report of Depaul. Huguier and Robert asked that the rédresseur be not unconditionally rejected. Hervey de Chigoin, Velpeau, Latour, and others opposed the opinion of the Academy. But dissent was without avail. It was an expression of a majority, the force of which existed in numbers, not in truth.

Instead of there being evidence before the Academy sufficient to condemn both the theoretical and practical employment of all forms of intrauterine mechanical support, there was proof of the dangers attending the use of a single, very imperfect instrument.

Valleix modelled his rédresseur after Simpson's intrauterine stem of 1848; yet, nearly alike as they were, they exist in history as two very different instruments. That of Simpson had a very worthy career; so far as actual danger of life was concerned, the most complete condemnation that it ever received was the fact that its inventor himself finally abandoned it.

The instrument of Valleix was made famous by a series of fatal accidents. The inventor was evidently in doubt as to what was really necessary to the proper intrauterine support of the organ. He first made them of six, then of five, then of four centimetres in length, and finally just as short as possible. While he was thus shortening the stem, he was overlooking a serious mechanical defect. Upon the stem of Simpson there is a flange which supports the external os; Valleix supported the uterus by an inflatable ring pessary distinct from the stem, omitting the flange, and thus allowing the uterine fundus to rest upon the end of the instrument so as to be irritated or seriously injured. However short he made the intrauterine part, or changed the curve of the external support, it was in danger of penetrating too far. Thus, to the sound of Broca, and the unfortunate rédresseur of Valleix, we owe the unfavorable verdict of the French Academy.

At Vienna and Berlin, at nearly the same time, opposition was not less marked, or debate less heated; but approval and disapproval were individual expressions of opinion. There was no effort to create an *index expurgatorius*, after the manner of the French Academy, or to make a theatrical proclamation of proscription as an official act. Unscientific as this proceeding was, however, the effect was quite a general abandonment of this mode of treatment.

Fifteen years passed before the reaction set in, an interval marked here and there by a paper in the periodical press, from the pen of some one who was cautiously working at the problem. The debate in 1868 in the London Obstetrical Society signalized the period of revival. An animated discussion in the Association of Physicians and Naturalists, at Dresden, in the same year, indicated that this revived interest was widespread. This brings us to the second period in the history of the intrauterine stem, which was characterized, not so much by the invention of any decidedly new form of mechanical appliance, as by a total abandonment of the stem with external support.

It having been shown that the decision of the French Academy was based upon this abandoned form of instrument, and included all forms of intrauterine support; not by direct evidence, but by hasty theoretical inference, it follows that, if like unfavorable facts cannot be brought against properly constructed instruments of the second period—those with intravaginal support—the decision of the Academy must be reversed, and the proper use of intrauterine pessaries be given a legitimate place in gynecic surgery, unhampered by timidity or doubt.

The earliest record we have of death from a stem without extravaginal support is referred to by Amussat about 1828. So far as I am able to find out, the report of a fatal result from the use of the "petite tigi droite en ivoire," by Amussat, comes to us at third hands. Raciborski refers to a thesis by Dr. Quetier (1828), and states that Amussat found the dangers of this treatment confirmed. Tilt states that the case terminated fatally, and assigns the date to a year earlier than the thesis of Quetier, but gives no reference.

Now it is not a little singular that Raciborski does not refer to a fatal case under the care of Amussat, and that it should have escaped the careful research of Winckel, who was obliged to refer to the unsustained authority of Tilt in the matter of this case, adding the comment that this statement does not wholly agree with that of Quetier: "Dass dieses Verfahren mehrere Male geglückt sei."

The statement of Tilt that fourteen fatal cases are known to have occurred in France, America, England, and Scotland, is frequently referred to by the opponents of the intrauterine stem. I do not wish to impugn the veracity of Dr. Tilt, but it is not usual to make statements of such vast importance as this in so summary a manner in other departments of science. No American author of a treatise upon gynecology that I have ever seen makes any allusion to a fatal case in America. Hodge, who ought to know of a fatal case, as late as 1868, says: "In America we have seen no favorable report of any importance. The writer has heard of its employment in some cases, but with no permanent advantage."

At this period in the history of the intrauterine stem, the centre of activity was transferred to England. In 1864 Dr. Greenhalgh exhibited his intrauterine instrument. In 1865 Dr. Aveling exhibited an intrauterine

spring pessary, which he called a spring tent. The next year was remarkable for the number of new instruments offered to the profession. Dr. Aveling presented to the Obstetrical Society the intrauterine stem of Dr. Graham Wier, belonging to the diverticulating class. Dr. H. G. Wright published the description of his instrument belonging to the same class as the above. The instrument of Dr. Meadows was also presented at the same time. While Dr. Aveling concluded the progress of the year in the mechanism of gynecic surgery by bringing to the notice of the profession a flexible stem of coiled wire, which, as late as 1873, he suggested might be united with the flexible rubber stem of Dr. Squarey. In 1869 the instrument of Dr. Routh was brought forward; that of Dr. James Young, of Edinburgh, in 1870; that of Dr. W. S. Playfair in 1871; that of Dr. Wynn Williams in 1872; that of Dr. Thomas Chambers in 1873; those of Mr. Lawson Tait and Dr. Squarey in the same year. On Wednesday, December 3, 1873, occurred a remarkable event in the history of the intrauterine stem. On that day, Dr. G. C. P. Murray, Dr. A. Wynn Williams, and Dr. T. Chambers each presented to the London Obstetrical Society a new form of the instrument. Dr. W. Ross Jordan presented to the Society a new form of intrauterine stem in 1874; Dr. Eklund, of Stockholm, Dr. Amann, of Munich, Drs. Clement Godson, G. Granville Bantock, and James Young, of England, each offered an instrument to the profession in 1874.

In 1860 Dr. Edward Martin improved Simpson's second form of instrument. C. Braun used advantageously a hard-rubber stem of his own invention (1864). Olshausen devised a new form (1867). In the same year Hildebrandt introduced an intrauterine stem made of lead. Dr. H. Beigel, in 1873, and Dr. Dühring, in 1874, each described new forms of the instrument.

In the United States, Dr. Peasley claimed advantages for two instruments of his devising (1866). Such inventive activity is only equalled in the history of one other instrument in the literature of gynecology—the obstetric forceps; and no other instrument, not even excepting the last named, can show a more brilliant array of careful, conscientious inventors and observers.

While the principle of construction of these instruments had changed in this second period, so also had the character of the opposition to their employment. The occurrence of no fatal case from their use any longer gave opportunity for the most potent of all arguments against them.

The mind of the profession was thus prepared to examine more carefully into the merits and demerits of this plan of treatment, and to understand both the proper construction of the instruments and the limits of their use.

I have but one other item to add to the history of the intrauterine stem. It transfers the interest to American gynecology, and to my mind gives additional lustre to a famous name. I received the following letter from Dr. Sims, which I transcribe entire, except a brief paragraph which relates exclusively to a personal matter of his own:

12 PLACE VENDOME, PARIS, Feb. 12, 1879.

MY DEAR DOCTOR: I am just now writing my chapter on displacements of the uterus, and in looking over authority at my command, I do not find your early papers on flexions. I have only your "Present Status of the Intrauterine Stem," etc., in the second volume of the *American Gynecological Transactions*. May I beg you to send me what you see I need, to do you and the subject full justice? I will return the documents if you have no duplicates. From awkward and badly conducted experiments in the early days of my experience, I was unfortunate with the stem, and I gave it up entirely; but I have now come round to your way of thinking, and I see and understand why I failed in my early experiments. Thanking you in advance, my dear Dr. Van de Warker, believe me, yours, very truly,

J. MARION SIMS.

The pleasure this letter gave me is now tempered with a sad regret, which you will all share with me, that Dr. Sims did not live to complete the work upon which he was engaged, and which, had it been completed, would have placed the intrauterine treatment of flexions upon a secure and scientific basis.

If one contemplates the treatment of a case of uterine flexion by the stem, one question must first be answered: Is it a suitable case? There are many pelvic conditions that forbid the use of the instrument. One condition is very common, and is more frequently associated with flexions than with other uterine displacements. This is pelvic inflammation—pelvic peritonitis and cellulitis. For our purpose it is not necessary to make any distinction between them; they are one disease. Speaking generally, they contra-indicate nearly all uterine manipulative treatment; but, so far as the endometrium is concerned with this surrounding condition, it is forbidden ground. The same rule applies to the stem as well as intrauterine medication, or the introduction of the sound. The acute stage no one is liable to mistake; but in the chronic state, in which we have to contend with its products in the form of pelvic indurations and adhesions, the contra-indications are not always so clear. It needs at times a very careful touch to establish the fact of uterine adhesion, especially when elongated, as Winckel shows beautifully in the illustrations to his *Pathologie der Weiblichen Sexuel-Organe*.

When we have to do with the non-suppurative products of inflammation, we must remember that we are dealing with a state not many removes from that condition itself. Therefore, so long as adhesions persist, we are in constant danger of a relapse, and nothing will do this so surely as uterine manipulation, especially that directed to the cavity of the organ. If I were to draw the line between the amateur and expert gynecologist, I should say that the former finds his methods attended with frequent complications, either primary or secondary, of pelvic inflammation, while the latter never has them. If, then, you find that the introduction of an intrauterine stem is followed by cellulitis, accuse yourself, or the form of the instrument, not the principle. You have mistaken your case, or failed in your manipulative tact.

Another class of women whom it is very difficult to treat with the intrauterine stem is the anæmic neurotic; and yet no class demands thorough treatment more urgently. Their pelvic organs are the seat of such active subjective symptoms, and the mental impressions will shift so quickly, that it will be difficult, if not impossible, to convince the woman that the presence of the instrument is not the cause of the pelvic distress.

If a patient of this character should have a friendly interview with a physician, and if, with the delicacy and kind regard for the reputation of a medical *confrère*, which is a leading trait of the profession, he were to inform her that the wearing of an intrauterine stem frequently proves fatal, you would find her at once to suffer such agony of mind and fear of death that you would have no alternative except removal of the instrument. Days, and it might be weeks after, would be spent in reëducating her, so that the instrument could be borne with mental comfort. I mention this because I have had the experience, and to make clear to you that we have a mind as well as a flexed uterus to deal with.

In these anæmic cases we meet with instances of great hyperæsthesia of the pelvic organs. If present in intense form, it would amount to a contra-indication. Usually this condition may be treated in connection with the preparatory measures to be shortly described. Pelvic tumors of any form would forbid the employment of the stem. Lacerations of the cervix would require to be repaired before the use of the pessary; and lacerations of the perineum, if extensive, might interfere with the action of the vaginal retaining part to such an extent as to make it very difficult to keep the stem in place.

Some cases of flexions are attended with frequent, prolonged, and profuse menstruation, which ought to be treated before the use of the stem. Such a state may be the direct outcome of the flexion, due to a strangulation of the uterine wall, and for which the stem would be efficient treatment. Speaking generally, however, my first statement would be the safer one to follow.

Now, having a proper case to treat with the intrauterine stem, I always begin with preparatory treatment. This consists in the use of the uterine probe, or sound. I call it training the uterus, and by it I expect to establish a tolerance of a foreign body in the cavity. I first wisely adapt the curve of the sound to the uterine cavity, and then gently introduce it, making no effort to straighten or replace the uterus. The introduction, even when very gently accomplished, is sometimes attended with pain. I leave the sound in place for from five to ten minutes, and the pain usually subsides; if not, I remove it, and the next day, or the day after, I repeat the operation, and do so until I find that the pressure of the sound no longer excites any pain. When this result is reached, I regard my patient ready for the use of the stem. This training of the uterine cavity is a measure closely related to like manipulations in other departments of surgery. The laryngologist so trains the fauces to bear the pressure of the mirror, and the genito-urinary surgeon will in like manner relieve the hypersensitive urethra. I have good authority for carrying the analogy still further. Paul Dubois contends that the stem pessary relieves by modifying the abnormal sensitiveness of the uterine cavity, just as a sound cures neuralgia of the neck of the bladder; while Malgaigne cites the case of a woman who was suddenly relieved of pain by the stem, the flexion being uncured. To those who have had considerable experience of the intrauterine stem, these cases are not unusual.

In some cases, by no means rare, it is not necessary to train the cavity, as the organ exhibits no intolerance of the instrument. The state of primary tolerance is usually found in long-standing cases of acquired flexions. The developmental flexion in young and nervous women requires the most careful preparatory treatment. This employment of the sound or probe serves another very useful purpose, It is very sure to correct any error you may have made in regard to pelvic conditions unfavorable to the use of the stem. Other complicating conditions attending the flexion may be treated on the principles already laid down. Since the publication of Dr. Mundé's paper on lymphadenitis, in the *American Journal of Obstetrics*, I have been able to recognize several cases of acute adenitis in the parametrium in connection with flexions of the organ. I am strongly of the opinion that this complication ought to be treated before the introduction of the stem. It would occupy too much space to enter upon the details of diagnosis and treatment of this complication here, for which object I take pleasure in referring you to Dr. Mundé's very able paper.

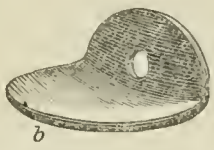
Conceiving our case to be a proper one for the employment of the stem, and the patient also in proper condition, it is now necessary to say something about the instrument itself. Of course, I have had my own model with which I have worked successfully for years, but in all I have written upon this subject, I have not said so much upon my own or any particular form of the stem as I have upon the correct principles of construction of the instrument. If a physician who is fairly familiar with pelvic manipulations has a correct idea of the theory of the stem, he may be trusted to employ it with safety and advantage.

An intrauterine stem must be made with reference to a few principles which I believe to be unalterable. First, the stem must be shorter than the cavity of the uterus, and so small in diameter that neither the outer nor inner os is stretched or occluded. Secondly, it must be supported wholly from within the vagina. Thirdly, the retaining part must be of such a size that it will not interfere with the action of the bladder or rectum, or with the comfort of the patient, and lastly, the retaining part must be of such a form and so adjusted to the vagina that it will not restrict the normal uterine mobility. In order to comply with the latter condition, we cannot limit ourselves to any one form of the retaining part. It is sometimes a difficult problem to solve so to adjust the retaining part to the vagina, that the stem is held securely in place while the uterus is not fixed immovably within the pelvis. The expulsive power of the uterus is, in some cases, considerable, and this power is usually exerted during menstration, when you are most anxious to keep the instrument in place. I have never yet failed to accomplish this, but in doing so I have invented quite a variety of vaginal attachments. In some cases it is better to readjust the instrument when it becomes displaced than to make the retaining part too secure, as in the latter the freedom of movement of the uterus may be too much restrained.

Anteflexion, like all forward displacements of the uterus, is the most difficult to replace and retain comfortably in position. The vaginal part differs materially from that of the retroflexion form. The idea was borrowed from Amann, but in his form of the instrument the vaginal attachment was rigidly attached to the stem, and the instrument was made to act in both forms of flexions by wedging cotton behind the vaginal flange in anteflexion, and before it in retroflexion. In

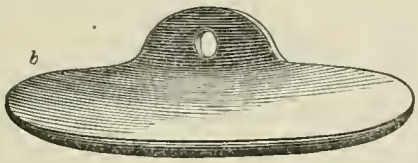
my modification the flange impinges against the posterior vaginal wall, and serves to correct excessive version. Fig. 1 shows the ordinary form of the anteflexion flange.

Fig. 1.



In Fig. 2 we have the same form modified so as to meet the difficulties offered by a short and very capacious vagina.

Fig. 2.



The scant dimensions of the vagina of the virgin required a further change in form, which is shown in Fig. 3. These cuts are taken from flanges that have

Fig. 3.

been used, and were invented specially for each case. I have said that this idea was borrowed from Amann; I ought to have said, however, that I had devised the anteflexion flange before I had seen his book, *Zur Mechanischen Behandlung d. Versionem u. Flexionen d. Uterus*, and that his published account antedates my own.

The retroflexion flange is a simple button-like attachment (Fig. 5). It is passed over the end, *a*, of the stem (Fig. 4) by means of a wire passed into the end of the stem. This attachment is also made of various

Fig. 4.

Fig. 5.

sizes to meet special difficulties. Tiemann & Co. make them for me, different in some respects from the one figured, which is solid except the central opening at *a*; the later form has large fenestra cut out of the solid portion, which gives the flange superior retaining power over the solid form, and affords ready exit to the secretions of the cervix. This form generally converts a retroflexion into a retroversion, but after years of work with this instrument, I have come to the conclusion that this is better than further to complicate the instrument by attachments to correct the resulting version. This can be better done after three or four months, when it is no longer necessary to wear the stem, by an ordinary pessary with the proper curve. In these cases we must not attempt too much, but be satisfied with making progress slowly. Patience and gentleness of manipulation must be cultivated as an art by the physician who aspires to treat uterine flexions successfully. I have on very few occasions used a flange larger than the one shown in Fig. 5. It will happen now and then that the flange and stem will get displaced. The remedy is a very simple one—replace them, remembering that if a stem is so securely held in place by the vaginal attachment that it cannot become displaced, it is probably too good a "fit," and the patient cannot wear it.

The introduction is a simple matter. The cervix is exposed by the Sims's speculum, and held gently but firmly by a volsella forceps. The stem is placed upon a wire and is passed into the uterine cavity in the same manner as a sound. The flange is slid over the wire as a guide and carried up to the stem, and by a little manipulation passed upon the stem until it fits firmly against the shoulder of the stem, at *a*, Fig. 4. At times, difficulty is met in passing the flexed point of the uterine canal. In this case a sound with a proper curve is first introduced, and the uterus straightened and held in that position for a minute or two, and then as the sound is withdrawn pass in the stem, before the uterus can recoil into its flexed form. If the stem should not freely enter the uterus, use the sound a second time, and again try and pass the obstruction with the stem. Remember that at no time is force to be used; if you were to lose your patience and the woman become tired, stop and try again some other day, rather than attempt to force the stem through the obstruction. I have never yet been obliged to resort to an anæsthetic in the manipulation I have just described; on the contrary I prefer to leave the patient alert to every sensation, and guide myself accordingly. If there is any pain after the introduction of the instrument, keep the patient warm in bed until it abates. At one time, I introduced the stem at my office, which I rarely do now; in fact, I do not believe that any form of intrauterine treatment is proper office work. I make a rule to do this at the patient's home, or in my private sanitarium.

Vaginal irrigation should be carefully carried out during the time the patient is wearing the stem. Constipation should be prevented, as difficult defecation is a frequent cause of displacement of the instrument. When the stem is nicely adjusted and is well borne, I allow it to be retained for two or three months. I then remove it and observe the case through a menstrual period in order to form an idea of the extent to which the patient has been benefited. If necessary, the stem is replaced, or a version pessary is substituted for it.

You cannot impress too strongly upon the mind of the patient, the need of regular visits at the office while the stem is in position; and, also, that it must be removed at a certain time. Notwithstanding all this caution, they will occasionally keep away, and wear the

instrument for many months. One of my cases retained the stem for over a year; purposely, however, as it gave her great relief from a severe dysmenorrhœa. Another precaution that I have observed in recent years, I feel it a duty to impart to you: I never employ the stem in strange patients, but wait until such a degree of mutual respect and confidence is established that I feel sure that the patient will remain under my care, or the care of a friendly physician, during the whole period of stem treatment; otherwise she may leave you while wearing it, and pass into the hands of a hostile doctor, or, what is just as bad, a friendly one who has a great fear of the intrauterine stem, and who will take from his library shelves the text-books written by several of my friends, and demonstrate to the patient the great danger of the instrument and her own narrow escape.

It is no part of my plan in this lecture to bring forward arguments to prove that the intrauterine stem is harmless and a legitimate method of treating flexions. I hope that at some future time I may be able to analyze and tabulate all my cases of uterine flexions so treated, which give good ground for my own faith in the instrument within the limits and precautions I have always observed, and which I have always taught. I may briefly state what my experience in its use has been. It has often surprised me with what comfort the properly adjusted stem can be worn. Menstruation is often undisturbed, quite often, however, it is somewhat more free and lasts a little longer; and then, on the contrary, I have introduced it in cases attended with menorrhagia, and found the discharge to become normal in time and quantity. It is my rule, in common with all physicians I believe who use the stem, to instruct the patient not to indulge in sexual relations while wearing it, yet it illustrates with peculiar force how little functional disturbance the stem may excite when I mention that Olshausen, in an artitle on "Conception unter Ungewöhnlichen Verhältnissen," in the *Archiv f. Gynäkologie*, vol. ii. p. 280, mentions two cases in which pregnancy occurred while the stem was present. In one case, the stem and ovum occupied the uterine cavity together twenty-seven days, and in the second case twenty days. Dr. Goodell, in the debate on my paper on the instrument, read before the American Gynecological Society at Boston, in 1877, mentions a third case of pregnancy under the same conditions.

One other precaution I have always observed, and with which I shall conclude this long and, I fear, tedious course of lectures. Whenever I find that the stem creates pelvic pain which does not subside of itself, I promptly remove it, just as I would any other pessary under like circumstances.

ORIGINAL ARTICLES.

REPORT OF A CASE OF PELVIC ABSCESS, COMPLICATED WITH A SEPARATION OF THE SYMPHYSIS PUBIS.[1]

BY S. D. THRUSTON, M.D.,
OF DALLAS, TEXAS.

MRS. D., a healthy, plethoric, American woman, 40 years of age, and weighing 150 pounds, began labor about 6 P.M., December 5. 1882. Saw her at 7 P.M.; found nature doing her work well, and safely. The progress was exceedingly good. and at 11 P.M. delivered her of a healthy boy. In the next thirty minutes the placenta was delivered, followed by a sharp hemorrhage, which was easily controlled. Remained two hours, ordered 10 grs. quin. sulph. at 6 o'clock in the morning, and gave instructions to keep her perfectly quiet.

Dec. 6.—Patient bright and happy; uterus well contracted; lochia free and pure; no tenderness; passed urine freely. Ordered 10 grs. quin. sulph. at noon, and night, and next morning.

7th.—Bright and cheerful, but complained of soreness in lower part of abdomen. Tactile examination revealed no peritoneal or metritic tenderness. Lochia free, and void of odor. Temperature and pulse normal. Ordered quin. sulph. grs. 10 at noon, and night, and next morning.

8th.—Thoroughly cinchonized; bright, but still complained of soreness in lower part of abdomen. Temp. 99½°; pulse 86. Examined, as was thought, thoroughly, and still detected no signs of impending trouble. Was in the act of leaving, when she said: "Doctor, you have not touched the sore place yet." Returned to the bed, and asked her to place the hand on the offending spot, when, strange oversight, the symphysis was the "sore spot," and examination disclosed the fact of a separation of the bones, the inter-articular cartilage being softened. The two bones moved upon each other with a peculiar cluck when either half of the pelvis was elevated, and caused great pain. Made a bandage similar to the body of a pair of drawers, with eyelets and lacings reaching from the lower margin of the pubis to the umbilicus, and a perineal band to prevent riding. This, when firmly laced, brought the two bones in close approximation; and by partially controlling the hip-joints, fixed the pelvis to a great degree, thereby preventing the edges of the bones from slipping upon each other, and giving much relief. Ordered quin. sulph., as for the preceding day, with the addition of morph. sulph. gr. ¼ every six hours.

9th.—9 A.M., nervous, fretful, and suffering much pain, notwithstanding morph. sulph. gr. j in the past twenty-four hours. Temp. 101°; pulse 100. No milk. Lochia void of smell, and normal. The external tissues over the pubis, and extending toward the left, were much tumefied, and very tender; mucous membrane of vagina hot. Directly under the arch there were thickening and perceptible induration extending along the roof of pelvis to the left; micturition free, and painless. Bowels moved in the early morning unaided; action healthy and non-offensive. Ordered hot linseed meal poultice to cover the entire inflamed surface, and to reach up as high as the umbilicus, the bandage to be laced over it. Hot water douche per vaginam, for fifteen minutes at a sitting, to be repeated every four hours. Quin. sulph. as on the preceding day, and morph. sulph. gr. ¼ every four hours.

P.M., quiet, but very tender to the touch. Lochia normal. No tenderness of body of uterus. Temp. 101½°; pulse 108. Ordered same treatment continued through the night.

[1] Read before the Dallas County Medical Society, 1884.

10th.—General condition not materially changed; more external swelling reaching in the direction of left inguinal region; more induration in roof of pelvis; tissues in floor, and in direction of left broad ligament, healthy; no lateral tumefaction internally to correspond to the lateral external swelling. Temp. 100°; pulse 108. No milk. Micturition painful, and difficult. Treatment same as previous day.

11th.—General condition about same; no diminution of the inflammatory process; indeed, rather increasing. Temp. 100°; pulse 108. No milk. Unable to micturate. From this day the catheter was necessary twice daily. The bowels were very regular, moving about once in thirty-six hours without aid of any kind, and in spite of the large amount of morphia used. The same treatment was continued, except an increase in the daily quantity of morph. sulph. to 2 grains, and diminution in quin. sulph. to 20 grains. The cellulitis gradually developed into a circumscribed phlegmon, which, on the 20th of December, could be easily detected occupying the left half of the pelvis anteriorly, and involving the tissues in front of and between the neck of the bladder and os uteri, as well as the cellular tissue lining the roof.

The hot douches were discontinued, as the pipe seemed to produce more pain than the hot water gave relief. From this time to the 29th of December, the condition of the patient was grave. Daily temp. 100°; pulse 120. Poultices to the tumefied surface. Quin. sulph. 20 grs., and 2½ grs. morphia, every twenty-four hours, constituted the medication, together with the free use of brandy. Phlegmon increasing in size, and patient beginning to show signs of hectic. Thus matters were up to the 29th. Bandage was removed on the 23d.

29th.—Wishing for assistance, I was requested to ask my friend Dr. John Pace to see her. Found the left anterior half of the pelvic cavity, extending from the symphysis up the left groin, well filled with the tumefaction, which was not so tender to touch. No evidence of pus, now so anxiously sought. Temp. 100°; pulse 120. Same treatment in every respect continued.

Jan. 16, 1883.—Since the consultation with Dr. Pace, the case has run on in the same groove. Patient holding her own. No increase in size of swelling, which is evidently preparing to break down. Temp. 100°; pulse 120. Brandy has relieved the signs of hectic. To-day could detect slight and deep fluctuations near the os vaginæ, a little posterior to the left labia, and directly under the pubic arch.

17th.—With Dr. Pace, made another thorough examination, and found evidences of pus; but so deep, concluded to wait the more thorough breaking down of the mass, notwithstanding the critical condition of the patient

19th.—With the assistance of Dr. Pace, the patient having been put under the influence of ether, a free incision with the bistoury was made, at the line of junction of mucous membrane and the skin of the left labia, when the fluctuation indicated the pus to be nearest the surface. With a forcible jet, a large quantity of very offensive sanguineo-purulent matter discharged itself. So large was the amount, and the shock threatening life, it was deemed prudent to check the flow. The incision was closed with a tent and compress of carbolized cotton, and the patient allowed to rally, which, under the influence of brandy, took place promptly. She pronounced herself more comfortable than for a month, yet the size of the tumor externally was not reduced.

20th.—Removed dressing, no discharge following; cavity was washed out with a solution of iodino-carbolized water until it returned free from stain. Used simple dressing of compress of carbolized lint—no tent—with emollient poultices externally. Temp. 100°; pulse 100.

21st.—Same condition of affairs, except rather more cheerful and much improvement in general facial expression. Temp. 100°; pulse 106. Continued treatment as on previous day.

22d.—M., severe rigor for more than an hour; great vital prostration; expression anxious; respiration shallow and sighing. Pulse 160. Rallied thoroughly by 2 P.M., under the influence of local heat, with hypodermatic of brandy and morphia.

6 P.M., fever very high. Temp. 106°; pulse 140. No pain and very slight tenderness over the tumefied surface. Treatment general.

10 P.M., fever declining. Temp. 105°; pulse 130.

23d.—1 A.M., fever still declining. Temp. 103°; pulse 120. Bathed in profuse sweat; rubbed surface dry with a coarse towel and then well with pulverized dry mustard; gave $\frac{1}{60}$ of a grain of atropia hypodermatically.

3 A.M., much improvement; surface soft, moist, and pleasant; sleeping quietly. Temp. 101°; pulse 120.

9 A.M., removed compress, explored the abscess cavity with a No. 9 rubber catheter, which was followed by the free discharge of a full quart of laudable pus. No shock or prostration. Washed out cavity as before, and inserting a thin carbolized tent of lint for drainage, dressed over all with antiseptic cotton. Temp. 99.5°; pulse 105.

6 P.M., has done remarkably well all day. Temperature and pulse same as morning.

24th.—9 A.M., slept soundly all night and is much refreshed. Feels hungry; remarkably bright and cheerful. Removed dressing. Three or four ounces of healthy pus discharged; dressing in all respects the same. Temp. 99°; pulse 96.

6 P.M., quiet and comfortable all day, and for the first time in forty-six days the temperature and pulse are normal. Continued treatment.

25th.—9 A.M., convalescence absolutely commenced. Temperature and pulse normal; slight discharge, no external tumefaction, and no tenderness or induration per vaginam. The walls of the cavity in close proximity; difficult to use the wash in consequence; spirits buoyant. Reduced the medication to five grains of quinia sulph. with morphia sulph. one-half grain morning and evening.

26th.—Still improving. Abscess cavity very shallow and discharge slight. Steadily improved from this date on to final discharge. The medication was restricted now to quinia and iron. No morphia being required to procure sleep or quiet pain, I

thought best to cut it off at once, as the disposition to the habit was very pronounced.

Feb. 7.—9 A.M., made a thorough examination per vaginam and rectum, both tactile, and with the speculum. No malposition or tumefaction to be detected in or around the uterus or its connective tissues; symphysis firmly united, abscess walls united and healed up to, and including the external wound; eschar small and smooth; health established. Recovery perfect. Nothing has been said about the adjuvants to the medical treatment. The medication during the entire time was confined to morphia, quinia, and brandy pro re nata. Atropia was used once. No purgatives were indicated, as the bowels were absolutely regular and dejections healthy. Hot water, made antiseptic with iodine and carbolic acid, was used per vaginam, and poultices externally. The main adjuvant, diet, consisted of eggs, milk, mutton, and beef soup, well boiled game and fish, with every alternate morning a plate of oatmeal mush, well cooked. The nursing was of the best, and aided materially in bringing the case to a happy conclusion. There was at no time—nor has been since recovery—any mammary secretion, nor even the least attempt at such natural function. The symphysis was so firm at the end of the fifth week as to allow the removal of the bandage.

In passing, it will be interesting to know that in her first labor—this being her second—she gave a clear and positive history of separation of the symphysis—not followed by cellulitis,—on account of which she was unable to walk for six weeks after delivery.

In reviewing the literature of this subject, but one author—Trousseau—alludes to this accident as a cause from which pelvic cellulitis may spring, and he is vague and indefinite in his language.

There are two points of interest in the subject which gave rise to this report, viz.: The cause and character of the cellulitis and the point of evacuation. Of all the causes laid down, parturition is the most frequent, and the character of the same is so general, that English surgeons give it the name "pelvic cellulitis." The French consider all such inflammatory processes as complications simply of "periuterine cellulitis." Thomas and Emmet lean very decidedly to the French nomenclature, while all speak of it as diffused, almost denying any phlegmonous nature. Of all other causes, nothing is said about a separation of the symphysis. That the inflammatory process in this case began from this cause is proved by the tissues involved. That it followed the course of a phlegmonous inflammation is made positive by tactile examination and its close confinement to the tissues in which it began. Beginning in the areolar tissue in front of and between the neck of the bladder and uterus, it involved in its development those tissues only which lie adjacent to and line the left half of the roof of the pelvis; although extending well up into the left inguinal region, the tissues there were only affected by the pressure of the growing phlegmon, and did not become part and parcel of the same. That it did begin in the cellular tissue covering the symphysis is arrived at from the fact that it was the first point of tenderness, and for three or four days the pain and soreness were confined exclusively to those parts. Advancing laterally, it confined itself literally to the left anterior segment of the pelvis, never invading the cellular tissue of the broad ligament or dipping down so as to reach that around the rectum. This was proved daily by rectal examination, while at the same time there was perfect regularity in the function of that organ, unattended with difficulty or pain. During the entire time the catheter was required twice daily to empty the bladder. In the left groin externally it gave to the touch the sensation of a well-defined and circumscribed tumor, and not that of a general induration and tumefaction of the whole superficial and underlying tissues. *Per vaginam*, the anterior wall, from the neck of the bladder and uterus to the left as far as the finger could reach, was tumefied and corrugated, and until the dimensions increased so largely the finger could pass upwards beyond the margin of the tumor, and downwards behind it, easily learning that the floor of the posterior left half of the vaginal wall was free from any complication whatsoever. The os uteri was tender, but passing the finger behind the posterior lip, either per vaginam or rectum, there was no swelling or pain in that organ. With the finger in the above position, the fundus could be handled with impunity by the other hand on the abdomen.

With these lights, therefore, it was very natural to arrive at the conclusion that the cellulitis was of the phlegmonous variety, notwithstanding the teaching of the learned authors, and that it had its origin in the tissues lining a divided symphysis. According to Thomas, so generally does "periuterine cellulitis"—it is by this name he describes all cellular disturbance of the pelvic cavity—involve all the adipose and areolar tissue of the pelvic cavity on the side where it begins, and so rarely is it purely phlegmonous that it remained for M. Simon, about 1853, to publish the only case, proved by autopsic evidence to be phlegmonous, and from comments of the celebrated gynecologist it is to be inferred that this case was to him of very doubtful nature. That the case here in point was no more nor less than a large phlegmon is based upon the evidence of *touch*, gathered from daily examinations, together with the closest watching and arduous search among the literature for any facts which might throw light upon the subject. The case was not only extremely serious to the patient, but interesting to the medical attendant, and for these reasons as many as six visits in the twenty-four hours were frequently made to perfect the diagnosis, and watch the safe progress of the case.

This brings us to the second point of interest, viz., the point of evacuation. All authors agree that one of many, and sometimes two, points simultaneously may be selected by a pelvic abscess to evacuate itself, but not one of them has ever hinted at the labia as a probable or remote point of exit. It is well known that pus in finding an outlet, by preference follows that course which offers the least resistance. That the labia therefore offered the least resistance is proved by the fact that the pus was there found, having followed its own law uninterfered with and unaided.

Now, to draw a rational conclusion, why the labia was the most available point, and offered the least resistance, involves several points upon which the diagnosis of phlegmonous cellulitis was based. Had the inflammation been general, or involved the entire adipose and cellular tissues of that side, one of the several general outlets would most probably have been sought; it would have found its exit in one of three ways—through the vaginal wall near the posterior lip of the uterus; or perforated the wall of the rectum, and passed off by that channel; or passing through the obturator foramen or sacro-ischiatic notch, pointed along the line of the psoas muscle, making a psoas abscess; or sought one of the four other less probable points of discharge, for the simple reason that either of those directions would have offered least resistance from that position than the direction of the labia. That neither of these probable outlets was sought, is due to the fact of the peculiar character and location of the tumor. It was an irregularly round phlegmon, confined to the tissues lying immediately under the roof of the pelvis adjacent to and closely connected with the neck of the bladder and os uteri, on the front and left side; from this position, the direct line of pressure and least resistance was in the line of the arch of the pubis to the left, and immediately behind the left angle of the os vaginæ. The strong tissue of the left broad ligament being healthy, resisted pressure in that direction; the hard walls of the pubis resisted pressure from that side, so that the resultant was necessarily followed, and this being between the two forces, in a direction downwards and outwards, the labia became the point of rest of the several forces. Had it been otherwise, the diffused cellulitis, forming several small nuclei of abscesses, each having its own centre of pressure, would have gradually broken down and coalesced into one. The line of resistance would not have been as above described, and it would ultimately have discharged itself at one of the points most commonly sought.

For the reasons herein set forth, the opinion is held that the foregoing was a case of phlegmonous inflammation of the cellular tissue of the left anterior segment of the pelvis, and not one of "peri-uterine cellulitis," or "pelvic cellulitis," as defined by the authors.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

III.

MERCURIC CHLORIDE.

BY GEORGE M. STERNBERG, M.D.,
SURGEON U. S. ARMY.

THE use of corrosive sublimate as a parasiticide and as an antiseptic agent for the preservation of animal tissues, etc., has long been known; but the researches which have established its value as a disinfectant are of comparatively recent date. These researches, made during the past four or five years, have demonstrated that the bichloride of mercury occupies a leading place among known germicide agents. Miquel places mercuric iodide above the chloride as an antiseptic, and it may be that it has a correspondingly greater germicide value. But from a practical point of view the chloride must still be accorded the first place on account of its cheapness and solubility.

My own observations are in accord with those of Koch, of Jalan de la Croix, and others, as to the power of this agent in dilute solutions (1 : 1000 to 1 : 10,000) to destroy the spores of bacilli—*B. Anthracis* and *B. subtilis*—and this constitutes the most difficult biological test known. Micrococci and bacilli in active growth, without spores, are killed by much weaker solutions (1 : 20,000 to 1 : 40,000).

Klein, of London, is, so far as I know, the only author who has reported results in conflict with these. In his recent work on *Microörganisms and Disease*,[1] he says:

"By sowing any microörganism in a nourishing medium, to which has been added a certain substance (*e. g.*, carbolic acid to the amount of 1 per cent.), and exposing this medium to the conditions of temperature, moisture, etc., otherwise favorable to the growth of the organism, if we find after the lapse of a due period the growth is retarded or altogether inhibited, the conclusion is drawn that this substance (viz., the carbolic acid of 1 per cent.) is an antiseptic. There is nothing more fallacious than this mode of reasoning; a great many microorganisms can be exposed to a 1 per cent. solution of carbolic acid for hours without in the least being affected, for on being transferred to a suitable nourishing medium they grow and thrive well. Similarly, by placing the spores of Bacillus anthracis in a proteid medium containing perchloride of mercury of the strength of 1 in 300,000, it is found (as Koch has shown) that the spores are absolutely incapable of germinating. But if from this the conclusion is drawn that perchloride of mercury of the strength of 1 in 300,000 is a germicide, I should most strongly dissent, for perchloride of mercury even of the strength of 1 per cent. is not a germicide any more than vinegar; for on placing the spores of Bacillus anthracis in a proteid medium, to which so much vinegar or any other acid has been added as makes it decidedly acid, it will be found that the spores do not germinate."

I have recently had occasion to object to the use of the terms antiseptic and germicide as synonymous, and the confusion resulting from such a misuse of the term *antiseptic* is exemplified in the above quotation. No one familiar with the present state of knowledge upon the subject would think of inferring that mercuric chloride is a germicide in the proportion of 1 : 300,000, because anthrax spores do not germinate in culture-fluids containing this amount. But an agent which prevents the development of putrefactive bacilli is an antiseptic, for putrefactive decomposition is prevented by such an agent as well as by one which kills germs. A germicide is necessarily an antiseptic, but an antiseptic is not necessarily a germicide. Thus alcohol, chloride of sodium, borax, sulphate of iron, and many other agents constantly used as antiseptics, do not in the most concentrated solutions destroy the vitality of the spores of bacilli, and consequently are not germicides.

The statement made by Klein that "perchloride

[1] The Practitioner, Lond., Oct. 1884, p. 251.

of mercury even of the strength of 1 per cent. is not a germicide any more than vinegar" is opposed by the experimental evidence reported *in detail* by Koch, and by my own extended experiments with this agent. I am convinced that there must have been some defect in Klein's method of working, and that the spores which killed his guinea-pigs had not been fairly exposed to the action of the disinfecting agent. He says:

"I have tried the action of a number of substances in common use as antiseptics (*e. g.*, Calvert's fluid, pure terebene, phenol 10 per cent., perchloride of mercury 1 per cent.), on the spores of Bacillus anthracis, exposing these in comparatively large quantities to the above fluids (the two being well mixed) for twenty-four hours, and then inoculating guinea-pigs with them (spores and antiseptic). The animals died with symptoms of typical anthrax, the blood teeming with the Bacillus anthracis."[1]

The very definite evidence from various sources, a portion of which will be given below, as to the power of mercuric chloride to destroy the spores of anthrax in much weaker solutions than that used by Klein, and in a much shorter time, justifies the suspicion that these guinea-pigs died from accidental inoculation with spores not subjected to the action of the disinfectant. This suspicion is further justified by Klein's account of the frequent accidents of this kind which have occurred in his laboratory. Among other examples of this given in the work already referred to is the following:

"Another gentleman working in the laboratory of the Brown Institution intended to inoculate several guinea-pigs with human tubercles. For this end he mashed up in a saline solution, in a clean mortar, a bit of human lung studded with tubercles. He did this in my room on the same table on which I was working with anthrax. One of these guinea-pigs, inoculated with human tubercle, died before the second day was over of typical anthrax. Its blood was teeming with the Bacillus anthracis. Such an accidental anthrax in guinea-pigs inoculated with tubercle occurred several times. . . I myself had the following accidental contaminations." . . .[2]

We are not here directly concerned with the restraining influence of mercuric chloride upon the development of anthrax spores, but having made some recent experiments in this direction which fully confirm the results previously reported by Koch, I may be excused for referring to the matter, especially in view of the therapeutic and sanitary possibilities which suggest themselves in connection with this inhibiting action of corrosive sublimate in very dilute solutions. From a sanitary point of view, it is evident that an agent which is capable of preventing the development of disease germs in cesspools and privy-vaults in the proportion of 1 : 300,000 [*i. e.*, one pound costing 50 cents would inhibit the development of anthrax spores in 300,000 pounds of a suitable culture-fluid] has an interest for health officers quite independent of the interest which attaches to it as a potent germicide in stronger solutions.

[1] Op. cit., p. 253.

[2] Microörganisms and Disease. The Practitioner, Lond., Aug. 1884, p. 110.

Experiment, Dec. 22, 1884.—Mercuric chloride was added to a sterilized culture-fluid in the proportion of 1 : 100,000, 1 : 200,000, and 1 : 400,000, and two culture-flasks were filled from each solution. These flasks were then inoculated with anthrax spores from a pure culture, and another flask not containing the mercuric chloride was inoculated to test the stock. At the end of 24 hours the last-mentioned flask contained an abundance of anthrax filaments, the others remained clear. At the end of 48 hours the two flasks containing the bichloride in the proportion of 1 : 400,000 contained flocculi of anthrax filaments, and the others remained clear.

Davaine found that the virulence of serum containing anthrax bacilli, obtained from the subcutaneous cellular tissue of an animal recently dead, is destroyed by adding to it corrosive sublimate in the proportion of 1 : 150,000.[1] In this case no spores are present in the material.

The restraining power of this agent is not so great for the spores of *B. subtilis* as for those of anthrax. This was shown by an experiment made upon the same date as that above reported. At the end of 24 hours after inoculation with spores a mycoderma of *B. subtilis* had formed in solutions containing 1 : 100,000, and in 48 hours the same result had occurred in two flasks containing 1 : 50,000.

The inhibiting power of this agent is still less for microörganisms in active multiplication. Thus in my experiments reported in the *Am. Journal of the Med. Sciences*, April, 1883, the development of micrococci was prevented by 1 : 30,000 to 1 : 40,000. I have recently repeated these experiments with a similar result. To destroy the vitality of the same micrococci, as proved by their failure to grow in culture-fluids required 1 : 20,000, while the bacteria in broken-down beef-tea, containing spores, were destroyed by 1 : 10,000. According to Koch, mercuric chloride in the proportion of 1 : 1000 destroys all spores in a few minutes, and in weaker solutions—up to 1 : 10,000—he has shown by culture and inoculation experiments that this agent destroys the vitality of anthrax spores.

The results of his culture and inoculation experiments are not, however, entirely in accord, and it seems probable that failure to develop upon the surface of a solid culture-medium after ten minutes' exposure to 1 : 20,000 may have been due to the restraining influence of a small amount of bichloride not removed by the washing in alcohol which was resorted to for the purpose of getting rid of this complication. Fluid cultures possess an evident superiority for such experiments as this, for when a very small quantity of spore-containing material is introduced into flasks containing a large quantity of culture-fluid the disinfecting agent is diluted beyond any possibility of interfering with the success of the experiment. Moreover when spores fail to develop in such fluid-cultures it is easy to prove that the failure relates to loss of vitality on the part of the spores, and not to the presence of an inhibiting agent. This

[1] Recherches sur le traitement des maladies charbonneuses chez l'homme. Bulletin de l'Acad. de Méd., 17 Juillet, 1880, p. 557.

I am in the habit of doing by inoculating the same culture-fluid with other spores not disinfected, and the rapid development of these is satisfactory evidence that in the first experiment failure to develop was not due to the small amount of mercuric chloride introduced in the inoculation with disinfected spores.

The view that in Koch's surface-cultures the inhibiting influence of the bichloride came into play, is sustained by his own inoculation experiments and by my culture experiments reported below. Thus we are informed[1] that three mice were inoculated with anthrax spores, attached to strands of silk thread, which had been exposed for ten minutes to solutions of the strength of 1 : 10,000, 1 : 20,000, and 1 : 50,000. All of the mice died of anthrax, but while the one inoculated with the strand exposed to 1 : 50,000 died in the usual time—on the second day—the one inoculated with 1 : 20,000 did not die until the fourth day and the one with 1 : 10,000 not until the fifth day.

That anthrax spores may survive exposure to a solution of 1 : 10,000 for a longer period than ten minutes is also shown by the following experiments.

Dec. 18, 1884.—A *small quantity* of a culture-fluid containing anthrax spores was exposed for *one hour* to mercuric chloride in the proportion of 1 : 10,000. No development of anthrax bacilli occurred in a culture-flask inoculated with these spores, but in another experiment, made at the same time, in which the proportion of the disinfectant and the time of exposure remained the same, and in which a *much larger quantity* of the spore-containing culture-fluid was used, there was an abundant development of anthrax bacilli in the inoculated culture-flask.

It is evident that in this experiment a material change in the conditions was made, although the time of exposure, and the amount of the disinfecting agent present, were the same in both cases, and that in experiments of this kind the amount of material to be disinfected must also be taken into consideration. In other words, a few germs may be destroyed by a comparatively dilute solution of the disinfecting agent, while stronger solutions will be required for the destruction of a large number of germs contained in the same amount of material. Again it is true of mercuric chloride as well as of oxidizing disinfectants, such as potassium permanganate and the hypochlorites, that the quantity of non-living organic material present will also materially influence the result. This is illustrated by my experiments reported below in which semi-solid feces was the material subjected to the action of the disinfectant.

The spores of *B. subtilis* are destroyed by about the same proportion of mercuric chloride as is required to kill anthrax spores.

Experiment, Dec. 22, 1884.—A small amount of a culture-fluid containing the spores of *B. subtilis* was exposed to the action of a solution of corrosive sublimate of the strength of 1 : 10,000, for 30 minutes; a like amount was exposed for 1 hour, and a third portion for 2 hours. Two culture-flasks were inoculated with spores from each. At the end of 24 hours those inoculated with the material exposed for 30 minutes showed an abundant development of *B. subtilis*, and the others remained clear.

The importance of the time of exposure to the action of the disinfecting agent, which is clearly brought out in the above experiment, is very well illustrated by the experiments on vaccine virus reported by Dr. W. J. Miller, of Dundee.

"I have made fourteen observations with this agent on vaccine. In one of these, it was tested in the following manner: I placed half the contents of a well-filled tube on a glass slide, and after it dried, covered it with some perchloride solution (1 in 1000), and after allowing it to lie for ten minutes, washed off the perchloride gently with water, so that the film of vaccine remained; this was then rubbed up with water, and put in a tube for use. The product entirely failed to take, while the other half of the same specimen of lymph produced a good result. Another specimen was mixed with an equal quantity of the same solution (1 in 1000), and was used an hour thereafter, disinfection being complete. Two trials were made with the same mixture, prepared immediately before use; two, after an interval of three minutes, and one, after fifteen minutes; and in all five, the lymph was uninjured. Five experiments were made with a solution of 1 in 500, and vaccine in equal proportions [= 1 : 1000.—G. M. S.], mixed respectively, immediately before use, a few minutes, three minutes, three minutes, and five minutes; and in all, the lymph was in no way affected. Two observations with lymph, and a still stronger solution, 1 in 250, in equal proportions, mixed immediately before use, gave the same negative result."[1]

According to Arloing, Cornevin, and Thomas, the activity of dried virus of symptomatic anthrax is destroyed by mercuric chloride in the proportion of 1 : 5000.

Jalan de la Croix found that the bacteria in beef *bouillon* were destroyed by 1 : 6500, but that the proportion required to destroy bacteria in a beef infusion made without heat was 1 : 2525.

It is evident that in the absence of precise information, as to time of exposure and other essential conditions, these results cannot be compared directly with those reported by other observers in which the material tested or the conditions of the experiment were different.

In the writer's experiments reported in the *American Journal of the Medical Sciences* for April, 1883, the bacteria in broken-down beef-tea (old stock exposed in the laboratory for a long time) were destroyed by two hours' exposure to mercuric chloride in the proportion of 1 : 10,000, the amount of material exposed to the action of the disinfecting agent being comparatively small.

Extended experiments upon the disinfection of tuberculous sputum have been made by Schill and Fischer, and are reported in their paper published in the second volume of the *Mittheilungen aus dem Kaiserlichen Gesundheitsamte*. In these experiments, the test of disinfection was failure of the material to produce tuberculosis when inoculated into susceptible animals.

In a first series of experiments with *dried* sputum,

[1] Mitth. a. d. k. Gesundheitsamte, I. p. 277.

[1] The Practitioner, Lond., Oct. 1884, p. 265.

which had been kept for several months, a negative result was obtained in every case from the following inoculations: Two guinea-pigs inoculated with material exposed for twenty-four hours to 1 : 1000; three with material exposed for twenty hours to 1 : 2500; and three with material exposed for twenty hours to 1 : 5000.

In another series of experiments with *fresh* sputum, in which the sublimate solution and the material to be disinfected were used *in equal amounts*, tuberculosis resulted in all of the test-animals. Three of these were inoculated with material exposed for twenty-four hours to 1 : 2000 (*i. e.*, equal parts of sputum and of a 1 : 1000 solution), and three to material exposed for twenty-four hours to 1 : 1000.

The failure to disinfect in these experiments was probably due to the fact that the viscid mass of sputum was not penetrated throughout by the disinfecting agent. In the successful experiment with dried sputum, the amount of material used was no doubt much smaller, and its physical condition (pulverized?) such as to insure the action of the disinfectant upon every portion of it.

In a previous paper (THE MEDICAL NEWS, Jan. 10, 1885, p. 34), the writer has recommended the use of a solution containing 1:500 of mercuric chloride and 1 : 500 of potassium permanganate as an efficient disinfectant for sputum and for the discharges of patients with typhoid fever and cholera. The experiments of Schill and Fischer, which I had not read when this recommendation was made, indicate that it will be necessary to use some other agent when the object in view is to destroy the infective virulence of tuberculous sputum. And, in general, it will no doubt be better to use an oxidizing disinfectant, such as the hypochlorite of soda, when the germs to be destroyed are embedded in masses of albuminous material. For such masses are disintegrated and destroyed by oxidizing agents, whereas corrosive sublimate has the opposite effect, in consequence of its power of combining with and coagulating albuminous material. For liquid fecal discharges, however, our recommendation is sustained by the experimental evidence.

The following experiments have been recently made: The standard solution above referred to—mercuric chloride and potassium permanganate, of each 1 : 500—was diluted one-half, and mixed with an equal quantity of broken-down beef-tea (= 1 : 2000). After exposure for two hours, the contained germs had lost their vitality, as proved by culture-experiments.

A more difficult test was the following: The standard solution was diluted one-half, and mixed with semi-solid feces in equal quantity, well-mixed by stirring. Two culture-flasks were inoculated from this at the end of 30 minutes, two more at the end of 1 hour, and two at the expiration of 2 hours. One of the flasks inoculated at the end of an hour broke down, the others remained clear. In the case of the flask which broke down, it is probable that some little mass of material was introduced which had not been thoroughly penetrated by the disinfecting agent. When the standard solution was diluted with three parts of water, and added to an equal amount of broken-down beef-stock (= 1 : 4000), two hours' exposure failed to prevent the subsequent development of the contained spores in a sterilized culture-fluid.

The experimental data herein recorded seem to justify the following conclusions:

Mercuric chloride, in aqueous solution, in the proportion of 1 : 10,000, is a reliable agent for the destruction of micrococci and bacilli in active growth not containing spores; and in the proportion of 1 : 1000 it destroys the spores of bacilli, provided that the microörganisms to be destroyed are fairly exposed to its action for a sufficient length of time.

A standard solution of 1 : 1000 may be safely recommended for the disinfection of bedding and clothing which can be washed; for washing the floors and walls of infected apartments; for disinfecting the hands and instruments of surgeons and gynecologists; and as a disinfecting wash for superficial wounds or mucous surfaces. For continuous application to wounds, etc., a solution of 1 : 10,000, or less, should be effective.

A standard solution of 1 : 500, with the same quantity of potassium permanganate, may be safely recommended for the disinfection of liquid fecal discharges, and other fluid material supposed to contain "disease germs," provided the time of exposure is not less than two hours, and the quantity of material to be disinfected is not in excess of that of the standard solution used.

SUCCESSFUL TREATMENT OF A CASE OF TRIGEMINAL NEURALGIA WITH NITROGLYCERINE.

BY S. P. DEAHOFE, M.D.,
OF POTSDAM, OHIO.

THE successful treatment of the following case renders it of sufficient interest to merit reporting.

H. J. A., aged 55, a farmer, with whom I was personally acquainted, family history good, came to my office, September 27, 1884, with the following history:

He had suffered pain, of a paroxysmal character, in the right side of the tongue for the past four years. The paroxysms of pain had increased in frequency and severity, so that when I saw him he had as many as half a dozen or more attacks in an hour, the pain "darting in the tongue like a knife," to use the patient's expression, interfering with mastication and also with his speech, so that he would be compelled to stop talking until the pain ceased, which would be in a few seconds. There was also marked spasm of the facial muscles of the same side of the face, the mouth being drawn to the right side. The teeth remaining were perfectly sound. His family physician had treated him for "paralysis of the tongue, due to his teeth," to use the doctor's own language, with various remedies. He had also been treated from time to time by a number of other physicians, both regular and irregular, all making similar diagnoses excepting one, who called it neuralgia.

I diagnosticated neuralgia of the gustatory branch of the trigeminus, and informed the patient of the

uncertainty of medicinal remedies in that affection, and the results of the operation of neurectomy. I concluded to try a few medicines first, and if they failed, then to perform neurectomy. Accordingly, I prescribed aconitia (Duquesnel's), in gradually increasing does, for two weeks, but to no purpose, the paroxysms still increased in number and severity.

The patient, becoming very much discouraged, then demanded an operation, refusing to take any more medicine. I then requested a consultation with Dr. J. C. Reeve, of Dayton, Ohio. The day for consultation was set; but being called to the country, the patient went to see Dr. Reeve in my absence. The doctor agreed with me in my diagnosis, and induced the patient to continue medicinal remedies yet awhile, giving him a one per cent. solution of nitroglycerine, concluding, as he afterward informed me, that the lesion was central.

In a few days, the patient reported to me a little better. I accordingly had the solution continued, in doses of one minim three times a day, with the following results:

After taking the solution two weeks, he was completely relieved. He then neglected taking it for a few days, when the pain returned, but not so severe as before. I then ordered him to continue its use. After taking the solution sixteen days more the patient was again free from pain and it has not returned since, and he was able to eat and talk as well as ever. He also says his mind and memory are far better; that his taste, which was much blunted before taking the remedy, is now normal; and that his eyes are so much improved that he can now read print without his glasses, which was difficult to read with them before taking the solution—in fact, he says he feels like a new man.

MEDICAL PROGRESS.

Furuncle of the Sebaceous and Sweat Follicles.—Dr. Josef Rabitsch, of Cairo, gives the following points of differential diagnosis between furuncle of the sebaceous follicles and the same disease in the sweat glands:

1. Sebaceous furuncle appears only on those parts of the body supplied with sebaceous glands.

2. The overlying skin is very red and inflamed, and the swelling is conical in shape.

3. At the end of four or eight days, there is an exudation through a crater-like opening.

4. After the discharge of the exudation, the resulting excavation is symmetrical and covered with healthy tissue, and cicatrizes very rapidly.

5. It may appear at any season.

Furuncle of the perspiratory glands:

1. Appears on all parts of the body, even upon the palm of the hand and sole of the foot.

2. The swelling is globular, and the overlying skin of a bluish-red color.

3. It opens in from eight to fourteen days, or later, at the point of its original appearance, or near by it, after necrosis of the skin and destruction of the adipose tissue.

4. The excavation, after the discharge of its contents, is unsymmetrical, and shows little inclination to heal.

5. It appears almost invariably in hot seasons of the year.—*Wien. med. Wochenschr.*, Dec. 13, 1884.

An Operation for Œsophagostomy.—At a late meeting of the Medico-Chirurgical Society of Edinburgh, Mr. Chiene showed a woman, æt. 32, on whom he had performed the operation of œsophagostomy. She suffered from a tumor situated behind the box of the larynx, which it was at first hoped was specific, but anti-specific remedies had failed to produce any effect. When she was unable to swallow, and was dying of inanition, the operation of œsophagostomy was proposed in preference to gastrostomy. Mr. Chiene thought he had made a slight improvement on the ordinary method of opening the œsophagus, by first incising the muscles—the anterior fibres of the sterno-mastoid and the posterior fibres of the sterno-hyoid and sterno-thyroid. By so doing, the access to the œsophagus was rendered much easier, as was also the stitching of the mucous membrane to the skin, the tension being reduced. The tumor had diminished since the operation was performed, and if she improved in weight, an attempt might be made to remove it. She was easily fed by the new mouth in the neck, the only disadvantage being the want of saliva.—*Edinburgh Medical Journal*, January, 1885.

A New Operation for Resection of the Stomach.—The *Wien. med. Wochenschrift* contains an account of a modified operation for resection of the stomach which Herr Billroth lately performed. After performing gastro-enterostomy according to Wölfler's method, he removed a carcinoma the size of a fist, cut through the duodenum beyond the carcinoma, and sutured the proximal end. The stomach was then opened above the cancer (about the middle), and the distal end of the duodenum sutured in the opening. The food entering the stomach accordingly passes into the far end of the duodenum.

This method of operation is applicable in such cases in which the extent of carcinomatous infiltration is so wide that union of the remaining portion of the stomach with the duodenum is not possible.

The patient endured the operation, which lasted more than an hour, well, and the day following was in good condition. At first he vomited the water which he drank, but shortly took milk and wine with relish. His appearance was better and pulse stronger and fuller than before the operation.—*Deutsche med. Wochenschrift*, Jan. 22, 1885.

The Therapeutic Effect of Caffeine.—Curschmann, in the *Deutsche med. Wochenschr.* of January 22, 1885, summarizes the therapeutic effect of caffeine as follows:

1. Caffeine and its salts are well tolerated, and even in large doses (30 grains per day) are harmless remedies.

2. Caffeine in large doses, 15 to 30 grains per day, has in many cases a pronounced diuretic effect, which is dependent upon the elevation of the arterial pressure. The movements of the heart become more regular, while a slowing of the pulse, worthy of mention, because frequently found, is absent.

3. This want of parallelism between the elevation of the aortic pressure, and a diminution of the frequency of the pulse, does not permit the action of caffeine and digitalis to be considered identical. It is, therefore, not established that caffeine is to be considered as an agent to regulate the heart, in the same sense as digitalis.

4. The diuretic operation of caffeine is no quicker, and frequently not so continuous as the corresponding dose of powdered digitalis.

Relative to a cumulative action of the drug, Curschmann, in very many cases in which large or long-continued doses were administered, has observed no such effect. Sometimes vomiting, malaise, and headache are observed, and some persons are so uniformly unfavorably affected in this manner, that the use of the drug is contraindicated.

Permanent Surgical Dressing.—At a late meeting of the Academie de Médecine de Paris, M. Marc Sée read a paper upon a method of permanent surgical dressing. When the wound is at the point which is to be sutured, M. Sée arrests the flow of blood as thoroughly as possible, at first by means of a catgut ligature and then by the aid of a light insufflation of powdered subnitrate of bismuth. When all oozing has ceased, he makes, when the wound has a certain extent, a number of catgut sutures and then introduces tubes of red caoutchouc to insure drainage, The wound is again treated with powdered bismuth, and is then covered with phenolized dressing, in which is enclosed a small quantity of corrosive sublimate. The dressing is kept in place by gauze bands, over which is applied a rubber band. The tubes are withdrawn at the end of three or four days, and the dressing is not removed for fifteen days or three weeks, or when cicatrization is complete. —*Le Progrès Médical*, Jan. 10, 1885.

The Antiseptic Use of Iodoform.—Dr. Mosetig-Moorhof, in the *Wien. med. Presse* of Jan. 4, 1885, cites the various preparations of iodoform useful in different conditions:

(*a*) The powdered iodoform.

(*b*) Iodoform stick, elastic or stiff, according to the use to which it is to be applied, prepared with gelatine, gum acacia, or cacao butter, for introduction into fistulæ, by which they are kept open, and a passage maintained for the exit of discharges.

(*c*) Iodoform gauze, obtained by the saturation of gauze by a thirty or fifty per cent. ethereal solution of iodoform without addition of adhesive material.

(*d*) Iodoform emulsion, containing ten to fifty per cent. of iodoform, ten per cent. of water, and twenty-five per cent. of gum tragacanth. This form is applicable to compound fractures, to joint cavities, and to cold abscesses.

Iodoform in the formula: iodoform, 1 part; benzol, 9 parts; ol. vaselini, 11 parts, is valuable for parenchymatous injection in struma and uncaseified lymph glands, with excellent results.

It is also valuable in burns when applied in the form of iodoform gauze moistened in a mixture of glycerine and water, 1 to 3, and covered with wadding surrounded by an impermeable gutta-percha sheath.

No evidences of poisoning have appeared with this application, even when it has been used in burns of great extent.

Use of Cocaine in Lithotrity.—Lithotrity with rapid evacuation of the fragments (Bigelow's operation) was performed recently at St. Peter's Hospital with perfect success. The bladder was injected with a half ounce of a four per cent. solution of cocaine, and the operation was begun and completed painlessly in a quarter of an hour.—*Lancet*, Jan. 17, 1885.

Treatment of Phthisis by Arsenic.—Dr. Klempner, after a lengthy discussion on the use of arsenic in phthisis, arrives at the following conclusions:

1. Arsenic seems to exert a good effect upon the general nourishment and condition of phthisical patients.

2. A trial of it appears indicated in all phthisical cases in which no special contraindication exists.

3. A contraindication may be:

(*a*) Special idiosyncrasy against the remedy which now and then exists.

(*b*) Prominent tendency to hemorrhage.

(*c*) Organic disease of the intestinal tract and tubercular disease of the colon.

(*d*) Disease of the kidneys through which the regular excretion of the poison from the body is rendered difficult.—*Med. Chirurg. Centralbl.*, Jan. 16, 1885.

Cola.—After an exhaustive therapeutic and physiological study of the properties of cola, Dr. Monnet reaches the following conclusions as to its nature and value in medicine:

1. Cola, on account of the caffeia and theobromine which it contains, is a tonic to the heart, quickening its beat, increasing its power, and steadying its contraction.

2. In the second phase of its action, like digitalis, it regulates the pulse; under its influence, the pulsations become fuller and less frequent.

3. As a corollary to its action upon the blood pressure, there is increased diuresis, whence cola is usefully employed in affections of the heart complicated with cardiac dropsy.

4. Experiment seems to show that cola, which causes energetic contraction of the heart and increases the contractility of the muscles of organic life, on the contrary, exercises a paralyzing effect upon striated muscles when employed in toxic doses.

5. It prevents tissue waste and diminishes the production of products resulting from the destruction of nitrogenous elements (urea), and probably exercises a special action upon the nervous system.

6. In virtue of the principles it contains, it is a powerful tonic, and its use is indicated in anæmia, in chronic debility, and in convalescence from serious diseases.

7. It favors digestion, either by augmenting the secretions of the stomach, or by its action upon the muscular coat of the stomach, which is rendered less atonic in certain forms of dyspepsia. Under its influence anorexia disappears, and the digestive functions are regulated.

8. Finally, it is a remedy which has given markedly beneficial results in chronic diarrhœa, and in certain cases of sporadic cholera (Huchard, Duriau), without its being possible to explain its action physiologically. —*Bulletin Général de Thérapeutique*, Jan. 15, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PHILADELPHIA.

SATURDAY, FEBRUARY 21, 1885.

LAPAROTOMY FOR GUNSHOT WOUND OF THE SMALL INTESTINE.

IN the issue of THE MEDICAL NEWS for last week may be found an important contribution to the practical surgery of gunshot wounds of the intestines, from the pen of DR. W. T. BULL, of New York. A man, 22 years of age, was shot with a pistol of thirty-two calibre, the ball entering the abdomen near the umbilicus. At the expiration of seventeen hours, when the pulse was 102, the respiration 30, and the temperature 100.2° F., and when there was severe pain, with slight tenderness, Dr. Bull, under strict antiseptic precautions, opened the belly by a median incision extending from the umbilicus to just above the pubes. About two pints of bloody serum, containing small clots, escaped, and the intestines and mesentery showed marked evidences of peritonitis. An incised wound of the serous coat alone, made by the scissors, was tied with catgut, seven perforations were closed with Lembert's suture, iodoform was rubbed over the lines of union, and the bullet, lodged in the upper surface of the sigmoid flexure close to its mesenteric border, was removed, and the perforation united with three stitches. The man was enjoying excellent health at the expiration of three months.

The case thus briefly outlined is the first successful one of its kind on record. Kinloch, of Charleston, in 1882, did a tentative laparotomy, and sutured five pistol-shot wounds of the small intestine. On death, in thirty-two hours, two additional perforations were found to have been overlooked. In a third case, Jordan Lloyd, of Birmingham, opened the belly for suppurative peritonitis on account of a similar injury. The intestine, perforated in two places, was stitched to the abdominal wound, but the patient succumbed in two hours.

In the discussion which followed the reading of Dr. Bull's paper before the New York Surgical Society, there was a disposition to question the propriety of the operation, first, because of the asserted absence of signs of perforation or of peritonitis; and, secondly, because it was assumed that the fibrinous effusion would have sufficed to close the perforations and rendered spontaneous recovery possible.

With regard to the first objection, it may be asserted that it had no foundation in fact. On the admission of the patient, half an hour after the reception of the injury, the pulse was 96, the temperature 97.8°, and the respiration 18. When laparotomy was resorted to, the pulse was 102, the temperature 100.2°, and the respiration 30; the belly, moreover, was tender, the pain was severe, and the patient had vomited. Surely these symptoms indicated commencing peritonitis, and it would have been a grave error to have waited until they became more intense. The second objection was equally groundless. Spontaneous recovery after gunshot wounds of the small intestines is exceedingly rare, if not, indeed, questionable. Otis states that there is not a single incontestable example of recovery achieved by the unaided efforts of nature on record, and the case reported by Andrews, of Chicago, in the *Weekly Medical Review*, No. 22, 1884, does not invalidate the result of his investigations. In this case, a boy sixteen years of age was shot with a twenty-two calibre pistol-ball, which entered the belly in the linea alba an inch above the umbilicus. The treatment consisted of starvation and opium, the ball passed per anum in a week, and recovery was rapid. There is no evidence, however, that the small intestine was opened in this instance, it being far more probable that the stomach or transvere colon was the seat of the injury.

Not only has ample experience in the human subject shown that these lesions are almost necessarily mortal, but experiments upon the lower animals have served to explain why spontaneous recovery is out of the question in wounds of the magnitude met with by Dr. Bull, several having been half an inch in diameter. In his monograph, entitled "An Experimental and Critical Inquiry into the Nature and Treatment of Wounds of the Intestines," published in 1842, the late Professor Gross states that when the opening is half an inch in extent, there is almost invariably an escape of fecal matter, speedily followed by peritonitis. If such an untoward result attends incised wounds six lines long, we may naturally infer that fecal extravasation must ensue from a gunshot perforation six lines in diameter, since the

contraction of the opening and the eversion of the mucous membrane, which are nature's resources in closing minute wounds, are absent in lesions produced by projectiles, even of small calibre, which, as shown by the experiments of Parkes, published in THE MEDICAL NEWS for May 17, 1884, produce extensive and severe lacerations.

In view of the grave prognosis of shot wounds of the small intestines, which are, as a rule, multiple, we are firmly convinced that the expectant treatment should henceforth be entirely abandoned. In all cases, as soon as the diagnosis of penetration of the abdominal cavity has been established, an exploratory laparotomy is demanded, whether signs of peritonitis be absent or present. If the intestine be found to have escaped, little, if any, harm will ensue, whereas if the gut be opened the wound can be closed with sutures, and hemorrhage arrested, thereby materially enhancing the chances of recovery. When the perforations are in close proximity to each other, the affected portion of the gut should be excised, the divided ends be approximated, and the coil be returned into the belly. The formation of an artificial anus, as attempted by Lloyd, is not desirable.

In THE MEDICAL NEWS for October 18, 1884, we called attention to Kocher's successful laparotomy and enterorrhaphy for a pistol-shot wound of the stomach; to an equally successful similar operation by Mikulicz for peritonitis, the effect of perforating ulcer of the ileum; and to a laparotomy by Krönlein for peritonitis, resulting from perforation of the vermiform appendix, with resection of the latter. In addition to these cases, which serve to illustrate what should long since have been an established principle of treatment, Tiling has recorded in the *St. Petersburger medicinische Wochenschrift*, No. 44, 1884, a recovery after laparotomy for a penetrating knife wound of the stomach. The peritoneal cavity was filled with blood, and a wound, two-fifths of an inch long, in the posterior wall of the viscus was closed by three sutures passed through the muscular coat, and four points of Lembert's suture carried through the serous coat. The presence of a wound in so unusual a situation, the knife having entered through the anterior wall of the belly, shows that the posterior wall of the stomach presents forward when it is distended by food. The patient, a male, 19 years of age, vomited immediately after the reception of the injury, through which the escape of the contents of the stomach into the peritoneal cavity was prevented.

From these facts we are led to the belief that not only is suturing, with or without enterectomy, indicated in gunshot wounds, but that it should also be resorted to in all perforations, be they traumatic or pathological, of any portion of the gastrointestinal tract.

CHOLERA PROSPECTS.

THE great majority of American physicians and sanitarians are of the opinion that it is rather more than an even chance that Asiatic cholera will be brought to our shores in the course of the present year, and this opinion is based on the history of previous epidemics. As the course of the disease in Europe last year was somewhat different from that which it has followed in previous epidemics, and as it has not yet appeared in those regions from which the tide of emigration sets most strongly towards the United States, the danger can hardly be said to be immediate and pressing. Still, there is no doubt that the danger is a very real one, and that those who are charged with the duty of caring for the public health are incurring grave responsibility if they hesitate or delay to take the precautions which all are agreed will be most efficacious in preventing the admission or limiting the spread of this disease.

We are sorry to be compelled to say that for the most part they are doing very little. As yet Congress has taken no action in the matter, and there is not the least probability that it will consider any of the bills which are now before it, for the establishment of a National Health Board or Bureau. What little power the present National Board possessed under the so-called Quarantine Act of 1879 has disappeared with the lapse of the four years during which alone that act was to remain in force.

It is true that if sufficient funds are granted to the Board, this want of power will not be greatly felt. The composition of the Board has changed to a considerable extent since it did its best work in 1879–80, and the action of the Conference of State Boards of Health at Washington, in recommending to Congress a Board organized on a totally different principle, shows that it has, to some extent at least, lost the confidence of the sanitary authorities of the country. As, however, the active support of these authorities did not seem to be of much assistance to the Board in securing appropriations from Congress, it is probable that the loss of this support will not do the Board much harm.

It is quite probable that Congress, before adjournment, will appropriate half a million of dollars to be used by the President as an epidemic fund, and as the members of the National Board of Health are decidedly in harmony, politically, with the incoming administration, it is quite likely that they will be able to induce the President to intrust it with the expenditure of the money, in which case the old friends of the Board will, for the most part, again take it into favor; which is probably the best solution of this part of the problem now possible.

But the action of Congress is of small importance as compared with what could be done by State and Municipal authorities, and yet many of these show

no signs of activity. Pennsylvania is still without a sanitary organization. Philadelphia still contains thousands of cesspools and privy vaults, and has the unenviable reputation of having the worst system of sewerage of any large city in the United States, with the exception of Baltimore. The soil of these two great cities, Philadelphia and Baltimore, is thoroughly saturated with organic matter by soakage from cesspools, vaults, and leaky sewers; and if it is true that cholera flourishes above such soils, their prospects are gloomy. It would be easy to specify many smaller cities and towns which are even worse prepared to meet Asiatic cholera than the two we have named, and which are doing nothing—waiting stupidly for the blow to fall. If it does come, we shall, no doubt, have a sort of sanitary revival; but what a pity it is that such a revival is not already in full blast. Asiatic cholera in this country means the loss of millions of money as well as of many lives. Five hundred deaths from the disease in Philadelphia will cause a loss to this city of more money than would give it an abundant and pure water supply and a thoroughly good system of sewerage twice over. There is little hope that our City Government will do anything; but is it not possible that there are two or three hundred intelligent citizens who have enough energy and enough at stake to induce them to take hold of the matter and compel some action?

VERSIONS AND FLEXIONS OF THE UNIMPREGNATED UTERUS.

The last and concluding lecture of Dr. Van de Warker's series upon versions and flexions of the unimpregnated uterus is given in this number of The News. These elaborate lectures require, as they certainly deserve, careful study for their proper appreciation. Probably no one else in the United States is so familiar with the literature of the subjects treated as is Dr. Van de Warker; his lectures constitute an important contribution to medical progress, and their preparation required extensive research, careful comparison, large experience, and wise judgment.

In connection with this subject, we desire to call attention to a few points in regard to which differences of opinion exist. Dr. Van de Warker adopts the view generally held, that lactation promotes uterine involution. Certainly, such opinion seems quite reasonable; nevertheless it did not receive the endorsement of Depaul, nor does it that of Charpentier, while Milsom claims to have proved that, so far from lactation promoting, it delays the involution of the uterus. Possibly there may be found a reason for this result in the fact that the woman who does not nurse is liable to a new pregnancy, and hence the necessity for the uterus being speedily restored to suitable condition, while a similar liability is much less in the nursing woman.

In the treatment of flexions of the uterus, Dr. Van de Warker rejects dilators, as well as Emmet's operation, to straighten and enlarge the cervical canal in anteflexion; he speaks of the latter as a formidable operation, and not free from danger, and that he has seen no good results from the few cases in which he has done it. He strongly advocates the stem pessary, and in this, is at one with Bantock, while many other authorities are opposed to this method—Dr. Emmet, for example, remarking in his well-known work: "As soon as the true condition comes to be appreciated, the use of the intrauterine stem will be abandoned as a most irrational instrument." Schultze, whose valuable work is almost essential for a complete study of these diseases, rejects stem pessaries in anteflexion, stating that it would be much more rational to shorten the contracted retrouterine ligaments by methodical tractions upon the neck, than to seek to restore the form of the uterus by mechanical means. Our own experience leads us to believe that the dangers of the stem pessary have been exaggerated; we doubt not that when the instrument is used with the precautions Dr. Van de Warker advises that the risk is very little. But the question as to their beneficial result is a larger one, that cannot be so readily answered. Possibly the truth lies in the mean, rather than in either extreme, and there may be an ultraism in the advocacy of the instrument, as well as too much conservatism in its rejection.

A DOCTOR'S BANK.

In a controversy which has lately appeared in one of our Southern contemporaries between a celebrated New York specialist and a visiting Georgia doctor, one of the subjects of a by-no-means amicable discussion is the propriety of displaying fees on the table of the consultant. The Georgia doctor thus narrates his grievance:

"On his left [the consultant's] is a pile of $20 bills held down by an ill-shapen stone. Just across this *exchequer for the public gaze* is the chair in which all visitors are peremptorily told to 'sit down.'"

To this impeachment, the consultant replies in the next issue of the journal as follows:

"As to my fees, I leave them on the table through the morning as they are paid by patients. I have no family practice, and most of those who consult me prefer to pay for each visit, as is a common practice in this city. I had several first patients every day, and there were, of course, several twenty dollar bills on the table every time Dr. —— came to my house."

It was, it must be confessed, a rather harrowing spectacle for a country doctor to see from his chair every time he raised his eyes a pile of $20 notes so

voluminous that a stone of any shape was required to keep them down. But he appeals, as we shall do, to the ethical side of this question. Appreciating his feelings on witnessing the spectacle of so much money, a part of the paltry gains of a single morning, we will attempt nevertheless to rise above the moral depression thereby occasioned, and ask our readers, Is it proper thus to display to the world the lucrative business of the medical practitioner? We can conceive that in the hurry of visits—indeed, we know—it is not always easy to dispose of the fast-accumulating bills in even our plethoric wallet. Yet it is quite possible to have a convenient drawer in which they can be speedily stored. In fact, one of those mysterious Jacks with a snapping mouth or protuberant belly, into whose depths good little boys are beguiled to bestow their pennies, may be utilized for the keeping of a doctor's twenty dollar fees. Very celebrated doctors have, however, hesitated to trust all contrivances of this kind, and have preferred to keep the money under their own eyes, as both safer and far more delectable. We are told that Ricord, the celebrated syphilographer, always allowed his Napoleons and sovereigns to accumulate on his table, chiefly, however, as a reminder to his patients that he expected immediate remuneration. That he, also, gratified himself with the sight of it, like the miser in "The Chimes of Normandy," is not improbable.

We can understand that displaying his fees, like the gambler's bank at Monaco, may have its uses to a canny doctor. But after all that can be said in favor of it, we must admit that it wears an air of charlatanry. It is an old trick, for we find that Hudibras's lawyer had

> ——— money placed for show,
> Like nest-eggs, to make clients lay,
> And for his false opinions pay.

THE USE AND ABUSE OF BATTEY'S AND TAIT'S OPERATIONS.

The restriction of an operation within proper limits is quite as important as its invention. He who devises a new operation is in danger of giving it undue importance, or if too modest, too wise, or too conservative in his nature to do so, he is sure to have followers who will exaggerate its value. Hardly a score of years have passed since bilateral division of the cervix uteri was done as often during a single month in Scotland, or in London, or in the United States, as it is now done in half a dozen years. Then one operator would boast of having performed it hundreds of times, now it is an almost forgotten operation, or at least rarely performed.

That which is known as Battey's operation was first done about thirteen years ago, and has been performed scores of times both at home and abroad. In some cases it has brought no good, in others death has followed, while in the majority it has resulted beneficially. But still, notwithstanding the limitations which Dr. Battey has assigned it, there is not entire agreement in the professional mind as to the cases which require it; we fail in the knowledge which can only come from large experience and continued observation, so that for a time at least, absolute rules cannot be laid down, but it is quite probable that even some of the limitations referred to are themselves but temporary and provisional, and will after a time be materially altered or entirely cast aside.

A similar remark may be made as to the operation known as Tait's, an operation which in this country is not so familiar to the profession as Battey's; the conditions which are alleged to require it are not so plain, and the diagnosis is more difficult. It is an operation, too, which finds no favor with some of the best London authorities, such as Sir Spencer Wells and Dr. J. Matthews Duncan.

Dr. W. H. Baker recently read a paper, with the title, "The Use and Abuse of Battey's and of Tait's Operations," before the Boston Society for Medical Improvement, which appears in a late number of the *Boston Medical and Surgical Journal*. He narrated four cases, in one of which he removed the ovaries for cystic disease, in another the uterine appendages for dropsy of the oviducts, while the other two, which were supposed to require Battey's operation, recovered without its being done. Of course this is too small a number to generalize from—a larger induction is needed to prove, although they may illustrate a truth.

One of Dr. Baker's conclusions is that these operations should be restricted to cases in which structural changes in the ovaries or tubes have been clearly made out, and when other suitable treatment has been unsuccessfully tried for months. He also holds that the removal of the uterine appendages may be necessary in some cases in which menstruation endangers the life or the mind of the patient, though no structural changes in these organs can be discovered. His third conclusion is that when diagnosis of cyst of the ovary is made, delay in ovariotomy increases the danger to the patient, and therefore the operation should be done at once. In regard to this point there doubtless is some difference of opinion, for it may be asked, Are we justifiable in doing an operation which may destroy a patient's life when her present health is perfect, and the cystic disease quite stationary? The final conclusion is that an exploratory incision may in some cases be warranted if it be impossible to make a diagnosis without such incision.

Dr. Baker's contribution renders some assistance towards assigning to these operations their proper

place, but a great deal more must be done before this end is accomplished.

In one of George Eliot's letters, to be found in the third volume of Mr. Cross's biography of that gifted woman, she refers to a remark which Prof. Huxley made on those good people of London, who have pursued him with false witness in their antivivisection zeal. He declares himself to be especially vexed with the "profligate lying of virtuous women."

This stinging phrase seems not inappropriate to the hermaphrodite organizations of the same kind in this part of the world.

REVIEWS.

In War Time. By S. Weir Mitchell, M.D. 12mo. pp. 423. Boston: Houghton, Mifflin & Co., 1885.

If the hard-working practitioner of medicine can ever afford to turn from the rugged and often unattractive ways of science into the pleasant paths of fiction, it is surely when the work which he selects is not only vastly entertaining in itself, but has a medical man for its hero and an eminent physician for its author. Judged from either standpoint, Dr. Mitchell's latest and most ambitious production is well adapted to excite and maintain the interest of the profession. Of the story itself, admirably conceived and well sustained throughout, we need not speak in detail, though we cannot avoid an allusion to the charming portraiture of the heroine, Mrs. Westerly, to whose graceful femininity the book owes much of its attractiveness. We know of few better pictures of the true woman—the lady—accomplished, well-bred, self-respecting, yet with a woman's follies and weaknesses delicately but clearly outlined. Meeting the attack of spiteful gossip with calm dignity or with trenchant sarcasm, but melting into warm sympathy at the woes of a friend; loving mildly and somewhat hesitatingly at first, but with increasing fervor as obstacles multiply and judgment opposes; pardoning freely a great weakness, but roused to unforgiving scorn by a lesser one which savors of dishonor, she carries with her, from first to last, a definite and charming personality, which would of itself save the book from any charge of dulness, and entitle it to a high place among those works of fiction which depend for their interest rather upon skilful delineation of character than upon plot or incident.

We have been, however, no less impressed with the portrait of the hero, and, through him, with the medical aspects of the story. Dr. Wendell, at the opening of the narrative, an assistant-surgeon in the U. S. Volunteers, is portrayed with such a vigorous, yet delicate touch, and his character, combining decided mental activity and fair literary and scientific ability with a fatal vacillation, and lack of persistent energy, is so logically and dramatically developed to its legitimate conclusions, both personal and professional, as to present a picture which, though the reverse of pleasing, is most artistic and impressive. Dr. Wendell will take his place at once, as by no means the least, among the noted medical personages of fiction, of whom there are few enough bearing any resemblance to the actual type which they are supposed to represent. Indeed, exclusive of Lydgate in "Middlemarch," and Dr. Leslie in Miss Jewett's delightful little story "A Country Doctor," they are almost invariably specimens of pseudo-scientific charlatanism, as Charles Reade's Dr. Sampson; of incredible and mysterious acumen, as Wilkie Collins' Mr. Speedwell; or of ridiculous impossibilities, as Miss Phelps' Doctor Zay. It is a great pleasure to welcome to our shelves a *real* doctor, even although he is only to serve as a warning or a rebuke.

The methods by which the gradual evolution of this character is shown, are admirable in their fidelity to truth; and the successive steps by which the almost excusable procrastination and equivocation, and the slovenly, though intelligent, professional work depicted in the first chapter, degenerate into the falsehood, the criminal carelessness, and the final dishonor of the closing scenes, constitute an inflexibly logical sequence which maintains the reader's unflagging attention. The interest, too, is sustained by the fact that, up to the point when Wendell's past cowardice when under fire is disclosed, one involuntarily hopes that the amiable and lovable side of his nature will finally triumph, and that our unavoidable sympathy will be permitted to develop into affection and respect; or that the *descensus Averni* will at least take an upward turn, and lead him to quarters more comfortable, even though undeserved, than those he seems destined for. After that disclosure, however, the correlation between his physical and moral weakness is so apparent, and the downward progress is so rapid, that we no longer hope against hope, but follow absorbedly, if not resignedly, the closing events of his career. Apart altogether from the interest of the story, however, which is greatly added to by the skilful delineation of several minor characters, notably Ann Wendell, Edward Morton, and Colonel Fox, the book is full of descriptive or reflective paragraphs, originating in the author's professional experience, and appealing strongly by their vividness and accuracy to the medical reader. Have we anywhere in so few words as graphic a picture of a death-bed as this?

"Charles Gray was lost even now to the world of loves and hates. Gaunt with past suffering, his cheeks flushed with moving spaces of intense purplish red, he lay on his back. His eyes, wide open, stared up at the ceiling between moveless lids, while the irregularly heaving chest and the dilating nostrils told of the closing struggle for the breath which is life."

Or as a corollary to that scene, and apropos of the consultation between Dr. Wendell and his superior, Dr. Lagrange, to which it gave rise, could we have a more terse and truthful explanation of what often seems to the laity medical heartlessness?

"The contrasts in a doctor's life are always striking. . . . These two men, coming from the every-day calamity of a death-bed, instantly set aside the emotions and impressions, which no repetition ever quite destroys for the most callous doctor, and began to discuss the scientific aspects of the disease with which they had been so vainly battling. They both felt, more or less, the sense of defeat which waits for the physician as he leaves the room of the dying—a keener discomfort than the unthinking public can well imagine; but both were able to lose it in their interest in that which caused it."

In an admirable description of the evolution of our medical service during the war the following paragraphs are worthy of special note:

"In all other lands medicine had places of trust, and even of power, in some way related to government; but with us, save when some unfortunate physician was abruptly called into public notice by a judicial trial, and shared for a time with ward politicians the temperate color of newspaper statements, he lived unnoted by the great public, and for all the larger uses he should have had for the Commonwealth quite unemployed. The war changed the relation of the profession to the State and to the national life, and hardly less remarkably altered its standard of what it should and must demand of itself in the future. Our great struggle found it, as a calling, with little of the national regard. It found it more or less humble, with reason enough to be so. It left it with a pride, justified by conduct, which blazoned its scutcheon with endless sacrifices and great intellectual achievements, as well as with a professional conscience, educated by the patient performance of every varied form of duty which the multiplied calls of a hard-pressed country could make upon its mental and moral life."

The temptation to quote increases as we turn over the leaves, but we must content ourselves with these extracts, which might be multiplied largely, but which will serve to demonstrate that Dr. Mitchell, in producing a work that may fairly be said to show a high order of imaginative and literary skill, has preserved his character as a thoughtful and keenly observant physician, and has thus enabled his medical readers to derive an increased pleasure from his skilful blending of fact with fancy.

SOCIETY PROCEEDINGS.

PHILADELPHIA NEUROLGICAL SOCIETY.

Stated Meeting January 26, 1885.

The President, S. Weir Mitchell, M.D., in the Chair.

Dr. H. C. Wood presented to the Society

THE FEET OF AN ATAXIC PATIENT ILLUSTRATING CHARCOT'S JOINTS.

The specimens were from the Mütter Museum of the College of Physicians, the feet of an ataxic patient that had been under his care at the University Hospital. He expressed the opinion that there was a close relation between this disease of the bones in ataxic cases and syphilis.

Dr. A. Sydney Roberts read, by request, a paper on

THE SPINAL ARTHROPATHIES.

(See The Medical News for February 14th, page 175.)

Dr. Morris J. Lewis reported

A CASE OF LOCOMOTOR ATAXIA WITH LOSS OF TEETH AND ALVEOLAR PROCESSES.

The following anomalous case of locomotor ataxia has been under my care for three months in the Episcopal Hospital. He is now under the care of Dr. Henry M. Fisher, who courteously allows me to use the notes of the case.

Mr. A., æt. 45, a well-marked ataxic for over five years, presents the following history, some points of which seem well worthy of record. Nasal catarrh exists in several members of the family, including himself. During the war he was wounded in the hip and ankle, slightly; the wounds healed kindly. He was confined for some time in Libby and Belle Isle Prisons, and since then has never felt strong. He denies having had syphilis. When 39 years of age he began to show the first symptoms of ataxia; these were diplopia, dizziness, and a staggering gait. One and a half years later he began to have lancinating pains in the extremities, and later in the bowels. Five years ago he began to have transient attacks of difficulty of hearing, and this has increased since then until about one year ago, when he became absolutely deaf.

He has always been constipated, and one year ago had slight difficulty in urination. Within the last seven months he has had severe gastric crises. Eyesight good until the last seven or eight months, except during the first year. Four years ago the symptom for which I present the case to-night, first appeared. This was a loosening and a subsequent falling out of the lower wisdom teeth. No pain nor discomfort preceded this, and the teeth were perfectly sound. In fact he had an uncommonly fine set of teeth. After this his teeth gave him no trouble until about seven months ago, when the same change began in the upper jaw, causing the loss of every tooth except the right first molar, which still remains firm.

The sequence of these events appears to be as follows: First, the teeth loosen, then the gums recede, showing in places the alveolar processes denuded, the teeth then fall or are pulled out by the fingers, and finally the alveolar processes separate in small fragments, with slight suppuration, or are detached in larger pieces. The gum then heals. The largest piece of bone thus separated shows the sockets of three incisor teeth, and a portion of a fourth. The teeth show no absorption of their fangs, and are almost without exception perfectly sound. About four months elapse between the loosening of a tooth and the final healing of the gum.

Other points of interest in this case are as follows: the patient is extremely pallid; he has the ataxic gait, although this is not very pronounced. He cannot stand with eyes closed. The knee-jerk is absent, and has been for at least four years. There is no anæsthesia of the feet or legs, and the patient localizes touch fairly; there is, however, some analgesia. There is no retardation of sensation. Examination shows external strabismus of both eyes. Pupils pin-point for near accommodation, and relax for distant vision; no reaction to light. Ophthalmoscopic examination shows left eye-ground normal, and but slight atrophy of nasal border of right disk. His sense of smell and of taste is good. There are no lesions in any of his joints to be detected.

Dr. Lambert Ott presented a case of

LOCOMOTOR ATAXIA WITH CHARCOT'S JOINTS.

S. H., aged 45 years, a travelling salesman. In 1866 he contracted chancre, no secondary symptoms following. In May, 1881, his present disease began with shooting pains in limbs and unsteadiness of gait. In November, 1883, I first saw him and diagnosticated his condition as locomotor ataxia. At the present time there is very little missing that goes to make up the

symptom-group of this disease. In December, 1883, about two and a half years after the beginning of his trouble, he noticed a swelling of his left ankle. In the morning it seemed less, and in the evening it had increased to such an extent as to cause difficulty in taking off his boot. He had no pain, no impediment in using the joint, and had it not been for the swelling he would not have taken any notice of it. He thinks the swelling reached its maximum in two weeks, and there has been no great variation since, except that in the evening it is slightly increased. At present his foot is moved normally, but when the back of the leg is grasped and extreme flexion made, crepitation is imparted to the hand; the swelling is confined to the inner and dorsal surfaces of the ankle-joint, and feels bony. The joint measures in circumference one and a half inches, the leg at midcalf one-half inch more than the opposite limb. There is no pain or tenderness on pressure or rough usage. He has been under treatment fourteen months, and has taken corrosive sublimate and chloride of gold and sodium. The electrical treatment at first was central galvanization and general faradization, and latterly the metallic brush, with the rapidly interrupted faradic current, with marked improvement.

Dr. W. W. Keen then read a note on the

COMPARATIVE EFFECTS OF ACTIVE VOLUNTARY EXERCISE AND OF PASSIVE EXERCISE BY MASSAGE, ON THE PRODUCTION OF ALBUMINURIA,

in which he called attention to one point of value in the use of massage, heretofore unrecognized.

A patient consulted him for relief from severe, constant, and long-continued pains in the calves of his legs. During the preceding year, he had walked, as a matter of exercise, nearly 2000 miles, and during the year before that had travelled around the world, making long rides and walks a marked feature of his trip. He found that he had an albuminuria, of from three to ten or fifteen per cent., which was curiously dependent upon exercise. This he tested in the following way: He put him in bed for three days, and examined specimens of urine passed at different times in the twenty-four hours. No albumen appeared. Immediately after the last examination, he dressed and walked a measured mile. Immediately on returning, he passed water which had about five per cent. of albumen. One hour later, it had still a trace; two hours after the walk, it was free. The next morning's urine was still free, but that passed after walking a mile had again about five per cent. of albumen. A few days later, massage was applied thoroughly for forty to fifty minutes by a most competent rubber. The urine immediately before and immediately after the massage was free from albumen.

This is a striking addition to Dr. Weir Mitchell's observations as to the resulting tissue-changes induced by massage, and especially shows its value as a means of passive exercise without deleterious effects through nervous exhaustion. Dr. Keen believed the value of the massage to lie in the resulting stimulation to the muscular tissue, and the promotion of its nutrition without such changes of blood pressure and vaso-motor tonus in the muscular coat of the vessels, as induced the curious albuminuria after voluntary exercise above noted. The very probable nervous origin of albuminuria, as shown by its frequency in cases of long-continued nervous strain, and by the researches of DaCosta and Longstreth, would seem, also, to have a new confirmation by this observation.

Dr. Keen's attention has been called by Dr. Mitchell to an article on "Albuminuria as a Symptom," by the late Dr. Calvin Ellis, in the *Boston Medical and Surgical Journal*, 1880, vol. xxv. p. 388. The following somewhat analogous cases are referred to by him: In one case (Dukes: "The Albuminuria of Adolescents," *British Medical Journal*, Nov. 30, 1878, p. 794), a young man's urine was normal when in bed. On rising and taking milk only, it would continue so; but after eating a piece of bread, the albumen would appear. As he improved while lying in bed, meat could be eaten without any change in the urine. While this would look to digestive changes as a cause, the so-called post-cibal albuminuria, the following cases are more positive evidences of the effects of exertion in the production of albuminuria:

Edlefsen (*Berl. klin. Wochen.*, Sept. 22, 1879) noticed in three healthy but anæmic men transient albuminuria after exertion. Leube (*Virchow's Archiv*, v. 72, p. 145) examined the urine of a large number of healthy soldiers in the morning, and found it normal, but after a five hours' march or severe exercise, in June, July, and August, with a temperature of 54° to 77° F., it contained albuminuria in sixteen per cent., though the amount was small and never exceeded one per cent., and there were neither casts nor blood corpuscles. This could not be detected at a later examination, between 4 and 6 P.M. The same was seen under similar circumstances in army officers in connection with scanty urine, and also in nervous persons. (Fürbinger, *Zeitsch. f. klin. Med.*, 1, p. 345.) "It is most natural to suppose that its presence was owing either to some variation in the blood pressure or to some change in the vessels. The rapidity of its appearance and disappearance makes it extremely improbable that there was any change in the vessels, and we are left with a variation of the blood pressure. The view that the last might be operative seems to be supported by the statement of Ranke, that the blood accumulates in the muscles of a healthy man during exertion, while it is diminished in the organs which are at rest."

Dr. Keen stated that in the case he reported, in the course of a year the albumen has become constant, though his exercise has been restricted to the last degree consistent with health; but the amount is never over a faint trace. At no time have any casts or blood been discovered. A prolonged sea voyage is now being tried as a means of cure.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, January 27, 1885.

The President, R. F. Weir, M.D., in the Chair.

REMOVAL OF THE UTERUS AND ITS ANNEXA BY ABDOMINAL SECTION; DEATH ON THE SIXTH DAY FROM PERITONITIS EXCITED BY THE PRESENCE OF A SPONGE.

Dr. Briddon presented a specimen accompanied with the following history: N., aged 27, came under my observation for the first time on the first day of

November, 1884, when I was furnished with the following history: She was delivered of her first and only child three years ago. She suffered on that occasion from post-partum hemorrhage, and was informed by her physician that she had a tumor. Eighteen months subsequently she began to suffer from menorrhagia and metrorrhagia, which conditions increased so much that on several occasions there was great difficulty in controlling the flow. In July, 1884, she began to suffer from pain associated with the discharge of large clots. In October, she became so much exhausted that she had to take to her bed, where I found her. She was a tolerably well-nourished, but much exsanguinated, woman. An examination of her lungs, heart, and urine had yielded negative results. Inspection detected nothing but a very moderate prominence in the hypogastric region. Palpation discovered a tumor in the median line, which had the configuration of the uterus, and which reached to about the level of the umbilicus. Auscultation could detect no pulsation of the fœtal heart. Examination by the vagina found the os patulous, the cervix shortened, and the finger came in contact with a tumor apparently projecting into the cavity of the uterus. Bimanual examination made out that the vagina was continuous with the tumor above the pubes. The diagnosis of submucous fibroma was made. It was advised to use hypodermic injections of ergotin three times a week until the local conditions were favorable for enucleation.

Nov. 20.—She had an attack of hemorrhage of a very alarming character, which only yielded to the liberal use of ergot and the tampon. The condition of acute anæmia that followed this was of a very serious character. Intense thirst, vomiting, restlessness, sighing respiration. At one time preparations were made for the intravenous use of salines. Nothing was retained but iced champagne, which was given continuously, and it was only by the most assiduous care of her attendants that she was tided over. Then it was determined, by the liberal use of such food and wine as she could assimilate, to prepare her for such operative procedure as might be necessary to prevent another hemorrhage.

Jan. 1, 1885.—Her condition appeared to warrant a more thorough examination. A large tupelo tent was introduced into the cervix, and in twenty-four hours she was etherized. A finger introduced into the cavity of the uterus detected a pretty large tumor, which was continuous with the wall of the cavity. When the hand was introduced into the vagina, two fingers could be passed through the cervix, and directly up to the left cornua; and when these two fingers distended the cavity of the uterus, no tumor could be felt within. But bimanual examination proved that the tumor occupied the right side of the uterus and the corresponding broad ligament, and it was determined to remove the tumor by the abdominal section as soon as her condition appeared to warrant it. She was put upon a nutritious diet, and a liberal use of Burgundy.

After the end of the first week in January, the patient's condition appeared to warrant the contemplated interference. She was prepared by the usual aperient and thorough personal disinfection. The room in which it was proposed to do the operation was properly prepared, instruments, with a single exception, were boiled, brushed, and soaked in carbolic acid solution. Sponges, round and flat, were prepared a week before. Hypodermic of morphia and atropia was administered at 2.30 January 10th, and the patient was placed under the influence of ether.

An incision was made in the median line from below the umbilicus to just above the pubes. After the arrest of hemorrhage from a few bleeding points, the peritoneum was opened and the tumor exposed. It was found to involve the right side of the uterus, passing into the corresponding ligament. There was also found a small cyst in the ligament, and unconnected with the uterine tumor, and a cyst as large as a lemon in the left ovary. The tumor was held down in the pelvis so firmly that it was found impossible to lift it out until after ligation and separation of the broad ligaments. This division was made well outside the tubes and ovaries. Even after this liberation, it was found difficult to bring the supravaginal portion of the cervix into the view. A stout cod line was then passed round the tumor, and tightened by an écraseur, so as to compress the cervix temporarily, preparatory to the application of an elastic ligature, which was passed twice round and clamped. The cod line was then removed, and the section of the tumor was absolutely bloodless. It was intended to transfix the pedicle above the ligature with some gilt steel acupressure needles, but they were not deemed sufficiently strong, and a trocar was used. This was the exception referred to in the statement that all the instruments had been scrupulously cleaned. The trocar was clean, and was in the carbolic solution, but it had not been as thoroughly treated as the others. There was nothing to clean out of the peritoneum save a little blood from stitch-holes, and that was absorbed by a flat sponge. The abdominal walls were brought together by silk sutures. There was some little difficulty in placing the stump outside of the walls. It was well dusted with iodoform, and twelve layers of fifty per cent. iodoform gauze were used in the dressing, supplemented by a quilt of bichloride jute.

The tumor weighed three pounds. It was of a soft, succulent character—so soft, indeed, as to convey the impression that it was fluctuant, probably of the myxomatous variety. A subsequent examination made out that it was a soft fibroma.

On the day following the operation, the condition of the patient was satisfactory. Her pulse was frequent, and her temperature was 103°, but her general appearance was good, She complained of some pain due to the traction of the stump. She was given opium in moderate doses in the form of enemata, and a refrigerating coil was applied to the abdomen. On the second day, her temperature was 102°. The vomiting had ceased. On the third day, the temperature was down to 101°, and everything seemed hopeful. On the fourth day, there was a very unfavorable change; her temperature went up to 104°. I made a very careful examination, and could find no cause. When I was informed of the change in her condition, I took a glass drainage-tube with me, supposing that there must be something confined within the cavity of the peritoneum that required an outlet. On removal of the dressing, there was absolutely no evidence of anything that would warrant interference. There was no abdominal distention and no tenderness, and I supposed the symptoms must be due to blood poisoning. She was given stimu-

lants, hypodermics of morphia, and the refrigeration was kept up. But it was all in vain; the temperature came down a degree, but the heart failed rapidly, and she died on the morning of the sixth day.

The following is the report of Dr. William Henry Porter, who made the autopsy twelve hours after death:

"The external abdominal wound was the only surface abnormality. The abdomen was opened by straight and elliptical incisions, so that the wound and attached stump were removed entire. The incision to the right of the wound bisected a small pocket of pus, which communicated with the operation wound by one of the stitch-holes.

"Thoracic cavity: Heart and lungs normal, excepting a little fatty change in the former.

"Abdominal cavity: No distention of abdomen or undue accumulation of gas in intestines. No general peritonitis. Spleen firm and dark in color. Kidneys: both glands larger than normal. They are anæmic. Capsules normal and non-adherent. Underlying renal surface smooth. Cut surface granular. Cortex thickened. Microscopic examination: The epithelial cells, both of the straight and convoluted tubules, showed the protoplasm to be in a state of fine granular metamorphosis. This had caused the cells to become swollen, and in many places the lumen was nearly closed by them. At other points, the cells were becoming detached, the intertubular tissue was swollen and œdematous. The lesion is that of an acute parenchymatous metamorphosis of the renal cells, one which develops during the last few days or hours of life, and is often found at the necropsy.

"When the intestines were detached from the mesentery, at a point thirteen feet below the stomach, a collection of pus was found located in the substance of the mesentery, and bound to the intestinal wall by fibroplastic inflammatory exudation. From this point down to the cæcum, the small intestine and a part of the colon were in the pelvic cavity, and more or less glued together by inflammatory exudation. The recto-vaginal pouch was covered by a layer of recent deposit and a very small amount of pus. The stumps left by excision of the ovaries were not inflamed. The inside of the wound bore evidence that the healing process was progressing favorably. One end of the elastic ligature, external to the clamp, protruded into the peritoneal cavity, possibly pulled through during evisceration.

"In the iliac fossa near the cæcum, a sponge was found, seven centimetres in diameter. It was almost, if not entirely, encapsuled by inflammatory lymph.

"The wound and stump being in such good condition, and the pelvic inflammation being most advanced on the right side, point toward the foreign body as the cause of inflammation.

"Liver, weight, sixty ounces. It was slightly fatty. A few points resembling fat emboli, or commencing pyæmic foci, were found. The hepatic cells showed fatty infiltration and degeneration; also bile pigmentation.

"The cause of death in this case may be ascribed to the original operation, peritonitis, and an overworked pair of kidneys."

The fatal flaw in the technique of this operation was the omission to count the sponges before closing the wound. I cannot plead ignorance of the necessity for attention to so important a detail, for I was conversant with the accidents from such cause published in the literature of the subject. How it could have happened, surrounded by my trustworthy friends, men accustomed to deal with such cases, is more than I can tell.

Dr. Sands had recently heard of an instance in which a few months ago ovariotomy was performed, and one or two days after the operation unpleasant symptoms developed. It was then found that a sponge was missing; the surgeon opened the abdominal cavity, removed the sponge, the unpleasant symptoms disappeared, and the patient recovered.

Dr. Markoe referred to a case in which the accident of leaving a sponge in the bottom of a wound occurred in his observation. It was one of deep sinus of the popliteal space, which for many months had been treated by a medical gentleman by the use of sponge-tents. Finally Dr. Markoe was called upon to operate. In order to facilitate following the track of the sinus, he injected the cavity with black ink, for the purpose of staining every part of the tract, and at the operation he followed out every part of the sinus with the greatest care. The late Dr. Van Buren assisted him at the operation. No disease of the bone was found. Subsequently the case did very well, but the sinus remained as obstinate as ever, and after a time the gentleman went to Philadelphia, where he consulted one of the leading surgeons in that city, who recommended an operation, and performed it, and its performance disclosed the presence of a piece of sponge as large as the smallest commonly used, which was lodged in the cavity, and was surrounded by dense fibro-plastic material. The foreign body was removed and the patient recovered. He had the satisfaction of dividing the responsibility with the gentleman who had previously used sponge-tents as to who had left the sponge in the wound.

Dr. Stimson said there was a practical lesson to be learned from Dr. Briddon's case, as the accident was plainly the result of using a handful of small sponges for the purpose of holding back the intestines, instead of one large flat sponge.

Dr. Briddon remarked that his directions always were to use the small sponges only during the operation of making the incision in the abdominal wall down to the peritoneum; then they should all be removed, and afterward the large flat sponge employed.

Dr. Hall asked if we were justified in assuming that an aseptic sponge left in the peritoneal cavity would cause peritonitis.

Dr. Gerster wished to add two cases, not on account of the fact that sponges remained in the wound, but because he was able to say that the sponges were not forgotten, but remained in spite of the wound being carefully explored for them. The sponges which he used were Florida sponges prepared after the method of Keller, which leaves some of them exceedingly brittle.

After having removed the breast of one patient, it was necessary to enter deeply the axillary cavity, and sponges were packed into the deepest portion of the cavity during one part of the operation, and there one of them became so matted together and united with the wound surface, that when the sponge was seized to be extracted, a portion of it, about the size of the last joint of one's thumb, separated and remained behind.

The surface of this fragment was so smooth from the blood-clot enclosing it, that it was not recognized by subsequent exploration of the wound with the finger. The external wound healed by first intention throughout. Everything seemed to be doing well, and at the expiration of ten days he withdrew the drainage-tube which had been placed through a counter-opening made in the latissimus dorsi muscle. A day or so afterward, suddenly, high fever set in, without any apparent reason, but soon the nature of the disturbance was disclosed, for a fluctuating swelling with redness of the skin developed in the axillary region, and a large quantity of pus was evacuated, when the piece of sponge was discovered and removed.

A similar instance occurred to him in a case of extirpation of the rectum, in which a portion of a sponge remained in the deepest part of the wound beyond the pelvic fascia. It resulted in the formation of abscesses in the prevertebral connective tissue, and the case terminated fatally by septicæmia.

The President remarked, that it seemed, in Dr. Gerster's first case, the sponge did no damage until it was exposed by the removal of the antiseptic dressing.

Dr. Gerster remarked that he would be rather inclined to believe that there were septic substances in the sponge which produced the trouble, although there was no suppuration before the dressings were removed. There was a case on record which he remembered to have read some years ago, reported by Volkmann, who once performed exsection of the hip-joint and left a sponge in the acetabulum, which remained for a long time, causing no trouble whatever, but finally trouble was developed, and it was removed by operation four or six weeks after the performance of the exsection.

Dr. Briddon referred to the fact that this accident had occurred in one of Tait's own cases, and that Tait referred to ten others in which it had occurred.

The President also remarked that a paper had recently been published in which twenty cases of the occurrence of this accident had been reported.

EPITHELIOMA OF THE PENIS.

Dr. Briddon presented a patient, a man forty years of age, who submitted to amputation of the penis by one of his colleagues in the Presbyterian Hospital, in August, 1884. The operation was performed a short distance behind the glans. In October following, the patient entered Dr. Briddon's service at the hospital, and on examination it was found that there was a return of the disease in the stump, with induration of some of the inguinal glands. Dr. Briddon amputated the penis according to the plan devised by Demarquay, by making two elliptical incisions, circumscribing the penis at the root, and terminating in the perineum just in front of the penis. The perineal portion of the spongy urethra was then dissected from the corpora cavernosa, turned down, and stitched to the margin of the perineal wound about one inch in front of the anus. The penis was then drawn forward, and dissected from the pubis by hugging the front of the bone closely with the knife, cutting off the crura from the ramus on either side. Dr. Briddon suggested that this step in the operation would be improved by hugging the crura of the penis with the knife as they join to form the covering of the body, and in that way a greater length of bloodvessels would be insured outside of the triangular ligament. The indurated inguinal glands were removed at the same operation. Union was retarded by faulty drainage. There was already evidence of return of the disease in the stitch-holes in the inguinal region, and possibly just above the scrotum, but whether the induration above the scrotum depended upon a return of the disease, or whether it was due to the induration surrounding the sinus, which existed for some time, he was not prepared to say, although it was probably due to the former. The patient experienced no difficulty in passing his urine, although he was obliged to take a sitting position when he emptied his bladder.

Dr. W. T. Bull referred to a case which he reported to the Society about one year ago, in which precisely the same operation had been performed, and although the inguinal glands were enlarged upon both sides, and were indurated, they disappeared altogether very soon after the operation. Already one year and a half had elapsed since the operation, and there had been no recurrence of the disease.

MEDICO-CHIRURGICAL SOCIETY OF MONTREAL.

Stated Meeting, February 6, 1885.

Prof. Thomas G. Roddick, M.D., in the Chair.

The Chairman related the following case of

SUBPERIOSTEAL AMPUTATION AT THE HIP-JOINT,

and exhibited the specimen.

I. McL., aged 35, five years ago received a severe injury of the hip-joint by falling through a trap-door and being suspended by his right foot, which caught as he fell. The joint, after the accident, was much swollen and very painful, and patient was confined to bed for a month. He then got about with some difficulty, the joint being still swollen and painful. During the next four years, he was sometimes better and sometimes worse, but never able to use the joint perfectly, as it was always stiff and somewhat painful. A year ago he consulted Dr. Roddick, who treated him by extension and rest, under which he rapidly improved, and was soon able to go home with his hip-joint fixed in an apparatus devised by Dr. Roddick. For several months, patient progressed favorably, and was entirely free from pain. The joint, however, again became painful, inflamed, and swollen, and an abscess opened in front of thigh to the inner side of Scarpa's triangle. He again came into town and saw Dr. Roddick, who made free incisions on the outer side of the thigh, draining the abscess as thoroughly as possible. The patient did not improve, but had nightly elevation of temperature with profuse suppuration. The joint was now quite rough on manipulation, and apparently entirely disorganized. It was found impossible to drain the abscess cavity thoroughly, and the pus began to burrow deeply along the muscles. The patient's temperature kept continuously high (103–4°), and he had one severe rigor. His general condition was unfavorable. He now consented to operative procedures. Dr. Roddick decided to perform excision if possible, and if not, to proceed to amputate at the hip after the method of Furneux Jordan.

He was placed under ether on February 3, 1885, and an exploratory incision made on the outside of the thigh over the trochanter major. It was now found that not only the head of the thigh-bone and acetabulum were diseased, but the upper third of the bone was bare and necrosed, and that pus had burrowed in all directions. It was thought that excision would be of no benefit, owing to the great extent of the disease and the condition of the patient; so it was determined to amputate at the hip-joint. An Esmarch bandage having been applied high up, the thigh was amputated by the circular method at the junction of the middle with the upper third, and then, after the vessels had been secured, the upper end of the femur in the stump dissected out by an incision on the outer side, as recommended by Mr. Furneux Jordan. By this operation the vessels were divided low down and secured without difficulty and with almost no loss of blood. After resecting the femur, several large pieces of necrosed bone were removed from the acetabulum.

Notwithstanding the little loss of blood, the shock was very severe, and, although the patient rallied slightly after the operation, he sank within twenty-four hours in spite of all treatment. Dr. Roddick said that, in addition to performing Jordan's operation, he peeled off all the periosteum from the upper part of the thigh-bone before removing it. The specimen which was exhibited to the Society showed almost complete absorption of the head of the femur, with necrosis of the upper part of the bone. Several large sequestra which had been removed from the acetabulum were also shown.

TUMOR OF THE BLADDER.[1]

DR. RODDICK stated that the case of removal of a large tumor of the bladder some three months ago, and which he had reported to the Society, had lately died. The man was doing well, and the wound had almost closed, when his health began to fail, and pus appeared in large quantities in his urine. Then a large scrotal abscess formed, and weakened him a great deal, and he gradually sank and died from exhaustion. The bladder, kidneys, and ureters were shown. The point of attachment of the tumor was seen a little to the left of the neck, and at the point where the pedicle had been attached was seen a small nodule healed over. The bladder itself was hypertrophied, and exhibited all appearances of obstructive disease. The ureters were much dilated, and both the kidneys were affected with suppurative interstitial nephritis.

CANCER OF PYLORIC END OF STOMACH AND PANCREAS.

PROF. GEORGE ROSS reported a case of malignant disease of the pyloric end of the stomach with secondary disease of the pancreas, and exhibited the specimens. The history of the case was as follows:

Dr. Ross saw the patient, a man, aged 40, a year ago. At that time he complained of dyspeptic symptoms, such as acidity, flatulence, etc., and failing health. He improved under treatment; but when seen some months later, he complained of vomiting at intervals of considerable length—one, two, and three days. Vomiting was preceded by great uneasiness, and a sense of distention. The vomiting, as a rule, was a voluntary effort, and gave great relief. On examination, the patient now presented all the symptoms of a dilated stomach, and the diagnosis was disease of the pyloric end, with dilatation of the stomach. No tumor could be felt, nor was there any pain. Some time after, he entered the hospital to be treated by siphon and douche, and then no dilatation could be made out, and the vomiting had almost entirely ceased; very occasionally, however, he vomited frothy matter which contained abundance of sarcinæ ventriculi. During the summer he improved somewhat, and was able to get about. In the autumn his health began to fail rapidly, but there was no pain or vomiting. In October last, he began to exhibit a slight yellowish tinge of skin; the color deepened gradually, and emaciation steadily increased. A month later, an indistinct fulness was felt about the pylorus, but this could not be accurately defined. Diagnosis was malignant disease of the pylorus, with pressure on the bile-duct. He gradually became weaker, and died of exhaustion a month ago. Throughout the whole course of his illness, he never suffered in the slighest degree from pain. At the autopsy, the stomach was found but slightly dilated, the pylorus was found to be the subject of malignant disease, and the pyloric orifice was much contracted, and admitted with difficulty an ordinary lead-pencil. There was also secondary disease of the head of the pancreas, with almost complete obliteration of the common bile-duct.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, Thursday, February 5, 1885.

THE PRESIDENT, B. F. BAER, M.D., IN THE CHAIR.

CERVICAL PREGNANCY.

DR. E. E. MONTGOMERY read a paper in which he recounted the history of a case seen by him in consultation with Dr. Alexander. The patient had been pregnant eight times; the last labor had been terminated by forceps. The present pregnancy had lasted three months, when she was taken with severe pain and quite profuse hemorrhage. An examination under ether disclosed that the cervix was distended, forming a globular tumor. The os, turned backward, was filled up with a tense membrane; breaking through it, the cervix was found to be a large cavity, in which was the fœtus and its envelopes. The body of the uterus appeared like an excrescence upon the distended cervix; it would admit a finger, and was lined by a decidua. The membrane below was continuous with the outer mucous membrane of the cervix, so that the remains of it hung as a fringe from the os.

This case differed from the few cases of this condition described, in that there was no contraction of the os; in the majority of cases it occurs in primiparæ, and when discovered it was necessary to proceed to artificial measures to make an opening.

DR. GOODELL remarked that he had no knowledge of cervical pregnancy. One case which had been sent to him as such was epithelial cancer of the cervix. How could such a case be diagnosticated without a post-mortem examination? Dr. Montgomery's hypothesis of an arrested abortion is probably the correct solution of such a case as he has described. The fœtus might be forced out of the body of the uterus and arrested in the cervix by an unyielding os, or by cica-

tricial bands. Some years ago, a physician of this city who had a large obstetrical practice, borrowed Dr. Goodell's écraseur for the removal of a supposed uterine polypus, which proved to be a fœtus in its amniotic sac. Dr. Goodell had never been able to understand how an experienced man could make such a mistake, but the description of this case of cervical pregnancy has thrown light upon the matter. Dr. Montgomery's description of the distended cervix would apply very well to uterine polypus with a long pedicle, and a mistake in diagnosis might easily be made.

DR. MONTGOMERY questions the primary occurrence of cervical pregnancy. He believes the fœtus has originally taken its seat in the body of the uterus, and has been forced into its lower position later; but it might be primary, the internal os being patulous, the same conditions that sometimes cause placenta prævia might cause the entire fecundated ovum to be arrested in the cervix.

RUPTURED UTERUS.

D. B. F. BAER presented the specimens and related the history. Mrs. F., colored, 32 years of age, married ten years, had borne four children at term, and had one miscarriage. The first child was forceps-delivered, and was still-born. November 14, 1884, she was taken in labor. A midwife was in attendance, who pronounced everything correct. After a few hours of severe pains, the patient "felt something break in the womb," and labor ceased, but was replaced with sharp pains all over the abdomen; blood escaped in great quantity from the vagina. Collapse ensued, and she was thought to be dead; a slow reaction occurred, and her attendants waited for labor to begin again. Dr. Fisher was called to see her ten days after the accident. He found her abdomen tender and tympanitic. a mass like the head of a fœtus in the right hypochondriac region. The pelvis was empty. Temperature 103°; pulse 108, and small. Rupture of the uterus, and escape of the fœtus into the abdominal cavity was diagnosticated. Dr. Baer was called in and confirmed the diagnosis. The patient refused operative assistance, and preferred to die in peace, but five days later asked to be relieved. Preparations were made for laparotomy. An examination per vaginam revealed gangrenous pus escaping freely, and the placenta loose and hanging from the vagina. The hand passed readily through the os uteri and through a tear in the right wall of the cervix into the abdominal cavity and came upon the trunk of the child. The latter was extracted through the vagina by version by the feet; it was putrid. The parts were all irrigated with carbolized water, and the hand again introduced entered an adventitious sac and nowhere came in contact with intestines or other viscera. The uterus was well contracted and quite small. The uterus and sac were washed out with carbolized water until it returned pure. The patient died of septicæmia ten days after the removal of the fœtus. Dr. Baer is in full accord with the principles advanced by Dr. R. P. Harris in his paper entitled, "If a woman has ruptured her uterus during labor, what shall be done to save her life?" (*Amer. Journ. Obstet.*, October, 1880, p. 809), in which he advises that the abdomen should be opened and the peritoneal cavity thoroughly cleaned. In this case, however, nature had protected herself by forming an adventitious cavity, and there could be no reason to open the abdomen to clean this out, as it could be reached from below more directly and without injury to the soft parts.

DR. HENRY M. FISHER said that in Germany a distinction is made between lymphatic septicæmia and phlebitic septicæmia. In the first form the poison is absorbed by the lymphatics and inflammation of serous surfaces with exudation is the consequence. In the phlebitic form, numerous emboli are formed and hectic fever and local pus formations, the result of these emboli, are found. At the autopsy, in this case, pleural and pericardial effusion was found. It will be remembered that peritonitis occurred very soon after the rupture.

DR. GOODELL remarked that he had come intending to criticise Dr. Baer's treatment of this case for not resorting to laparotomy. But he found himself agreeing with both Dr. Harris and Dr. Baer. In recent cases laparotomy should always be performed, but in fifteen days an adventitious sac had been formed, and the dangers to the patient would have been increased by operation. He had seen two cases of rupture of the uterus, both of them occurred in the practice of a physician who never used obstetric forceps and had to send four miles for a consultant. In the first case peritonitis rapidly supervened, the abdomen became very much enlarged and the fœtus could not be located by palpation. The abdomen was not opened. After long groping the fœtus was found close under the diaphragm. He had great difficulty in extracting it, as the loops of intestines became entangled between its legs: the placenta was also found in the abdomen. In the other case, the body of the fœtus had escaped into the abdomen, but the head was still in the uterine cavity; it was delivered by forceps. Both patients died. In both cases it would have been far better to have opened the abdomen. *Amer. Journ. Obst.*, vol. x. p. 478, 1877.

DR. HARRIS was in accord with Drs. Goodell and Baer as to the proper treatment of the case reported. It was too late to do anything when the physician was called. The general opinion is coming around to coincide with his way of thinking concerning the propriety of laparotomy in all cases as soon as reaction from the shock of rupture and hemorrhage has been established. Of the cases reported, after such treatment, 50 per cent. have recovered. One woman has been reported as having ruptured her uterus in four successive labors with delivery per vaginam and without laparotomy, and she survived it all, but such a case is phenomenal. Three cases in Europe have been treated by removal of the uterus as in the Porro operation; they all died; there seemed to be no reason for such a method. In most cases the split extends through the cervix, and thus free drainage from the abdominal cavity is secured. One reason for closing the cervical rent by sutures is to avoid the danger of cancerous growths to which that lesion is supposed to give rise.

DR. LONGAKER remarked that many of these cases died from the profound shock and hemorrhage immediately following the accident. Two cases in his experience had died within two hours, one of them undelivered.

DR. BAER was glad to hear Dr. Harris make the distinction as to the propriety of laparotomy in his case,

where the patient was not seen until fifteen days after the accident, and was suffering from septicæmia. He had intended to perform laparotomy and was prepared for it, but when he found the newly developed sac he changed his plan, as he thought nothing could be gained by it.

NEWS ITEMS.

MONTREAL.

(*From our Special Correspondent.*)

Preparations Against an Invasion of Cholera.—A special meeting of the Montreal Medico-Chirurgical Society was held February 13, 1885, to discuss the means necessary to prevent the importation and spread of contagious diseases, especially cholera. There were present at the meeting representatives of the Board of Health, School Commissioners, and members of the French Medical Society. Dr. Larocque, the Health Officer, opened the discussion with a short paper.

A new health bill was advocated similar to that which at present exists in Ontario. It was also suggested that district physicians be appointed, and that all contagious diseases be reported to the Board of Health.

The abolition of yard privy vaults was recommended, as it was said there were 10,000 in the city, of which only 1500 were yearly emptied. It was also suggested that night soil should be burnt. More sanitary police were needed to carry out sytematic inspection of houses and premises in order that the city should be properly cleansed before summer in order to be prepared for cholera. The sewers were advised to be flushed at intervals; and, in conclusion, a more efficient ambulance service was demanded.

The Army Medical Library and Museum Building.—A bill appropriating $200,000 for the erection of a fire-proof building for the accommodation of the valuable collections of the Army Medical Museum and Library passed the House last Monday. This action insures the final passage of a bill at this Session which will enable the building to be completed by the time of meeting of the International Medical Congress, in 1887.

The Southern Branch of the New York State Medical Association will hold a meeting in Brooklyn on Wednesday, February 25th, at which several valuable papers are promised.

Gaillard's Medical Journal.—We are informed that this periodical will pass under the editorial management of Dr. P. Brynberg Porter, of New York.

The Cholera and the Illinois State Board of Health.—At an adjourned meeting of the Illinois State Board of Health, held February 7th, the following preamble and resolutions were adopted:

Whereas, The season is fast approaching when, it is feared, Asiatic cholera will again assume epidemic proportions in Europe and so threaten this country with a national calamity; and

Whereas, In the judgment of this Board such calamity may be averted by a system of preventive measures based upon the requirements of modern sanitary science;

Therefore be it resolved, That this Board respectfully, but urgently, requests: First, That the President of the United States convene the National Board of Health forthwith, and put at its disposal, subject to his approval, the unexpended balance of the appropriation made at the last session of Congress for a contingent epidemic fund. Second, That the Illinois Senators and Members of Congress push the prompt appropriation of the sums recommended by the House Committee on Public Health. Third, That authority be, by a joint resolution of Congress, conferred upon the President to issue a proclamation forbidding immigration from infected countries whenever, in the judgment of the National Board of Health, such immigration threatens the public health of this country.

Second Report of the Special Cholera Commission in India.—The supplement to the official *Gazette of India* contains the following memorandum from Surgeon-General J. M. Cunningham, M.D., Sanitary Commissioner with the Government of India:

In continuation of my letter of the 27th ult., I have the honor to submit, for the information of the Government, the accompanying communication from Dr. Klein, and to suggest that it also may be published in the supplement to the *Gazette of India* for general information.

The fact that comma-bacilli have been found in tanks without any case of cholera having occurred among the large number of people using them, is an observation of much interest and importance in regard to the relation of comma-bacilli to cholera. The observation has a special interest and importance, moreover, from the circumstance that one of the tanks in question is the *same tank* as that in which Dr. Koch found comma-bacilli, and so hastily concluded that the outbreak of cholera which took place about that time among persons using this tank had been caused by the comma-bacilli it contained.

Dr. E. Klein appends a report in which he refers to the situation of the bustees, and the general use made of the tanks near by for all purposes—cesspools, washing of clothes, utensils, and drinking. The fact that comma-bacilli were found in the water of a certain tank, and that only one case of cholera occurred within a month, though the water was in general use, is referred to as specially significant as relating to the question of the etiology of the disease.—*Lancet*, Jan. 31, 1885.

Sir Joseph Lister.—The Emperor of Germany has just conferred on Sir Joseph Lister the "Ordre pour le Mérite" for Science and Arts. This act of the venerable Emperor is a generous recognition of the claims of British medical science. In commenting on it, the *Lancet* says: "The discoverer of vaccination has been more honored in Germany than in his own country, in accordance with the Scripture that 'cannot be broken.' The quiet revolution in surgery, involving the practical abolition of pyæmia, hospital erysipelas, and gangrene,

and an infinite diminution in the calamities of surgery, which we owe to Sir Joseph Lister, more than to any other single man, is a service to mankind not quite on the same scale as the discovery of vaccination, but of very far-reaching consequence."

THE CHAIR OF PATHOLOGY AT LEIPSIC.—PROF. BIRCH-HIRSCHFELD, of Dresden, has been nominated to the Chair of Pathological Anatomy at Leipsic, vacant by the death of the late Prof. Cohnheim. The new professor is perhaps best known for his exhaustive text-book on Pathological Anatomy, of which the second edition is now appearing. He has done much original work in bacteriological subjects. He is not, therefore, likely to pursue the physiological line of inquiry so much advanced by the late illustrious teacher.—*Lancet*, Jan. 31, 1885.

SCIENCE AT TURIN.—It has been determined to spend the very liberal sum of £120,000 in creating new scientific buildings in connection with the University of Turin. Half that sum will be provided by the Provincial and Communal Councils of the City, and the other half by the Government, with the sanction of the Italian Parliament.—*Lancet*, Jan. 31, 1885.

NOTES AND QUERIES.

CASE OF CONGENITAL AND HEREDITARY ABSENCE OF LEFT BREAST.

To the Editor of THE MEDICAL NEWS.

SIR: On the 8th of August, 1883, I delivered Florence C. of a healthy male child. During the labor, which was complicated by convulsions, the patient happening to throw her left arm over her head, I noticed that the skin in the axilla was perfectly bare and smooth, and on looking further, was surprised to find that there was an entire absence of the left breast, there being only the rudimentary nipple, as in the adult male. The right breast was perfectly developed, and there was already some secretion of milk in it. On questioning the girl a few days afterwards, she stated that her mother, who is still living, has only one breast—the right one—and that she had given birth to eight children, and had nursed and raised all of them. The grandmother had the same peculiarity. Florence is a pronounced brunette, with long black hair on scalp, and abundance of hair in right axilla and on mons veneris. She has nursed her child uninterruptedly, and it is now healthy and well developed.

CHARLES W. BADEAU, M.D.

ALLENDALE, NEW JERSEY.

PHOSPHATE OF SODA IN HEPATIC COLIC.

To the Editor of THE MEDICAL NEWS.

SIR: Apropos to the recent discussion in the New York Surgical Society, as published in your issue of January 31st, you are at liberty to publish the following notes of a case occurring in the rural districts:

Mrs. J., aged 28, was seen on the 22d of October, 1884. Found her suffering intensely, the pain being referred to the region of the gall-bladder. The patient herself was firmly of opinion that she was suffering from gall-stone, and said her sister had suffered in the same way, discharging the stones a few days after the attack. This patient further said that she had suffered with similar attacks at intervals for ten years. On the 23d of October, having relieved the suffering of the day before by morphia hypodermically, I put her upon drachm doses of the phosphate of soda three times a day. To quote her own expression, "the region of the liver felt as if it were being ground up." On the 25th, two days after, over one hundred gall-stones, varying in size from a duckshot to a large pea, were discharged per rectum. The present health of the woman is excellent, and she has had no further trouble. The phosphate of soda was continued for several weeks, but has been dispensed with now for two months. What one of the laboratory staff of the profession will give us, the *rationale* of the action of this remedy in this class of cases, and also in catarrhal jaundice, for which it sometimes seems to act as a specific?

J. B. BRISTOW, M.D.

FARMINGTON, TEXAS, Feb. 14, 1885.

DIAGNOSTIC SIGN OF PREGNANCY IN THE FIRST MONTH.

To the Editor of THE MEDICAL NEWS.

SIR: In your issue of February 7, under the heading of "A New and Certain Diagnostic Sign of Pregnancy in the First Month," you attribute the discovery to Reinl, the date of the announcement as 1884.

The writer has frequently heard Prof. Goodell refer to it in his clinic at the University, and I would respectfully call your attention to his announcement of the fact on p. 26 in *Goodell's Lessons in Gynecology*, Philadelphia, 1880. He says: "A good off-hand rule to remember (in the introduction of the uterine sound) is this: 'When the cervix is as soft as one's lips, the woman is probably pregnant. When it is as hard as the tip of one's nose, the womb is most likely empty.'" Very respectfully yours.

W. G. HOWELL, JR.

GERMANTOWN, Feb. 16, 1885.

AGAINST A STATE BOARD OF MEDICAL EXAMINERS.

At the regular monthly meeting of the Montour County (Pa.) Medical Society, held January 22, 1885, the following resolutions were unanimously adopted:

Resolved, That we consider the proposed Legislative Enactment, establishing a State Board of Medical Examiners and Licencers, in its logic, expediency, and practicability, a crab-like effort at advancement.

Resolved, That the recognition of and coöperation with an irregular school of medicine, as provided in the measure of said Act, violate the letter and spirit of the State and National Codes of Ethics, and foster and perpetuate a delusion that is justly doomed to early extinction.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 10 TO FEBRUARY 16, 1885.

ROBINSON, S. Q., *Captain and Assistant Surgeon.*—From Portland, Oregon, to his proper station, Fort Spokane, Wyoming Territory.—*S. O. 20, Department of Colorado*, Feb. 2, 1885.

KEAN, J. R., *First Lieutenant and Assistant Surgeon* (recently appointed).—Assigned to duty at Fort Sill, Indian Territory.—*S. O. 23, Department of Missouri*, Feb. 11, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING FEBRUARY 14, 1885.

GUITÉRAS, JOHN, *Passed Assistant Surgeon.*—When relieved at Key West, Florida, to proceed to Charleston, S. C., and assume charge, Feb. 11, 1885.

KALLOCH, P. C., *Assistant Surgeon.*—To report to Passed Assistant Surgeon Peckham, at Wilmington, N. C., for examination for promotion, Feb. 10, 1885.

GLENNAN, A. H., *Assistant Surgeon.*—Relieved from duty at New Orleans, La., to proceed to Key West, Florida, and assume charge, Feb. 11, 1885.

THE MEDICAL NEWS *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

ORIGINAL LECTURES.

THE TREATMENT OF WHOOPING-COUGH.

A Clinical Lecture delivered at the Philadelphia Hospital, December 3, 1884.

BY JOHN M. KEATING, M.D.,

VISITING OBSTETRICIAN AND LECTURER ON THE DISEASES OF WOMEN AND CHILDREN.

(Reported by William H. Morrison, M.D.)

GENTLEMEN: I shall to-day say a few words in reference to the treatment of whooping-cough. Special attention has been attracted to the therapeutics of this disease since the discovery by Burger of a peculiar granular matter in the sputum of whooping-cough, which has been termed the bacillus pertussis. This announcement has excited renewed interest in the treatment of this affection, for, if it be proven, it will alter almost completely the ordinary treatment of this disorder.

Dr. Jenkins, the resident physician, has prepared for your inspection some slides which are now under the microscope. The sputum was placed on the glass and dried over the flame of a Bunsen burner in order to coagulate the albumen. It was then stained with methyl-violet, thoroughly washed, and mounted.

You will note the irregular biscuit-shaped corpuscular bodies. These are supposed to be the cause of the disease, but as yet they have not been successfully inoculated.

It is hardly necessary to enter into a detailed account of the history of whooping-cough. Suffice it to say that it has three stages: the first being that of an ordinary catarrh. In the second stage there is abundant secretion of mucus which is freer than in any other affection. This interferes greatly with respiration, and has much to do in exciting the cough. In the third stage drying takes place, and the paroxysms diminish in number, but not in intensity. Finally the nervous element alone remains, and this gradually dies away. When not interfered with by treatment, it lasts about three months. Among the Japanese, the name applied to this affection signifies "the hundred days cough." At the present time there are methods of treatment by which its course can be materially shortened.

Whooping-cough is subject to many serious complications, especially complications resulting from the extension of the inflammation downwards into the air-passages. It is nearly always accompanied with bronchitis, which may result in pneumonia of the catarrhal variety. There is another serious complication which is due to the excessive expiratory efforts in coughing with obstruction of the larynx from mucus, and this is an emphysematous condition of the lung. If forcible expiration occurs while the larynx is occluded, dilatation of the air-cells necessarily takes place, and if this distention is repeated, rupture of the partitions of the air vesicles occurs, and emphysema results. The older the child, the less is the danger of permanent trouble. In addition to these there are certain cerebral complications which are liable to occur. There is intense venous congestion and even rupture of capillaries with effusion of blood. Clotting sometimes takes place in the cerebral sinus and jugular veins.

If whooping-cough be analyzed, it is found to present two elements: one is the catarrhal element, which, of course, affects the mucous membrane; the other is the nervous element and is very distinct, and it is this that gives rise to the paroxysms. These paroxysms, like the attacks of epilepsy, tend to their own cure. During the paroxysm the blood is almost entirely on the venous side of the circulation, and the anæsthetic effect of the carbonized blood on the cerebral centres relieves the attack.

The latest authorities believe that whooping-cough is a specific disease due to the presence of a microscopic parasite, entering by means of the mucous membrane of the air-passages. Some of the facts pointing in this direction are that it is one of the most contagious diseases of childhood; it runs a definite course, it occurs at all times of life, but one attack almost certainly protects from another. Why this is the case we are no more able to explain than we are in the case of the exanthemata, to which class it seems to belong. It is supposed by some that pertussis has a hardening effect on the mucous membrane of the larynx, which prevents the microbes of the disease from being absorbed. Whether the microscopical germs which have been described are or are not the cause of whooping-cough, is a question to be decided in the future. We know that the affection is due to something which can be carried from one to another. The question whether the symptoms of whooping-cough are due to the action of this peculiar material on the surface of the larynx, or whether it has first to be absorbed and exert its influence through the nervous centres cannot be positively answered. Personally, I am of the opinion that the poison may first get on the mucous membrane of the larynx, be taken up, and act on the cerebral centres. I believe this from several cases which have been reported, one of which was seen by myself, in which whooping-cough has been contracted *in utero*. Nevertheless, careful examinations of the blood, which have been especially conducted by Dolan, who has written an extremely interesting monograph upon this subject, have failed to reveal anything looking like the germ.

The child which I have brought before you to-day affords a marked example of this disease. Yesterday, he had twenty-four severe paroxysms. I call your attention to the condition of the eyes, which show the effect of the marked strain. The eyes are watery, the surrounding cellular tissue infiltrated, and they have a dark ring about them. This is one of the characteristics of whooping-cough. Where it is as marked as in the present instance, the diagnosis can almost be made

from it alone. There are other points in the appearance of those with whooping-cough which are often referred to. One of these is the ulcer under the tongue. The presence of this ulcer has been denied at times while at other times its presence has been acknowledged. The ulcer appears under the tongue on either side of the frænum, and is usually found at the height of the attack. It is due to the forcible expulsion of the tongue which comes in contact with the lower incisors. It is, however, said to have been found in cases in which the teeth have not protruded. The examinations made in this house show that the ulcer is sometimes present and sometimes absent. Where it is found, its presence constitutes a valuable evidence of whooping-cough, but if absent, the idea of whooping-cough is not excluded. At one time the presence of sugar in the urine was considered almost conclusive evidence of the presence of whooping-cough. It was supposed to be due to irritation of the respiratory centre, which we know will produce glycosuria. Examination of the urine of children suffering with whooping-cough reveals the presence of sugar in but few of the cases.

The only real evidences of whooping-cough are the history of exposure to contagion and the presence of the whoop, although this latter is not necessary, for whooping-cough may exist with simply a violent spasmodic cough, but present no characteristic whoop.

As regards treatment, let me say, in the first place, that if let alone, mild whooping-cough usually ends in recovery, unless one of the complications supervene. Previous to the last five or six years, the treatment has consisted almost entirely in the use of antispasmodics. It was considered that the disease chiefly affected the nervous system, and therefore such remedies as asafœtida and belladonna were employed, associated with external counter-irritation. Recent investigations have shown, as I have already stated, the presence of the supposed whooping-cough germ, and this has led to the treatment with antiseptics which has proved so efficacious that I propose to speak of it.

It has long been the custom to send children suffering with whooping-cough to the vicinity of gas-works, and this has been of service. The relief can probably be attributed to the presence of tar; the use of carbolic acid now does this.

We shall begin the study of the treatment of this affection by considering the influence of oxygen. In Germany, the inhalation of oxygen has been recommended especially by Niemeyer, and is said to be valuable. Here we use oxygen in the form of fresh air. Strange to say, that although fresh air is considered so beneficial in this disease, I find, in looking over the mortality tables, that the death-rate in the Southern States is as great, if not greater, than it is in the Northern States. This is probably due to the fact that the large mortality occurs in rickety and cachectic children, and that the children are often exposed to inclement weather, inducing complications. At the same time, the good effect of the soft balmy air of the sea, air saturated with moisture and the chlorides, is undoubted. The paroxysms are diminished in number and intensity, and the complications are warded off.

The next agent to which I shall refer is the steam spray. In some hospitals an attachment is made to the steam heaters, so that a room can be filled with steam. In private practice, steam may be obtained by slaking lime in the apartment, or, more conveniently, by the use of the steam atomizer. If the child remains in the city, he should have the range of several rooms well ventilated and kept at a uniform temperature. The air should be moistened with steam from a kettle on the stove (and each room should have this heat). The atomizer is also useful for the application of medicated solutions to the larynx. There are several of these solutions which may be employed. Carbolic acid is an extremely valuable one. The good effect of the carbolic acid is probably due to the direct action of the remedy on the mucous membrane of the larynx. It is an analgesic and is also supposed to act on the germ of the disease. The probability is that the local anæsthetic effect is the one which is obtained. Dobell's solution is perhaps the best means of applying this drug. It may be prepared according to the following formula:

℞.—Acidi carbolici (cryst.),	. . .	grs. iij.
Sodii biboratis,		
Sodii bicarb.,	. . . .	āā grs. xx.
Glycerinæ,	. . . . .	℥j.
Aquæ,	. . . . .	℥v.—Solve.

This can be used with the spray, and diminishes the tenacity of the mucus, favors its expulsion, and exerts a beneficial action on the paroxysms.

Another remedy which has been used with good effect in this way is the oil of eucalyptus, or eucalyptol. Quinine may also be used in the same way, but its bitter taste renders it objectionable for use with the spray, and it is better given in syrup or in the form of a powder. Thymol is certainly a valuable agent in this affection. It is, as is well known, a powerful antiseptic, second only to corrosive sublimate, and is supposed to act directly on the germs. The following prescription can be used with the atomizer:

℞.—Thymol,	. . . . .	grs. xv.
Alcoholis,	. . . . .	℥iij.
Glycerinæ,	. . . . .	℥ss.
Aquæ,	. . . . .	℥xxxiv.—Solve.

Corrosive sublimate, which is now used for almost everything, has also been applied here in the form of the spray. This is a dangerous drug to put into the hands of an unexperienced person, and as we have so many other useful remedies for this affection, I think it wise to avoid the use of corrosive sublimate. Listerine I have used extensively with good results in the treatment of whooping-cough. I employ it in the strength of one drachm to two ounces of water, with an ordinary hand atomizer. I direct the nurse to apply it a dozen or more times a day, and I find that little children, even babies, do not object to it. To it I add tincture of belladonna, potassium carbonate, or ammonium bromide, as the case may demand. The muriate of ammonia is also of great service in the form of the spray. Probably if it were not for the great expense of the drug, the hydrochlorate of cocaine would be valuable in these cases. I have used a spray of the fluid extract of coca with, I think, good results.

When the paroxysms of whooping-cough become very violent, the inhalation of a few drops of ether or chloroform is to be recommended. A few drops of

chloroform may be placed on the hand or on a handkerchief, and the child allowed to inhale it. It is safer to use ether, which is equally efficient. If at the same time the child is turned on its stomach, the mucus will escape by the mouth and the paroxysm will be relieved.

I shall next speak of the use of emetics. The severe paroxysms of this affection are usually brought about by the accumulation of thick, tenacious mucus in the larynx, and emetics act by bringing this away. The emetics ordinarily used in this affection are ipecac, alum, and the sulphate of copper, the latter being recommended very highly by Trousseau. Alum is probably the best. It acts in several ways. In the first place, it produces emesis with the expulsion of the mucus in the throat. It also acts directly on the mucus, coagulating it into small pieces, and facilitates its expulsion. This is considered as valuable as its emetic effect. If it is desired to produce vomiting, it should be given in doses of a fourth or half a teaspoonful, with syrup or honey, and this should be repeated until emesis is produced. The action of the emetic should be facilitated by placing the child on its stomach, with the head lowered, so as to invite the arterial flow to the head and relieve the paroxysm.

We next have to speak of the use of those sedatives which act primarily on the nervous system. It is stated by certain authorities that the disease can be cut short by such remedies as belladonna, bromide of potassium, and sulphate of quinia. I would place belladonna first of all. This has been used for a long time in the treatment of whooping-cough. It must be borne in mind while using this drug that children stand a proportionately larger dose than adults. It has usually been given in the form of the tincture of belladonna, but recently it has been recommended to use the sulphate of atropia in small doses frequently repeated. Belladonna has two effects. It relieves the spasmodic cough, and acts on the mucous membrane of the larynx, drying its surface. It has also been recommended to give atropia by hypodermic injection. The beginning dose of atropia should be the $\frac{1}{200}$th of a grain, and increased until dilatation of the pupil is produced, watching carefully the effects.

After belladonna come the bromides, which are quite useful. These also act in two ways. They exert a local effect on the mucous membrane of the larynx, and also have a sedative action on the nervous system. The bromides of ammonium, of potassium, and of sodium are those most frequently used. The bromide of ammonium acts more directly on the mucous membrane of the larynx as an analgesic, and it is said to act more efficiently when given by inhalation. The bromide of potassium has more of an antispasmodic effect. They can be used together.

Chloral is also very valuable in these cases, and it may be given at night in order to enable the child to rest, or it may be given in a smaller dose several times a day. For a child one year old, the dose would be two grains at bedtime, or one grain repeated three times a day. In my hands this has proven itself a most valuable remedy. Some are afraid to use it on account of its supposed depressing action on the heart. In children, by giving a smaller dose, a good effect can be obtained without danger. My own opinion is, that it is only in old cases, in which the heart has suffered strain, that any dangerous effects need be apprehended from this remedy.

Hydrobromic acid has also been found of service, for it acts like the bromides, and has the effect of drying up secretion. It is frequently used for this purpose in old cases of chronic bronchitis and bronchorrhœa. The dilute hydrobromic acid may be given in ten or fifteen drop doses every two or three hours. Or it may be given in one large dose at bedtime to enable the child to rest. Minute doses of morphia have also been used to relieve the paroxysms, but this I rather object to.

Some time ago, Binz, of Bonn, came out in an article, which was afterward endorsed by Dawson, of New York, recommending quinia most highly in the treatment of whooping-cough. The results of our experiments in this house have shown the efficiency of this drug in many cases. It has been found by experiment that the quinine must come directly in contact with the mucous membrane of the larynx. It has been applied by means of a powder containing the muriate or sulphate of quinia with bicarbonate of sodium and powdered acacia, which is blown into the larynx through a quill. My own plan is to give it suspended in the syrup of yerba santa, which is one of the best vehicles for disguising the taste of quinine. It is necessary to use a less soluble salt of quinine; for if the bisulphate is employed, an extremely bitter mixture will be the result.

The following formula may be used:

℞.—Quiniæ sulph., ... grs. viij.
Syr. yerbæ santæ,
Aquæ, ... āā ℥ss.
Sig.—One drachm represents one grain.

When given for this disease, the quinine must be pushed to large doses, giving it frequently during the day.

In addition to administering drugs to act directly on the throat, large doses of alkali, as the carbonate of potassium, may be given, with the object of liquefying the mucus and promoting expectoration. Where the amount of mucus is excessive, the bronchial tubes choked up, and the child has great difficulty of breathing, especially if there is a little fever and auscultation reveals all sorts of râles throughout the chest, it has been recommended that small doses of tartar emetic should be given. One-fourth of a grain of tartar emetic may be dissolved in four ounces of water, and a teaspoonful given every hour until the difficulty is relieved. It is often astonishing how soon this will afford relief. A few drops of compound syrup of squills which contains tartar emetic may also be given with the same object.

Astringents have also been found to be of service in this disease. For this purpose, alum may be employed, which not only has the effect already mentioned, but also acts as an astringent. Watson, many years ago, recommended that the throat should be painted with a solution of nitrate of silver, but the application is difficult.

Murrel, of London, has used drosera rotundifolia. A few drops of the tincture are put in a glass of water, and used during the day.

Albrecht has used muriate of pilocarpine, which promotes free expectoration and diminishes the tenacity of the mucus.

Benzoate of sodium has also been employed in doses of two or three grains three or four times a day.

Salicylic acid has been found of service by some. Its beneficial effect is attributed to its action on the mucous membrane.

In Germany, sulphur, rubbed up with a little syrup, is used extensively, and, in fact, in some parts of Germany this is the only treatment employed.

Among other things which have been used, may be mentioned tincture of cantharides, in very small and frequently repeated doses well diluted; infusion of chestnut leaves, in the proportion of one ounce of the fresh leaves to a pint of water, and the patient allowed to drink freely of it; also ergot.

The picrate of ammonium is another substance which is supposed to act on the germs. It has been given in the dose of one-twentieth of a grain four or five times a day.

In Europe, the use of calomel has been revived. Small doses of calomel with bicarbonate of sodium and sugar of milk are placed on the tongue. It is supposed to act directly on the mucous membrane while being swallowed.

Lastly, I speak of counter-irritation. This is an important measure. A well-known application consists of croton oil, oil of amber, and oil of cloves. These oils may be mixed with soap liniment or sweet oil and rubbed on the neck or chest three times a day, afterwards covering the surface with oiled silk.

There are so many remedies recommended in the treatment of this disease that we are sometimes at a loss to know how to begin the treatment. In an ordinary case, the use of the spray is of great importance, and no case should be treated without it. With the spray may be applied some of the remedies already referred to, using them in succession until one is found which has a good effect. Small doses of belladonna with alum and bicarbonate of potash may be given during the day to act on the mucus and relieve the paroxysms, and at night a dose of some sedative should be administered to promote sleep. Frequently an enema of ℥j of lac asafœtida will be sufficient. To this should be added the use of a counter-irritant as already recommended.

You should see that the child's bowels are regularly open, either by incorporating fruit with the diet, such as stewed apples or pears or prunes, or an orange before breakfast. Possibly it may be necessary occasionally to give some laxative, such as Philip's milk of magnesia, the syrup of Rhamus purshiana, or once in a while a dose of castor oil.

If the bronchitis be at all severe, the lungs should be carefully watched, and flaxseed meal poultices or flannels wrung out of hot water and covered with oiled silk be applied. In milder cases, a cotton or woollen jacket (carded wool) is to be preferred. When possible, cod-liver oil should be administered, or it may be used in liniment.

As to diet, the most nourishing and easily digested food taken is of course the best. The vomiting may be severe, owing to the constant gagging from the cough. Peptonized milk or gruels, beef peptones, meat jellies, broths, and eggs are the most useful. Milk punch should not be omitted.

ORIGINAL ARTICLES.

REPORT OF A CASE OF SO-CALLED HAY FEVER, TREATED BY THE GALVANO-CAUTERY.[1]

BY RICHARD HENRY THOMAS, M.D.,
PROFESSOR OF DISEASES OF THE THROAT AND CHEST IN THE WOMAN'S MEDICAL COLLEGE OF BALTIMORE, ETC.

UNTIL a comparatively recent date, the treatment of hay asthma has been conducted either upon the plan of using palliative measures in the form of local applications, or of internal treatment; or upon the theory of banishing the patient to some place, such as a mountain top or barren island, where there would be freedom from the exciting cause, there to remain till the dreaded season should be over. We believe that most observers admit the exciting cause of this distressing complaint to be some external irritant, such as the pollen of grasses,[2] which, coming into contact with the sensitive and erectile tissue of the nose, sets up an amount of irritation and inflammation there sufficient for the other phenomena of the disease, which are, in fact, only reflex phenomena. That it is not purely a nervous disease, is shown by the rapid subsidence of all symptoms soon after the removal of the patient from the influence of the exciting cause, and by their return, when the patient is even unconsciously exposed to its action. As a good example of this, I remember the case of a lady, who, having gone to a seaside place specially recommended on account of its barrenness, was much surprised to find herself suffering so much from her trouble during the first night. On arising in the morning and looking out, she saw there was a garden by the house, of which, as she had arrived after dark, she had been entirely unaware.

Although removal from the cause gives positive relief, most can ill-afford such prolonged banishment from the business of life; and when, as in the case which I am about to relate, the affection lasts from the beginning of June to the end of August with great violence, the question as to what is to be done becomes very serious.

I do not consider it within the scope of this paper to speak of the various local and general remedies that have been tried and recommended. Suffice it to say, that most of them afford temporary relief to some, while to others they are without influence. A few seem to be greatly relieved by them. In general, I have noticed that chronic sufferers are slow to believe in any cure other than the relief afforded by temporary exile.

But the external excitant is, of course, only one link in the chain of causes that produce the disorder. A very important link is formed by the chronic disease in the nose which is always found in those

[1] Read before the Clinical Society of Maryland, Jan. 16, 1885.

[2] The pollen of grasses is, of course, only one of many excitants. I have now under my care a lady who is suffering from this disease, who is never so free from it as during the summer. In her case, the attacks are brought on by dust, bad odors of any kind, etc. In the case of a colored man, who lately presented himself at my clinic, attacks were brought on whenever he entered a room where oysters were being opened.

affected with hay fever. It is very possible that the patients themselves may not be aware of the existence of any trouble of the kind between the attacks. They will say: "I am quite well, except during the season." This is probably owing to the fact that, compared with their sensations during the acute affection, they feel well for the rest of the year. Nevertheless, examination by the rhinoscope reveals the presence of diseased tissue, and it has been found that when certain parts in the nose, sometimes over the turbinated bones, sometimes on the septum, are touched with a probe at any time during the year, all the symptoms of hay fever will momentarily return. The most frequent condition found is hypertrophied tissue over the turbinated bones, especially the inferior, and over the septum. This may be comparatively slight, or so great that breathing is interfered with through the nose. In addition to this, polypi and other growths are often noticed, or a projecting spicule of bone, or a deflected septum. We can see, therefore, besides the individual susceptibility of certain people to irritation of this kind, the exciting cause needs an abnormal condition of the nasal passages to enable it to produce an attack of so-called hay fever. If, then, we remove this unhealthy condition, the chain of cause and effect in the production of the disease is as surely broken by the breaking of this link as by sending the patient to some barren island.

With Dr. Roe, of Rochester, N. Y.,[1] and others, I fully believe that this method of removing the susceptibility is the most satisfactory and positive method of cure. In fact, it is the only method of cure, as all other procedures are only temporizings. It consists in local treatment, and small operative procedures. Of course, everything calculated to excite irritation must be removed. If the septum be markedly deflected, it must be straightened; a projecting spicule of bone must be removed, as well as any polypi or other morbid growths. The hypertrophy which is nearly always present, if large enough, should be removed by a Jarvis's or other snare. If the snare is not applicable, caustics should be used, of which the galvano-cautery is, in my opinion, decidedly the best. Besides this, any point of irritation, as discovered by the probe, should be touched by the galvano-cautery, using only a very small tip. In some cases, as those described by Dr. Roe, in which there seems to be no hypertrophy, and the only sign of disorder is the irritation caused by the probe, this last is all that is required.

As to the time of treatment: for the cure, the best time is between the attacks, as there is then no risk of increasing the irritation. After the main treatment is over, it is very desirable for the patient to be seen during the next hay fever season, so as to touch any small remaining areas of irritation with the galvano-cautery tip, and render the cure radical. The following case is of special interest, owing to its unusual severity, the attacks being so severe as almost to endanger life.

B., an English gentleman, aged 22, unmarried. Since early childhood he has been subject to a certain amount of nasal catarrh, and for a long time—he cannot fix the date, has been unable to breathe for more than a minute or two at a time through his nose. About six years ago, he noticed an increase in his catarrh during the summer. Every year it has grown worse, commencing about the 1st of June and continuing till the last week in August. The attacks assume the form of asthma; and when they are at their height, he is unable to sleep or to lie down. Cannot walk across the room without increasing the dyspnœa. Many remedies have been tried, with only temporary relief, and last year the attack, after lasting a long time, culminated in catarrhal pneumonia, which left him so weak and delicate that he was unable to return to his business till November.

This summer (1883) the asthma returned with increased violence, and his physicians, fearful of a repetition of the experience of the previous year, recommended a sea-voyage. He landed in New York, July 18, 1883. This was just as I was starting on my summer vacation, and so, having been informed of his coming, I met him at the wharf. After the second day of the voyage, he had been entirely relieved of his asthma; but so sensitive was he that he had not been more than three hours in the city before he began to suffer from dyspnœa, and the usual accompaniments of the disorder. That evening, I took him by boat to the Island of Nantucket, knowing that there was a special place on the island, called Wauwinet, where he would probably be free from his trouble. There was very little vegetation near the little hotel, and, as the strip of land between the harbor and the sea was only a few hundred feet across, every breeze was by necessity a sea-breeze. Here he was quite relieved, except when a bunch of flowers was brought near him, when he would at once begin to feel suffocated. The disease, however, though it gave him no trouble, was only held in abeyance, as I had opportunity to observe by the rhinoscope, the tissues of the nose being in a state of very active hyperæmia.

Early in September, he came to Baltimore for treatment, but the extreme irritation of the Schneiderian membrane rendered it inadvisable to commence active local treatment at once. I therefore ordered full doses of quinine and had him evaporate "vapo cresoline" (a preparation of coal-tar) in his room at night, at first for an hour or so before retiring, and, later, through the whole night. This proved very satisfactory in lessening the irritation. The condition of the parts at this time was as follows, viz.: Very marked hypertrophy over the middle and lower turbinated bones anteriorly and posteriorly, not, however, projecting into the naso-pharynx; adenoid growths in the vault of the pharynx; follicular pharyngitis, and also chronic laryngitis. These last were evidently secondary to the naso-pharyngeal disease. Repeated examination of the heart and lungs showed both to be healthy. On October 4th, after some local treatment, consisting of applications of dilute spts. vini rect. to the nose and iodinized glycerine or solutions of argent. nit. (gr. xl–lx ad ℥j) to the pharynx, I made the first application of the galvano-cautery to the tissues over the right inferior

[1] New York Medical Journal, May 12 and 19, 1883, and May 3 and 10, 1884.

turbinated bone anteriorly.[1] Subsequent applications of the same kind were made to the hypertrophied tissues anteriorly and posteriorly. The posterior applications were made through the mouth under the guidance of the rhinoscopic mirror. The snare was not used during the treatment. The enlarged follicles in the pharynx were touched in the same way, and the adenoid growths removed with the forceps. The following precautions were observed in making the galvano-cautery applications, viz.: For a day or so before and after, I administered full doses of tinc. ferri chlor., and never made a second application in the vicinity of the first till all the irritation caused by the first had subsided. He returned home on the 21st of November.

The following are from my notes of his condition for several weeks before he sailed: He can breathe with perfect ease with closed mouth, and is able to read aloud with a facility before unknown. He has no special susceptibility to cold, and is able to bear exposure to inclement weather and night air. Even if he catches a slight cold, he is able to throw it off with ease. He says he is better than he ever was in his life.

He passed the winter with decidedly improved health and with very much greater freedom from any bronchial trouble. In the spring he exposed himself on several occasions to special risks, and had an attack of subacute bronchitis, which, however, passed off before the time for the hay fever. About the same time, he moved to Liverpool, choosing a room with but little sunlight in it.

I heard from him repeatedly during the dreaded period, and learned that he was hardly troubled at all. On one occasion, at the end of a short visit to one of the most thickly wooded districts in England, he felt a tingling in his eyes and for three days had a slight cold in his head. In August, for a few days he feared he would have a return, but it also passed off. His usual three months of suffering, therefore, were shortened to a few days' comparative discomfort. His was the worst case of this disease which I have seen, as the sequelæ of the last attack absolutely threatened his life, and thus I think it amounted to a test case.

ON THE SURGICAL DISSEMINATION OF CANCER.[2]

By A. G. GERSTER, M.D.,
of New York.

The subject in question not being mentioned by the authors of text-books on general and special surgery, and unknown in periodical literature, seems of sufficient importance to deserve consideration. The present essay is an *a priori* consideration of the possibility or probability occurring in the course of the development and treatment of cancer; an outline of a train of thought based on clinical observation that may deserve more extensive study in the future.

The subject-matter itself is not strictly new, observations bearing upon it having been made and published from time to time in an unconnected manner. The leading idea of this essay was originated in the year 1877, by observing the course of a striking case of rapid dissemination of cancer. Since then a number of other cases have accumulated, tending to confirm those first impressions, when, finally, Czerny's observation (published in 1883), and König's remarks on operative dissemination of tuberculosis (published in the *Centralblatt für Chirurgie*, 1884), appeared, the interest of the author was quickened by their strong confirmatory, though indirect, evidence.

They both, like the author, did not advance anything absolutely new, as everybody knows that many patients operated on for joint-tuberculosis die subsequently, and soon after the operation, of meningeal, or other forms of disease. But they drew attention to the fact that the *post hoc* may be in many cases also a *propter hoc*.

The author's case in question was as follows: An aged lady, of robust health, and cheerful, intelligent disposition, presented herself for treatment on account of an elevated ulcer of the outer margin of the sole of her right foot. It had existed for over thirteen years, growing very slowly, until it had attained the size of three inches by two inches and a half in diameter. It was segmented, each segment showing a distinct epidermal margin, the edges of the ulcer overlapping somewhat the normal skin. While open, the purplish-red ulcer discharged large quantities of a clear serum, but if the patient refrained from walking it readily cicatrized over, to become sore again on her using the foot. Previously the pain or inconvenience was very slight, and no glands were infiltrated. Lately, however, the sore had become very painful.

Excision was proposed, and carried out in the fall of 1877, when the base of the new growth was found to be attached to the plantar aponeurosis, which accordingly had to be removed too. The wound healed rapidly by granulation, the diagnosis of granuloma made previous to the operation, and based upon the benign development of the disease, was confirmed on microscopical examination made by Dr. I. Adler, of this city. A favorable prognosis was expressed, and the patient was encouraged to use her foot. Immediately upon cicatrization being completed, a number of small, purplish, pigmented nodules made their appearance in and about the scar, and well up the leg, increasing daily in number and size. Any doubts about the formidable character of the new growth were dispelled then, and a high amputation of the thigh was at once proposed, but declined by the patient, who, however, finally submitted to the operation in May, 1878. A mass of enlarged glands was also removed from below Poupart's ligament. Both wounds healed by the first intention, but the operation did not delay the patient's impending fate. A few days after the removal of the limb the patient inquired about the significance of a disturbance of vision, which she had noticed for four weeks, but in her excitement preceding the amputation omitted to mention it to the author. It will suffice to say that a retrobulbar node, causing first diplopia, finally pro-

[1] The instrument used was the improved Seiler cautery instrument.

[2] A paper read before the New York Surgical Society, February 10, 1885.

truded the eyeball from its socket in a frightful manner, and that the entire body of the patient became covered with innumerable nodes and nodules in an astonishingly short time. The patient's death by suicide fitly closed the tragedy, which did not fail to make upon the author a deep and lasting impression. Post-mortem examination revealed that all the organs, especially the viscera, were permeated with thousands of nodules of pigmented cancer.

Undoubtedly, then, we must have had originally a true granuloma, which at the time of the first operation was undergoing the not unusual change into cancer; some portions of the tumor then removed still presenting the character of a connective-tissue growth, as Dr. Adler's examination had proved. But is the fact of this change of a benign into a malignant neoplasm alone sufficient to explain its astonishingly swift dissemination? Certainly not, as all processes of dissemination observed in malignant new growths, local and systemic, are notoriously slow, and not to be compared with that in the foregoing case. By "slow" is understood a spread in *étapes*, as the French say, on marches, to use a strategetical term. That is, a nidus which is not continuous, but interrupted, is characterized by well-defined phases of activity and seeming rest.

First comes the simplest and most immediate spread by contact with neighboring tissues, which generally lasts for a considerable time, but soon is followed by the second phase; that is, that of the infection of the adjacent lymphatic vessels and glands. These serve as a barrier for a certain period of time, till a large vein becoming involved, transplantation by embolism extends the disease to one or more rather distant organs. This last one would form the *third* or *generalizing* phase of infection.

In the case related, local and general dissemination seems to have taken place simultaneously, and in a manner closely resembling certain physiological and pathological experiments performed on animals, where substances capable of multiplication are injected into the parenchyma, or directly into the circulation. The assumption of a mechanical, rapid distribution of the infective bodies is almost imperative, and this rapid mechanical distribution of the infective elements may have been accomplished by the manipulations incumbent upon the performance of the operation.

Observations similar to, if not as poignant as the one related, have multiplied in the experience of the author, extending over forty cases of amputation of the breast made since the year 1878, and the practice of every busy surgeon must yield a not inconsiderable number of instances of the same character. As none of the cases of this character possesses the elements of proof positive, it would be unnecessary to weary your patience by records of similar cases, but it is important to tell you that the practical wisdom of an older generation of surgeons has impliedly admitted the truth of our assumption by advising amputation of an extremity afflicted by what was then termed "cancer," in preference to a mere extirpation of notoriously malignant growths. And the value of this advice is twofold: First, it more surely eliminates all foci of disease than a however comprehensive excision; and last, but not least, the field of operation being more or less distant from the seat of the disease, handling of the tumor and manipulative dissemination of its elements are less likely to occur than otherwise.

Now let us consider what amount of force and energy is employed in the handling of tumors by physicians, and whether this handling does not possess some or all the characters of that form of manipulation which the French denote as "massage."

A careful physical examination of a tumor, especially if made by the aid of anæsthesia, will be, and notoriously is, frequently accompanied by the use of a good deal of necessary or unnecessary force. The handlings or manipulations ordinarily in use during the performance of bloody operations on tumors, to be dissected out of surrounding tissues, have positively the character of massage, and occasionally a very rough form of massage, too. And the employment of anæsthetics has certainly not had the effect of increasing the gentleness of operative interference. Suffice it to say that the manipulation employed on a tumor of the breast and the lymphatic glands occupying the adjacent axillary cavity during an operation lasting one or two hours, certainly may have the dignity of a manipulative séance. And all of you know that a skilful massage of thirty minutes will often cause to disappear a massive extravasation of blood from the vicinity of a sprained joint, and that three or four sittings may dispel the largest part of a solid infiltration of an inflammatory character from this or that part of the body. Now just bear in mind how many formed corpuscular elements, be they cells or broken-up portions of a firm clot, must be propelled through the lymphatics and veins into the general circulation at each massage, and the idea of the probability of the propulsion of cancerous elements of an unfixed, minute, that is, embryonic character, and situated especially in recently involved places about the margins of a tumor, is very plausible indeed. The analogy of these artificial processes is *a priori* evident, and the fact that mechanical irritation, that is, another form of massage, favors the spread of malignant disease, stands fully in accord with this assumption. Finally, it seems appropriate to adduce here Billroth's authority as a pathologist in these, his words: "I consider it most highly probable that both the continuous and the discontinuous spread of carcinomata is effected (*vermittelt*) by the dissemination of corpuscular elements, but admit that so far we are unable to prove this in all cases.[1]

The author does not wish to have it understood as if he considered this mode of dissemination the rule, but he believes that in a number of cases of malignant disease operative treatment may hasten, rather than retard, death. This statement seems to contradict the results of statistical investigation as laid down by such authorities as Von Winiwarter and Gross, whose meritorious works are well known to all surgeons. But this contradiction is partial only, and is justified by the nature of statistical results in general, which we know are arrived at by summing together

[1] Deutsche Chirurgie; Krankheiten den Brustdrüsen, S. 112.

cases widely different in character, though all representing the same disease.

Our critical attention will necessarily be first directed to the comparative estimates by averages of the duration of life of patients operated on for cancer of the breast, and patients not subjected to operative treatment.

Here we see that Winiwarter finds the average duration of life from the beginning of the disease of the operated cases to be about 39.5 months, whereas that of patients left to their fate is almost 33 months. The operated cases, accordingly, live on an average about six and a half months longer than those not coming under the surgeon's knife.

On further examining the figures it will be remarked at once that the number of observations of non-operated cases is very small as justly compared with those operated on, one being 97, the other 519. Take into consideration, furthermore, that many, if not all, of the non-operated cases were subjected to all manner of irritative treatment, greatly influencing their rapid development and dissemination. Finally, that many of them may and have been such as show a formidably malignant character, deterring even the boldest operator, so that it will be easy to comprehend that the rate of mortality as calculated for these 97 cases is unreliable and too high if applied to all cases of unfavorable cancer, many of which not being malignant did not come under observation at all. But, let us analyze the cases subjected to operation. Here we find that somewhat over *nine per cent.* were permanently cured by the operation, They necessarily must have been such in which a complete removal of all diseased tissues was successfully accomplished. It is of the utmost importance to note that such a thing is possible under certain favorable conditions, offered by an early and very thorough operation of a not extensive tumor of comparatively slow growth. Clinicians know and admit differences of infection in cancers which depend upon a more or less rapid growth, and accordingly upon a greater or less proportion of succulency attributable to more or less embryonic, non-fixed or movable tissue components or corpuscular elements. Their anatomical expression is a greater or less proportion of *cancer juice*, as produced by scraping of their cut surfaces with a scalpel.

To go back to a former comparison, we may say that as the corpuscular or liquid elements of a recent succulent inflammatory infiltration are more easily dispersed by massage, so will the elements of a succulent cancer be more prone to be dispersed by mechanical factors, and we may add that their rapidity of reproduction also stands in direct proportion to the ease with which they are dispersed. This relationship suggests resemblance to a geometrical progression, and may serve to explain the enormous differences of malignity observed in cases standing at the foot and at the head of the statistical scale respectively. Gross mentions an unoperated case that terminated fatally at the expiration of five months. Billroth gives the history of one that lived for twenty years.

To return to the cases cured permanently, we may say that a few of them may have been very malignant, but that most of them were not very malignant and were subjected to a very radical operation: finally, that in all of them up to the patient's death from other diseases, no formation of cancer *de novo* had taken place. (It is still a mooted question whether even a regional recurrence of cancer three or more years after operation is a continuation of the old process, or a new disease *per se.*)

The large majority of the 368 operated cases, that is, nearly 81 per cent., showed recurrence. In eleven and a half per cent. of the 368 cases, recurrence took place after twelve months; but it does not appear in what manner or where. It would be important to find whether the general character of these recurrent tumors was mild or severe, local or general, and what was their microscopical nature (succulent, or firm and dry).

Presumably these were mostly tumors of not great malignancy, or of a slow growth, incompletely removed, yet so that very few cancerous elements were left behind to multiply.

It may be pertinent here to mention the curious fact, though no explanation of it is ventured, that seemingly infected glands have been seen to disappear after the removal of the primary tumor in such cases even where the knotty, hard nature of the glandular swelling fully justified the assumption of its cancerous character.

Within three months sixty-three per cent. of the cases relapsed, forty-three per cent. within *four weeks*, and nineteen per cent, even before the lapse of a *fortnight.*

In about 82 per cent. of 194 cases of recurrent cancer in which this point was noted, the locality of the relapse was in the cicatrix, remains of mamma or vicinity, and in the glands.

These figures are appalling; they show that in almost two-thirds of all operated cases relapses are established within three months after the operation. Undoubtedly the great majority of these cases represent very incomplete operations, where already disseminated portions of the neoplasm were left behind, either in the vicinity of the primary growth, or in or about the infected lymphatic vessels and glands. The cases relapsing within four weeks (43 per cent.), and still more, those recurring within a fortnight (19 per cent.), must be such where either incomplete operations were performed, or where artificial operative dissemination took place, or finally where both of these influences combined to cause a rapid involvement of hitherto seemingly healthy tissues. We have to add, finally, while treating of this group, a class of cases characterized by Billroth in the following words: "Cases operated on under seemingly very favorable circumstances, in which, however, the patients are already victims of internal carcinoma, this becoming evident on post-mortem examination made soon after the operation, are unfortunately *not very rare.*" [1]

Of course, the occurrence of such cases cannot be gainsaid, but considering the gradual extension of cancer observed as a rule, such an infection by a jump, as it were, must nearly always be caused by

[1] Loc. cit., p. 117.

mechanical factors. By these are meant either a build and arrangement of the lymphatics usually favorable for the easy transmission of corpuscular elements, or a very energetic and effective external agency, such as a traumatism, or massage, or long-continued compression, or all of these combined.

But to return to our subject, we will say that Von Winiwarter does not state whether a change in the character of the malignancy of these neoplasms was observed or not on their recurrence after operation. And herein all observations are strangely defective, and unfortunately so, as this seems to constitute the nodal point of our inquiry. If it were shown that in a certain number of tumors of previously slow growth, a fast and extensive *local* recurrence took place immediately after a comprehensive and thorough-going operation, performed by a competent and experienced surgeon, it would be necessary to assume the concurrence of a factor hitherto unknown, even unthought of. And if the marginal portions of the removed tissues were found, on careful and exhaustive examination, to be entirely free of such miliary foci of cancer as can be detected by the microscope, the presumption of a direct influence upon the nature and course of the disease, by the operation, would be almost imperative.

Older surgical writers directly admit the possibility of such an influence; modern authors, as, for instance, Billroth and Volkmann, only by inference; and their reticence in this respect is easily explained by the lack of a sufficiently large sum of observations collected with a view to the ascertainment of this very point: and by the necessity of questioning the correctness of the generally accepted assumption that the operated cases show a much longer average duration of life than those let alone.

Let us now examine what this peculiar "influence" of operative or other mechanical irritation upon a cancerous growth may consist in. Excluding chemical irritation, and taking in view only forms of irritation considered to be more strictly mechanical and akin to massage, we find that this influence may be twofold. On the one hand, it may induce active hyperæmia, a better nutrition of the tumor, and hence a more rapid multiplication of existing elements *in situ*. On the other hand, and following from the first, it will increase the activity of the lymphatics, and fitly prepare them for the reception and transmission of mobile cancerous elements. Finally, the changing degrees of pressure from different sides, and its intermittent character, will not fail, in suitable cases, to propel such cancerous elements to a shorter or longer distance, and if the form of mechanical irritation is constant and frequent, a large area of the surrounding tissues may become injected with cancerous elements in a comparatively short time. Supposing that all this takes place during an operation, followed by an unavoidable stimulation of the thus infected tissues incumbent upon the processes of repair, what wonder if we see a large number of small nodes appear in and about the cicatrix, left after the removal of a solitary tumor, and within a few weeks after the operation?

Instead of assuming a mysterious, indefinable change in the character of the new growth, it is more rational to explain a natural process by natural and well-known biological laws. It may be objected that all operations followed by a rapid and wide-spread reappearance of the disease about the sites operated on, must be such in which preëxisting foci of cancer were unwittingly left behind by the operator. Admitting, as we have done before, that a large number of cases is covered by this explanation, yet we may reply to this with the following question: What is the reason, then, of the simultaneous appearance and rapid growth of a large number of cutaneous foci shortly after the operation on a formerly slowly growing tumor? Why do these foci remain dormant, or grow imperceptibly until the time of the operation, and suddenly come forward after the traumatism of an operation? And there is not only a spread, there is frequently also an increased rapidity of the multiplication of the elements, an increased malignity denoted as a *change of character;* and why this? Our explanation seems to cover these questions.

Besides, it is not impossible that young cancerous cells, sowed, as it were, into new soil, well prepared by an increased blood-supply due to the healing process, will thrive much better in this unexhausted, well-irrigated ground than elsewhere.

Of course, all this does not prejudice the acceptance of the fact that positively benign tumors do change occasionally into malignant ones, but it seems that this important mechanical factor in the growth and dissemination of cancer ought to receive some recognition. The author has begun a series of experiments tending to prove the possibility of mechanical or surgical dissemination. But the results of the investigation of the subject have not matured yet for publication.

Before completing this paper it may be appropriate to point out in a few words its practical bearings. It is not intended to question the general correctness of the advisability of operating on even far-gone cases of cancer. On the contrary, it is hoped that by pointing out one more danger, we may be taught to avoid this also, thereby succeeding more and more to improve the results of the operative measures in this field. Antiseptic treatment has here, too, undoubtedly stimulated active surgical interference, and though the author's material includes only thirty-four radically operated cases of malignant tumors of the breast, that is, such in which the breast and the axillary contents were removed, and partial operations, with no deaths resulting from the operations, this may justify the conclusion that antiseptic measures must have generally depressed the death-rate of 16.5 per cent. as given by Winiwarter.

Nothing need be said about the necessity of early operations, and the very radical, extensive removal of a wide zone of seemingly healthy tissues surrounding a cancroidal tumor. If the neoplasm be on an extremity, and is extensive, the preference should be given to an amputation made far away from the disease. Wölfler has conclusively shown on animals that during the time that Esmarch's constriction is applied to a limb the veins and lymphatics beyond the constricting band are inactive, and do not absorb even soluble substances, and that these do not enter the ostia of the vessels opened up by the sur-

geon's knife as long as the constriction lasts.[1] It seems to be rational, then, always to employ Esmarch's constriction when existing malignant tumors are situated on a limb, since it is improbable that corpuscular elements would be propelled where there is no medium, as blood or lymph, to carry them along. In examining any kind of tumor the utmost gentleness should be observed, and obscure points in the diagnosis not bearing upon the therapy, should rather be left undecided till after the operation. Unnecessary handling of a suspicious tumor should be discouraged, and the patients especially warned against so-called abortive methods of treatment, as painting with irritating chemicals, and especially, the several forms of compression, constant or interrupted.

As a preparatory measure, the hyperæmia and cell-activity of a rapidly growing tumor should be reduced as much as possible by the constant application of ice, or the water coil, for several days preceding the operation, as it is notorious that the growth of some tumors is noticeably retarded by the influence of low temperatures.

During the exsection of deeply embedded tumors all rough handling and pulling to and fro, should be avoided as much as possible. This may be very difficult in cases of large, heavy tumors, or where it is necessary to work in a deep, non-dilatable wound, wherefore the proposal of an English surgeon to fasten into each tumor, after its exposure, a sharp hook attached by rope and pulley to the ceiling of the operating room, seems to be very appropriate. One assistant can easily raise or lower even a very large tumor by traction applied to the rope running through the pulley, while the surgeon himself, holding the shank of the hook, can carry out without fatigue such lateral movements as become necessary in the course of the operation. This would deserve a trial, especially in amputations of the female breast. For self-evident reasons the axillary fat should be invariably removed, and in one mass, this being much easier and safer than the digging out of single glands. The operation should commence, if possible, with the evacuation of the axillary space and its contents, which, together with the breast and the intervening tissues, should be removed in one piece.

Primary union of the entire operation wound should be always aimed at where possible, since suppurative processes, and the increased reproductive activity of the tissues incumbent thereon, tend to cause an early development of such cancerous elements as may have been left behind.

The view that non-destructive suppuration may eliminate such cancerous elements, has no support in pathology. The surgeon should rather use his knife freely than invoke the aid of such a treacherous ally as suppuration.

OBSERVATIONS ON NIGHT-COUGH, ESPECIALLY IN YOUNG CHILDREN.

By ALEXANDER W. Mac COY, M.D.,
of Philadelphia; surgeon to throat and nose department of the Philadelphia dispensary, etc.

It is the common experience of physicians to meet many cases (in young children chiefly) of an obstinate and irritative cough, which is particularly active at night, and which has led practitioners a devious path in the attempt to medicate it successfully. This irritative cough has caused much anxious solicitude to parents, and has brought to many little ones days of lassitude by reason of broken sleep. It appears to me that the *true* nature and cause of many of these irritative, hacking coughs have been overlooked or underestimated; nor can successful management be expected until the pathological factor present is fully appreciated.

The majority of children who have this annoying symptom at night show no appreciable illness during the day, nor is the cough then often present. Close surveillance only will detect an occasional clearing of the throat in older children; in the younger ones, occasional attempts at swallowing. In certain cases escape of mucus from the nostrils may be seen, while others require a critical inspection of the nasal chambers to reveal the presence of discharge. It is often appreciated that the child has a "cold in the head," but that any causative relation exists between the condition of the nasal passages and their products and *the cough* is not imagined.

It has been so long the rule to ignore affections of the nose in adults that it is not to be wondered at that the mucous membrane of the nasal passages in children should receive so little attention. I am convinced that there will be a complete revolution in our ideas of diseases of the nose and naso-pharynx in their *relation* to diseases farther down in the upper air-passages; and that the nasal cavities will become most important factors to be considered in properly appreciating affections of the larynx, bronchi, etc. A considerable experience in this class of cases has led me to formulate the following propositions: 1st, that many coughs are *not* dependent upon any inflammatory or catarrhal processes in larynx or bronchi; 2d, that they are *not* generally dependent upon prior enlargement of the tonsils or pharyngitis; but, 3d, that they *are* dependent solely upon a nasal catarrhal inflammation with its accompanying secretion.

It has been demonstrated by Dr. John N. Mackenzie and others that certain areas of the nasal chambers are quickly responsive to irritants or stimulants, and that mechanical irritation applied to the regions embraced by the turbinated bodies and septum posteriorly, will quickly cause an explosive act *quite* like a cough. I have also demonstrated, to my own satisfaction that the reflex cough area is not at all confined to these regions,[1] but that in a large proportion of cases, the anterior portion of the septum and vault of the nose are highly sensitive to irritants and constitute a remarkable active area of sneezing and cough. I have cases to show that the mucous membrane covering the vault or bridge of the nasal chambers, and a portion reflected upon the septum, is chiefly concerned in the production of hay asthma, serous catarrh, etc. Now, if we bear in mind these interesting facts concerning nasal cough and its production, as well as the more common occurrences of mechanical cough, we can easily accept the doctrine herein advocated.

[1] Confirmed by Hack, Wien. med. Wochenschrift, 1882-83.

The rationale of the attacks of night-cough occurring in children (and adults also), as soon as the recumbent posture has been assumed, is, that while the child is in the erect position during the day, gravity lends its force to *facilitating* the escape of the secretion from the nasal passages, either through the nostrils or posterior nares, assisted by the functional activity of the fauces, palate, larynx, etc. But at night the child retires with an accumulation of more or less discharge in the nasal passages, or some is secreted after a few hours. The child is lying down, and the effect of gravity then is to aid the discharge in gradually escaping from the posterior nares, when it forms an elastic pellicle which gradually lengthens out and slips downward along the pharyngeal wall until the free edge of the epiglottis is touched by it, when instantly the interference is resented—a cough expressing it. Again and again the effort is repeated; a constant hacking cough supervenes from this purely *mechanical* irritation. If the pellicle of mucus passes the epiglottis, it lodges upon the posterior or arytenoid portion of the larynx, and gives rise to the same symptoms. The pellicle of mucus may still be attached high up in the naso-pharynx, and being very tenacious, it can be readily understood how the cough may be kept up for hours before the mucus becomes detached and passes beyond the larynx.

It is a well-known fact that a drink given to the child will often cause a cessation of the paroxysm, the fluid simply pushing downward the exciting foreign body. This clinical fact gives us the clew to the successful management of these troublesome cases. If the nasal passages are thoroughly cleansed before the child is put to bed, the night will probably be uninterrupted by this irritative cough. If the discharge accumulates in the nasal passages or upper pharynx during the night and gives rise to a paroxysm, it is a simple procedure to cleanse the nasal chambers, and at once relieve the symptoms. Treatment can be most effectively carried out by means of a spray composed of an aqueous solution of an alkali. By its use these cases need no longer be harassing to either practitioner or patient.

1417 Walnut Street.

MEDICAL PROGRESS.

The Relation of Bacteria to Asiatic Cholera.—The investigations of the English Cholera Commission as to the relation of bacteria to Asiatic cholera has, according to Dr. Klein, ed to the following conclusions:

1. Koch's statement as to the constant occurrence of comma-bacilli in the rice-water stools of cholera patients is correct; the comma-bacilli vary greatly in numbers in different stools and in different cases, in some being exceedingly scarce, in others numerous.

2. These comma-bacilli vary greatly in length, some being twice and three times as long as others, some well curved, as much as to form half a circle, others showing only just a slight bend. The name comma-bacillus is inappropriate; the organism is more correctly termed a vibrio.

3. The comma-bacilli occur in the mucus-flakes of the rice-water stools, as well as in those taken from the ileum of a person dead of cholera. The sooner after death the examination is made, the fewer comma-bacilli are found in the mucus-flakes; even in typical rapidly fatal cases, the mucus-flakes taken from the ileum, and examined soon after death (from between fourteen minutes to an hour or an hour and a half), contain the comma-bacilli only very sparingly indeed, and not to the exclusion of other bacteria. Our investigations do not bear out Koch's statement as to the lower part of the ileum being, in acute typical cases of cholera, almost "a pure cultivation of comma-bacilli." In not one of the many post-mortem examinations of typical acute cases have we found such a state.

4. The mucous membrane of the ileum, in typical, rapidly fatal cases, if examined soon after death, does not contain in any part any trace of a comma-bacillus or any other bacteria, not even in the superficial loosened epithelium. If the post-mortem examination be sufficiently delayed, comma-bacilli and other bacteria may be found penetrating into the spaces of the mucous membrane. Koch's theory as to the comma-bacilli present in the mucous membrane secreting a chemical poison inducing the disease cannot, therefore, be correct.

5. Neither the blood nor any other tissue contains comma-bacilli or any other microörganisms of known character.

6. The behavior of the comma-bacilli in artificial media is not such as to justify their being considered as specific. They grow well in alkaline and neutral media, are not killed by acids, and their mode of growth in gelatine-mixtures is not more peculiar than that of other putrefactive bacteria; they show marked differences when grown in different media, but not more so than the ordinary putrefactive bacteria when compared in their growth with one another. The comma-bacillus of the mouth shows the same peculiar character of growth in gelatine as Koch's comma-bacilli.

7. Koch overlooked the fact that "comma-bacilli" occur in other intestinal diseases, in the mouths of healthy persons, and, as shown recently, even in some common articles of food. (By Dr. Deneke in stale cheese.)

8. The experiments performed by Koch and others on animals do not in the least prove that the comma-bacilli are capable of producing cholera or any other disease. The results obtained by them are much more easily explained in an opposite manner.

9. There is direct evidence to show that water contaminated with choleraic evacuations, and containing, of course, the comma-bacilli, when used for domestic purposes, including drinking, by a large number of persons, did not, in the case of the tanks near the Jelepara Lane, produce cholera.

10. The mucus-flakes taken from the small intestine of a typical, rapidly fatal case of cholera, contain numerous mucus-corpuscles filled with peculiar minute straight bacilli; in this state they are found when the examination is made very soon after death; soon, however, the mucus-corpuscles swell up and disintegrate, and then their bacilli become free. The small bacilli are never mixed in the mucus-flakes. They are one-third or one-fourth the length of the comma-bacilli, and about half

their thickness. They are non-mobile; they grow well in Agar-Agar jelly, but show in their modes of growth no peculiarity by which they could be considered as specific. When grown on the free surface of the nourishing material they form spores.

11. These small bacilli are not present in the blood, in the mucous membrane of the intestine, or in any other tissue.

12. Experiments made with these small bacilli on animals produced no result.

13. Since his return to London, Dr. Klein has ascertained that the comma-bacilli of cholera show two distinct modes of division, one the known one of transverse division, and a second one of division in length. When growing in Agar-Agar jelly at the ordinary temperature of the room, after some days the bacilli swell up, owing to the appearance in their protoplasm of one or more vacuoles; as these vacuoles increase, so the comma-bacilli become gradually changed, first into plano-convex, then into oblong biconvex, and ultimately into circular corpuscles. The longer the original comma-bacillus, the larger the final circle. These circular organisms are mobile, just as are the comma-bacilli; and, by disintegration of the protoplasm at two opposite points, two perfect more or less semicircular comma-bacilli are formed. Growing the comma-bacilli in Agar-Agar jelly kept at higher temperatures (30° to 34° C.), the comma-bacilli multiply by transverse division only; but, transferring these to Agar-Agar jelly, and keeping this at the ordinary temperature of the room, they again gradually change into circular organisms, which, by division in the diameter of the circle, form two new comma-bacilli.—*British Medical Journal*, Feb. 7, 1885.

DIGITAL DILATATION OF THE PYLORUS.—DR. PIETRO LORETA has successfully practised dilatation of the pylorus, for the cure of stenosis, in five cases, from which he concludes:

1. Digital dilatation of the pylorus should be a recognized operation in practical surgery, since it may radically cure stenosis, consecutive to obstacles lying in the pylorus, cicatricial stenosis, displacements of the pylorus, foreign bodies, echinococci, tumors, etc.

2. Cicatricial stenosis and other causes of obstruction to the passage of chyme should be eliminated from the number of diseases for which resection of the pylorus is indicated, and that operation should be replaced by digital dilatation as being more easily performed and less dangerous in results.

3. Experiment proves that continued sutures (in the stomach) are permanent and efficacious, and that the action of the gastric juice upon them has no injurious effect.

4. Experimentation shows, also, that incisions made (in the stomach) for the extraction of foreign bodies, should immediately be sutured, so that the risk of establishing a gastric fistula, which is frequently dangerous and rebellious to treatment, may be avoided.—*Revue Médical*, Jan. 10, 1885.

SUGGESTIONS AS TO THE METHODS OF USING COCAINE.—DR. E. R. SQUIBB in *Ephemeris* of January, 1885, makes the following practical suggestions as to the manner of using cocaine for local anæsthesia:

In applying the solution to other mucous membranes than those of the eye, a camel's-hair pencil has generally been used, but under the very best management, and upon surfaces made as dry as possible, the pencil leaves but a very small quantity upon the surface, and it is not to be expected that complete anæsthesia is easily attainable in this way, however frequent the applications, and a profuse use of the agent does no good, since it immediately runs off the surface. Neither is it of any use to apply it to surfaces coated with secretions, no matter how thin the coating, if they are of the glairy kind, since efficient contact with the surfaces is then impossible, and the waste is as complete as an application to the skin covered by epidermis. So, on its application to painful ulcers, burns, etc., care must always be taken to obtain contact of the solution by having the surfaces perfectly clean. In applying it to denuded surfaces and to mucous membranes which will admit it, the best method is to have some light covering of the desired shape and size, that will hold the solution For this purpose fine thin cotton or linen fabric is much better, and nothing can be better than well-worn fine handkerchief material. This is sufficiently absorbent to hold the dose, and thin enough to avoid waste, and to be closely applicable to irregular surfaces. When touched in situ, for resupply, the brush should be applied to the upper edge of the tissue, so as to run down through it before draining off, and the smallest possible quantity should be applied at a time if waste by running off would be avoided. Much solution is wasted by the use of camel's-hair pencils many sizes too large. Indeed, it is hardly possible to get a brush too small to convey this solution economically, unless large surfaces are to be coated. In the use of a brush for applying the solution it should never be dipped into the vial of solution, because it carries back secretions and excretions, which rapidly spoil the remaining solution, and it is thus wasted. The proper way is to drop out the quantity to be used on the bottom of a tumbler or wine glass, and dip the brush in this until it is all used, never putting any back into the vial. In this way any desired quantity may be used and none be spoiled or wasted. From reading the published accounts of the application of the solution, it seems highly probable that more of it is wasted than is really utilized, and if this waste could be stopped without increasing the number of failures, the price of the chemical would soon come down.

THE GONOCOCCUS AND THE ABORTIVE CURE OF BLENORRHAGIA.—DR. DOMENICO BARDUZZI, in the *Tip. Vanucchi*, 1884, admits the causative relation of the gonococcus in the production of blenorrhagia, and considers injections of corrosive sublimate of abortive value in the disease if practised on the first or second day after its appearance. The strength of the solution recommended is from 1 : 9000 to 1 : 3000, according to the toleration of the patient. He recommends injection of one-half of a teaspoonful of the fluid into the urethra three times a day, and cautions against making the least effort to throw it into the deep portion of the urethra. Of six cases treated, only one passed to the acute period. In the five remaining cases, the disease aborted completely within four days. For sake of precaution, the injection was continued a day longer.—*Giornale Italiano delle Malattie veneree e della Pelle*, Nov. and Dec. 1884.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, FEBRUARY 28, 1885.

THE TUBERCLE BACILLUS AT THE ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

PERHAPS the most important discussion which has taken place in the English language, on the subject of the bacillus tuberculosis, occurred recently at the Medico-Chirurgical Society of London, when DR. PERCY KIDD read a paper "On the Distribution of Tubercle Bacilli in the Lesions of Phthisis," in the presence of the leading members of the profession of that metropolis. Neither the paper nor its discussion can be said to clear up all the uncertainty which must be admitted to hang about the question of the relation of the bacillus to the processes which previous to its discovery were commonly acknowledged to be phthisical, if not tubercular. At the same time, both have added facts which have an important bearing on the subject.

Dr. Kidd's paper is based upon a study of 80 cases, of which 75 were tuberculous, 2 sacculated bronchiectases, 2 malignant disease of the lung, and 1 dysenteric ulceration of the intestine. In the fetid contents of the bronchiectatic cavities were found numerous micrococci but no bacilli. Bacilli were invariably found in pulmonary cavities, and in nearly all cases in softening caseous material, provided that the morbid processes were associated with a tuberculous affection. Now, this statement would seem to imply that certain caseous processes were not associated with a tuberculous affection, while we are informed that all 75 were tuberculous affections. Dr. Kidd does not give his criteria of a tuberculous affection, nor whether he would consider the form of disease known as fibroid phthisis a "tubercular affection," although he says where fibroid induration was pronounced, no bacilli were found, showing that he included among the 75 cases some with fibroid induration. He also says that the distribution of the bacilli in the so-called caseous pneumonia appears to be very irregular. Thus, generally speaking, where the caseation was uniform and firm, no bacilli were found. But where the caseous process was commencing, or where softening was going on, and microscopical cavities were present, bacilli were often seen in great numbers; and the older the caseation the less the chances that bacilli would be present.

While there is no country in which the bacillus doctrine has received more general support than in England, it is plain, from the discussion which followed the reading of the paper, that English physicians are not all in accord on the subject. Some very interesting generalizations were however made. Dr. Creighton remarked that in the large class of cases included in the term granulomata, that is, leprosy, glanders, lupus and syphilis, rod-shaped bacteria not easily distinguishable, have been found. From this he deduces the fact that granulomata form a suitable nidus for the development of rod-shaped organisms. He was not satisfied that the connection between tuberculosis and the bacilli, to the exclusion of all other organisms, had been shown. Dr. Theodore Williams thought that Dr. Kidd's researches confirmed Koch's observations in every point.

Sir Andrew Clark, on the other hand, could not accept the statement that all the phenomena were to be accounted for by the tubercle bacillus, and thought such a theory at variance with clinical facts. If by phthisis was to be understood that assemblage and progression of symptoms associated with or dependent upon ulcerative or suppurative destruction of more or less circumscribed non-malignant deposits in the lung, then he was satisfied that there was a considerable number of cases within that definition in which no bacilli were found. In fibroid lungs with ulceration, bacilli could not be found either in the expectoration or in the tissues or cavities. He was not prepared to accept the view that organisms are always found in acute tuberculosis. In a considerable number of cases of caseous pneumonia, no bacilli are found until after softening has set in. In a few cases, on the other hand, they do occur, and this was to him a great difficulty in the way of accepting the theory of a causal relation. The life history of caseous pneumonia was so distinct from that of tubercular phthisis that the occurrence of the same bacillus in both forms of the disease tends to diminish the importance of the role played by that organism.

Dr. Green held that Dr. Kidd's paper is an addition to the ever-increasing accumulation of facts which tended to show that the bacillus was present in all those pulmonary lesions which were considered phthisical, and absent in others. Under the term

phthisis he included all cases of pulmonary disease which possessed (1) lung consolidation generally more or less apical; (2) lung consolidation which tended to undergo softening and disintegration; and (3) lung consolidation which possessed infective properties. From phthisis he would exclude chronic basic pneumonia, stone-mason's phthisis, etc., inflammatory disorganization from pressure on a bronchus, and syphilitic lesions.

Dr. Wilson Fox, whose comparatively recent retraction of his previous views upon tubercle—which were based on original experiments—added great weight to the bacillar doctrine, said that the old dicta about giant cells had passed away, and it is possible that even the bacillar doctrines may not be final. There is good evidence that tubercle is the only inoculable thing which produces tubercle, but it is a very grave step beyond that to say that phthisis is contagious. Dr. Reginald Thompson concluded that it is still questionable whether bacilli alone produce and propagate the disease. Dr. Moxon, on the other hand, had always felt a belief in the unity of phthisis, though he did not know its cause. Now the factor is revealed which makes phthisis one and the same thing. Dr. Moxon, too, makes the first suggestion we have yet met as to the duration of the existence of a tubercle, which is "probably three months, while that of a phthisical patient might be twenty years."

Dr. Watson Cheyne thought that bacilli might sometimes be overlooked in fibroid cases, while Dr. Heron declared they do occur in the sputum, and careful and systematic analysis discerns them sooner or later. Dr. Macnamara has failed to find the bacillus in the earlier stages of tubercular disease of bone, whereas in cases which have gone on to suppuration, the bacillus may generally be found, especially when there is a sinus communicating with the external air. He is, therefore, inclined to believe that tuberculosis of bone can originate without the presence of tubercle bacilli, and he does not consider the presence of air essential.

There is reason to believe from the above that we have been too hasty in discarding the definition of phthisis which was so generally received up to a couple of years before Koch's discovery was announced—the view which made several varieties of phthisis, of which but one was tubercular. It was the influence of the German school which shortly before Koch's discovery caused this view to be discarded and that to be substituted which made all phthisis tubercular. To us it would seem that Koch's discovery and its results tend to destroy the unity of phthisis, at least unless the clinical aspects of the disease are to be totally ignored, or until the bacillus is found in all the conditions clinically known as phthisis.

DISTAL LIGATURE FOR INNOMINATAL ANEURISM.

AT a recent meeting of the Royal Medical and Chirurgical Society, the proceedings of which are recorded in the *British Medical Journal* for January 31, 1885, MR. BARWELL read the particulars of the case of a woman forty-eight years of age, in which he successfully tied the carotid and subclavian arteries for aneurism of the innominate. At the expiration of five months the cure was found to be permanent, no enlargement could be detected at the original site of the tumor, percussion was clear, the respiratory murmur was distinct, and there was no pulse in any branch of the ligated vessels.

In the discussion which followed the reading of the paper, Mr. Holmes stated that simultaneous deligation was unnecessary. He preferred to tie the carotid first, as ligature of the subclavian might subsequently not be needed. In cases in which the stress of the aneurism falls chiefly on the subclavian part of the sac, it might be preferable to tie that vessel first; but, as a rule, ligation of the carotid completely arrests the current of blood, since it gives off no such considerable branches as does the subclavian. In addition to these points, he urged that ligature of the subclavian adds greatly to the danger of the operation.

It will thus be seen that the views of two of the most eminent authorities on aneurism at the root of the neck are in direct conflict. Hence, it may not be unprofitable to recall the statistics of the two operations, both as regards their direct results and ultimate effects, which we have endeavored to bring up to the present date.

The carotid and subclavian arteries have been tied for aneurism of the innominate alone at least 19 times, the operators having been Barwell in two cases, and Rossi, Lane, Holmes, McCarthy, Ensor, Elliot, Weir, King, Little, Stimson, Durham, Pollock, Browne, Cameron, Von Bergmann, Rosenstern, and Banks each once. Of the 19, 11 recovered, and 8, or 42.10 per cent., died as the direct result of the procedure. Of the 11 recoveries, 3 died, at intervals varying from fifty-five to one hundred and eleven days, from rupture of the sac; 2 died of phthisis at the expiration respectively, of twenty-two and forty months; 5 were living at the end, respectively, of three months, three months and a half, five months, ten months, and twenty months; and in 1 the exact date is unknown.

The carotid alone has been tied by Mott and Nussbaum each twice, and by Evans, Neumeister, Morrison, Scott, Dolhoff, Fergusson, Porta, Hutton, Vilardebo, Wright, Ordile, Broadbent, Butcher, Newton, Pirogoff, and Bryant each once. Of the 20, 5 recovered, and 15, or 75 per cent., perished. Of the 5 recoveries, the patient of Evans lived nearly forty years, 1 was living two months and a half subsequently, 1 died some time after of rupture

of the sac, 1 succumbed from asphyxia in seven months, and 1 perished suddenly in twenty months.

These data certainly do not sustain the views of Mr. Holmes. The immediate mortality of carotid ligature is greater by 33 per cent. than is that after ligature of both vessels, and it does not appear that the former operation is more important and influential in lengthening life than is the latter. Thus, there were only two permanent recoveries after carotid deligation, the cases being those of Morrison and Evans, whose patients lived respectively for twenty months and nearly forty years; while there were five final recoveries after ligature of the carotid and subclavian, namely, the two patients of Barwell, and the single cases of Cameron, Little, and Stimson, of which three were living, respectively, at the end of five, ten and twenty months, while the other two died of phthisis at the expiration, respectively, of twenty-two and forty months.

In the present state of our knowledge it may, therefore, be declared that the views of Mr. Barwell on the treatment of innominatal aneurism are entitled to greater confidence than are those of Mr. Holmes, since carotid deligation shows 33 per cent. more of deaths, and 16 per cent. less of final cures, than does simultaneous ligation of the carotid and subclavian.

THE PREVENTION OF INFECTIOUS AND CONTAGIOUS DISEASES IN SCHOOLS.

The Medical Officers of Schools Association, which was formed in England in 1884, has just issued a code of rules for the prevention of infectious and contagious diseases in schools, which contains some valuable suggestions, and which is important as being a formal expression of opinion on the part of medical men and sanitarians who have specially investigated the subject of school hygiene.

The first section relating to general hygiene gives the usual advice with regard to house-drainage, dust-bins, etc., and advises that the medical officer of the school shall inspect the premises at least once a month, and that he should make an annual return of the sickness in the school to the governing body.

With regard to the length of quarantine that should be required if a pupil has been exposed to an infectious disease, it is stated that this depends chiefly upon whether the school has or has not that very valuable safeguard—a disinfecting apparatus; which apparatus should be large enough to hold a full-sized mattress. If the school possess such an apparatus, then the quarantine should be a day or two more than the longest known period of incubation of the disease in question; if not, the period should be longer still, as there is no definite time when the clothing is certain to be free from infection.

The following quarantine times, after exposure to infection, are recommended as safe if thorough disinfection be carried out on the pupil's return to school:

Diphtheria	12 days' quarantine.
Scarlet fever	14 " "
Measles	16 " "
German measles	16 " "
Chickenpox	18 " "
Smallpox	24 " "
Mumps	24 " "
Whooping-cough	21 " "

Disinfection at home, it is urged, should not be relied on, but, immediately on the pupil's return to school, he should be washed with carbolic acid soap (ten per cent.) from head to foot, in a hot bath; and that clothes, books, and *everything* brought back by him, should be completely disinfected.

With regard to the question, "when may a pupil who has had an infectious disease go home or rejoin the school," the following are recommended as safe rules, viz.:

Scarlet fever—in not less than six weeks from the date of the rash, *if* desquamation have completely ceased, and there be no appearance of sore throat.

Measles—in not less than three weeks from the date of the rash, *if* all desquamation and cough have ceased.

German measles (Rötheln, or epidemic roseola)—in two or three weeks, the exact time depending upon the nature of the attack.

Smallpox and chickenpox—when every scab has fallen off.

Mumps—in four weeks from the commencement, *if* all swelling have subsided.

Whooping-cough—after six weeks from the commencement of the whooping, provided the characteristic spasmodic cough and the whooping have ceased; or earlier, *if* all cough have completely passed away.

Diphtheria—in not less than three weeks, when convalescence is completed—there being no longer any form of sore throat, or any kind of discharge from the throat, nose, eyes, ears, or other parts, and no albuminuria.

These rules are prepared more especially for the use of boarding-schools, but in most respects they are applicable to day-schools as well, and there can be little doubt of their good effects if properly carried out.

THE NATIONAL MEDICAL LIBRARY.

The condition and prospects of the legislation now pending in Congress for the providing a proper fire-proof building for the Army Medical Museum and Library are satisfactory.

On the 16th inst. the House passed a bill appropriating two hundred thousand dollars for such a building, to be constructed upon the Government

reservation, in the vicinity of the National Museum and Smithsonian Institution. To this the Senate will not agree, because it has taken the position that no more buildings shall be placed on Government reservations, but is willing to appropriate money to purchase a site—to which last proposition Messrs. Randall and Holman in the House will not agree. Meanwhile the Librarian of Congress and his friends, who want to sweep the Library of the Surgeon-General's Office into the proposed National Library, of which the said Librarian is to be in charge, are doing their best to prevent the reaching any common ground of agreement by the House and Senate.

In the debate in the House upon the passage of the bill it was opposed by Messrs. Potter and Nutting, of New York, on the ground that the books should be placed in the National Library. Mr. Potter objected on the ground that "this library and museum will end at last in a staff of officers to take care of it, and at the national expense, and an annual appropriation will be demanded to support and continue it for ever." And why not, Mr. Potter? Is there any other way of expending a similar amount of public money that will do one-tenth of the good to the people that the small annual appropriations for this library and museum have already done and will continue to do? In what way will there be any saving of expense by placing these books under the charge of the Librarian of Congress? Mr. Potter furthermore remarked that he "did not believe that we are to gain by preserving the relics and bones or wounds caused by the war, and that he wished they were all buried and hidden out of sight."

We presume that it is hardly necessary to explain to the readers of The News the short-sightedness of such a policy as this. Nothing will be saved by merging these collections with others. If it was only a question of four or five thousand volumes of books and a few hundred specimens, something might be said as to the economy of joining them with others—but when it comes to a hundred thousand volumes and a large anatomical and pathological museum, the case is altogether different. It will cost as much to care for them properly in a large building as in one devoted especially to them—nay, more, if the former is to be of marble and the latter of plain brick as proposed. This, however, is a consideration of very minor importance.

The merging of our great medical library, of which the medical profession of this country are now so justly proud, and in which they are so deeply interested, would be a calamity which we should endeavor to avert in every possible way. The utility and prosperity of the National Medical Library and Museum depend largely upon their being kept together, and preserving their individuality under skilled management. No greater mistake could be made by Congress than to destroy this individuality, and with it the strong helpful interest now taken in these institutions by the profession. This is one of the points upon which all medical men are agreed, and we do not doubt that they will at once exert both their individual and collective influence to prevent the carrying out of such a scheme.

If the bill to provide a plain but commodious fireproof building for our National Medical Museum and Library fails this session, it will be due to a few ambitious, selfish men who would ruin what they cannot rule, and the physicians of this country must see to it that the members of the next Congress are so instructed that there shall be no possibility of failure next time.

Meanwhile, we still hope that the present Congress will do its duty in the matter, which is one of the greatest possible importance to medical education and medical science, and, therefore, to all who have need of the services of skilled physicians.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, February 19, 1885.

The President, A. Jacobi, M.D., in the Chair.

Dr. Gaspar Griswold read a paper on

ELECTRICITY AS A STIMULANT IN CARDIAC AND RESPIRATORY FAILURE.

Electricity, he said, has long been conspicuous among the agents that are resorted to for the relief of sudden prostration attended with cardiac and respiratory failure, such as is apt to occur from the use of such poisonous drugs as opium and chloroform; and the object of the paper was to inquire how far the methods employed were in accordance with what is known in regard to the physiology of the heart's action. Having referred briefly to the effects of the two currents, the galvanic and the faradic, he proceeded to ask, Can electricity be so applied as to stimulate the heart directly? In order to decide this, he said it was necessary to glance at the mechanism of the heart's action; and in doing this, he referred particularly to the retarding effect exerted by the pneumogastrics as opposed by the action of the accelerators of the heart. The action of the pneumogastrics was always inhibitory, while the accelerator nerves increase the rate of the cardiac pulsations at the expense of force. It was evident, therefore, that in order to stimulate the heart it would be necessary to apply the electricity to the organ itself. As a matter of fact, however, it was found that when one or both electrodes were placed over the præcordial region, the heart-beat was retarded. In order to illustrate the effect of doing this, he would refer to two cases. The first, reported in the *Philadelphia Medical Times* of June 4, 1881, was one of death from cardiac failure after etherization. The pulse was feeble and beating 180 to 200 per minute, while the respirations were quiet and regular, numbering about 22. Hypodermic injec-

tions of tincture of digitalis and whiskey, and of digitalis and sulphate of atropia were given, in addition to an enema of whiskey. "Then," the account goes on to say, "the faradic battery, which had been brought to the bedside, was suggested as a remedial agent, but as the respiration was continuing comparatively unaffected, it was only applied for a short time, with one pole to the neck, and the other in the præcordial region." The patient continued to sink, notwithstanding the further injection of the remedies mentioned, and died a little more than an hour after the anæsthetic was withdrawn. The idea here, said Dr. Griswold, was to stimulate the heart; but the reverse effect was noticed, and the use of the battery might readily have caused the patient's death.

The second case, reported in the *British Medical Journal* of July 2, 1881, was one of poisoning by bitter almonds. When seen, the patient was quite insensible and collapsed; breathing gasping and labored; he was cyanotic; the pulse was hardly perceptible, rapid and flickering, and the heart's apex-beat weak and rapid. The stomach-pump was at once used, and the stomach was then washed out with warm water, after which the patient became more collapsed, and his radial pulse almost ceased. The battery was now used for ten minutes—one pole over the apex of the heart, the other on his neck, over the course of the pneumogastric nerve. In twenty minutes, liquor ammoniæ fortior was given as an inhalation, and the current from twenty-five cells of Leclanché's battery applied as before, contact being made and broken with the inspirations. The battery and ammonia inhalations were then continued alternately, at first every ten minutes, and afterwards every half hour, for about four hours. The patient recovered, and this was attributed mainly to the employment of the electricity. It was a fact, however, that the current from a battery of twenty-five cells applied to the pneumogastric would kill a large dog, and that that from six cells would cause faintness in human beings; and therefore this treatment was improper. The recovery might be explained on one of two suppositions: either the battery was out of order, as batteries are very apt to be when called into sudden requisition, or else the pneumogastric had already become paralyzed, paralysis of this nerve being one of the results of hydrocyanic acid poisoning. It was stated in the report that the bitter almonds were eaten three hours before the electricity was applied, which would have given time for this effect to be produced. The application of electricity in this way was, then, the reverse of stimulating in its effect upon the heart, and involved great danger to life if a strong current was employed.

In regard to the respiratory function, he said that the stimulation of the phrenic nerve caused contraction of the diaphragm, and it was perfectly rational, therefore, to apply electricity to the neck for the purpose of counteracting respiratory failure. This might be done in two ways, either by applying a mild current continuously, or by employing one of sufficient strength to excite at once a deep inspiration, and repeating it at intervals of three or four minutes. Good results had been reported from its use in this way in opium poisoning, but the effect was always due to the stimulation of the phrenic nerve alone. Theoretically it was impossible to apply a current to the phrenic without affecting the pneumogastric also, because they lay so close to each other in the neck. The function of the pneumogastric was to retard or even stop the heart's action; but as in opium poisoning this nerve was apt to be paralyzed, electricity could be applied to the neck in this condition with a prospect of its affecting only the phrenic nerve. He knew of one case of opium poisoning, however, in which instant death was produced by the sudden application of a current in this locality for the purpose of stimulating the phrenic, through the effect that it had upon the pneumogastric. The conclusions which he derived from the foregoing considerations were: 1. That electrical stimulation of the phrenic nerve is liable to stimulate the pneumogastric also; 2. That only mild currents should be employed; and, 3. That especially should the sudden application of a strong current in the neck be avoided.

The circumstances under which his attention was first directed to this subject were the following: A patient that he was attending got an overdose of tincture of aconite root through the druggist's mistake in neglecting to add the water in a prescription which he had ordered containing this drug. The application of electricity to the neck, on account of the embarrassment of respiration present, was advised by Prof. A. A. Smith, who was called in consultation; but Dr. Griswold opposed this on account of the bad effect it might have on the heart's action through the stimulation of the pneumogastric nerve in addition to the phrenic. On account of the interest in the matter which this case excited, he determined to make some investigations himself, and, therefore, performed a series of experiments on dogs. He first applied a faradic current to the pneumogastric, and found that it appreciably slowed the action of the heart, as indicated by a Marey's cardiometer inserted into the carotid. The animal's system was then brought under the influence of aconite; when it was found that no effect whatever was produced upon the heart by the same strength of current. Even when the current was increased to the full strength, there was still no effect; the explanation being that the pneumogastric was paralyzed by the drug. He did not wish to claim any originality for this experiment, which he repeated with two other dogs, as it had been performed by others previously; but he was glad to know that the results which he obtained were corroborated by the observations of other investigators. The deduction that he drew from it was that there is no danger from electricity in aconite poisoning, and it is, therefore, perfectly safe to apply it to the phrenic nerve. Consequently he believed that Prof. Smith had been right in advising its use in the case to which he had referred.

The next experiments were with dogs under the influence of chloroform. A faradic current was applied to the pneumogastric, and the effect was instantaneous. In one case the heart stopped in diastole, and did not beat again, and while death occurred less promptly in the others, the result was the same. Deduction: The pneumogastric retains its excitability in chloroform poisoning, and it is, therefore, extremely dangerous to apply electricity to the neck in this condition. In asphyxiation by ether, he found that the heart could stand stimulation of the pneumogastric as well as in health, and he concluded, therefore, that it was safe to stimulate the phrenic nerve to a certain extent in this

condition. Chloroform was a direct cardiac depressant, while ether was not. In opium poisoning, when well marked, the pneumogastric was paralyzed, and there was, therefore, less danger in stimulating that nerve in this condition than in health. When morphia was injected into a vein, however, he found that the case was different, and the deduction that he made from this experiment was that when morphia is injected into a vein, the heart is easily depressed by the application of electricity to the pneumogastric.

His general conclusions were as follows:

First. Electricity cannot be applied clinically in such a way as to stimulate the heart, literally speaking.

Second. The application of one pole of the battery to the neck and the other over the præcordial region, when the pneumogastric is not paralyzed, may result in death.

Third. The stimulation of the phrenic nerve also stimulates the pneumogastric, on account of the proximity of the two nerves.

Fourth. The liability to depress the heart from stimulation of the pneumogastric in connection with the phrenic is not great in aconite, ether, or opium poisoning, on account of the paralysis of the pneumogastric produced by these drugs.

Fifth. In heart-failure from chloroform, and the injection of morphia into a vein, the application of electricity to the neck is strongly contraindicated.

Sixth. Under no circumstances should a current strong enough to cause muscular contraction be applied suddenly to the neck.

DR. A. D. ROCKWELL remarked that what he should have to say would be, in the main, confirmatory of the views expressed by the author of the paper. Electricity had long been recognized as of special value in stimulating the respiratory function, rather than the action of the heart. A few years ago it had been claimed by certain authorities that the action of the two pneumogastric nerves, on the two sides of the body, was somewhat different in character; the one affecting the respiration more, and the other the cardiac functions. Clinical observation in the use of electricity, it seemed to him, had afforded a considerable amount of corroborative evidence of the correctness of this hypothesis. One of the most important things about the action of electricity, and one which was apparently very imperfectly understood by medical men, as a rule, was its secondary influence. As one who had paid much attention to the subject of electro-therapeutics, he fully appreciated the force of the statements made by Dr. Griswold. Theoretically. his views were undoubtedly sound; but, as a matter of fact, he did not believe it was necessary to use electricity with such extreme caution as had been advocated in the paper. Some time ago, Brown-Séquard, Anstie, and others, had laid stress upon the great danger of applying electrical currents to the central nervous system through the pneumogastrics. He could easily understand why such unpleasant results as they mentioned might be apprehended, reasoning from the physiological functions of the pneumogastric; but, practically, he did not believe the application was so dangerous as was inferred. In this connection he related a case he had seen two years ago, in which he was called to attend a patient who was in an unconscious condition from some narcotic poison, afterwards ascertained to be opium. When first seen, the respirations were about ten to the minute, and the pulse about forty. The application of the faradic current to the phrenic nerve in the neck had a very striking effect, and immediately the respirations went up to normal. The pulse also rose under the action of the electricity, and for two hours the application was kept up intermittingly. At the end of two hours, however, both the pulse and the respiration began gradually to decline, notwithstanding the continued use of the agent, and after four hours of treatment the patient seemed to be in exactly the same condition as when first seen. Under these circumstances the case was believed to be utterly hopeless, and further treatment was abandoned; but, strangely enough, reaction set in after a time spontaneously, and the patient recovered. The practical lesson to be derived from this case was, he thought, that as long as there was any breath at all left in a patient's body, the use of electricity should be kept up. Here undoubtedly the employment of the current for four hours had tided over the system under the depressing influence of the opium until nature had a chance to assert her powers.

DR. FORDYCE BARKER remarked that there were two or three collateral points of practical interest in connection with the paper upon which he should like to say a few words. One was the comparative influence of ether and chloroform on the heart, and he thought there were certain clinical facts bearing on this which would seem to militate against what might be inferred from the paper. In obstetrics he had found that chloroform had a very different effect from that which it had when given as an anæsthetic in surgical practice, and in a paper which he had written many years ago, he had expressed the opinion that ether was much the safer agent to use in general surgery, and chloroform the safer in obstetrical cases. The reason that he assigned for this was that in surgical practice the anæsthetic was given to anticipate suffering, while in the case of the parturient woman it was used for the relief of pain already existing. Under the latter circumstances, he believed the system would tolerate the depressing influence of a drug which it might not in ordinary conditions.

It had long been an accepted point in the opinion of the profession that it was unsafe to administer an anæsthetic when there was organic disease of the heart; but it was, at least, twenty-five years since he had ceased to believe that the existence of such disease was a contraindication against the use of chloroform in pregnant women. On the contrary, the presence of cardiac trouble was to him an indication which induced him to resort to this anæsthetic at an earlier period than usual. Ether, however, was not safe, and its use in such cases was to be condemned. That chloroform was a protection rather than a dangerous or injurious agent, under the circumstances, was strikingly shown in the case of a patient in the lying-in wards of Bellevue Hospital, which he had seen many years ago. When this woman came into the wards, expecting to be confined, she was found to be in the advanced stages of valvular disease of the heart, with marked dropsy, dyspnœa, etc., and her case was watched with much interest. One night he was summoned hastily to the hospital by the *interne*, as labor had commenced, and she was in such an alarming condition that fears were entertained that she would not survive delivery. She was suffering

from great depression of the vital forces, and at every pain the pulse would fail entirely. Under these circumstances, he concluded to try the effect of chloroform, and immediately the patient's suffering was completely relieved. The administration of this was kept up for some time, and while the patient remained perfectly comfortable, the uterine contractions went on in a very satisfactory way. The pulse and the whole condition steadily improved under its use, and the delivery was accomplished without difficulty; the uterus also contracting well afterwards. She rapidly improved after her labor, and when she left the hospital her friends remarked that she was looking better than she had for a long time previously. During pregnancy he believed that there was a normal physiological hypertrophy of the heart, and at the time of parturition he thought there was a saving of vital or nerve power secured by the administration of chloroform, which more than counterbalanced any tendency on the part of the drug to produce failure of the heart. That the same thing would be true in case of ether being substituted for chloroform, he did not believe; and he would repeat, therefore, that obstetricians should never use any other anæsthetic than chloroform. Within the past two years, a physician in Edinburgh, whose name he could not just now recall, had written a book in which very much the same views as his own in regard to the position of chloroform in midwifery practice were expressed.

Dr. R. W. Amidon said that he agreed fully with the opinions expressed in the paper, but regretted that its author had not pointed out what remedies could be depended upon to take the place of electricity, which he had so admirably shown did not deserve the position in the class of cases referred to which it had hitherto held in the opinion of the profession. He could see why Dr. Rockwell, who is a specialist, and therefore exceedingly skilful in the application of electricity, should take a somewhat different view of the safety of the agent from that entertained by the reader of the paper, who is a general practitioner; but in the pressing circumstances of the emergency, in which physicians were ordinarily called upon to treat a case of opium, ether, or chloroform narcosis, for instance, the chances were that the electricity would by no means be applied in an efficient or judicious manner. It is not a simple, but a powerful and dangerous remedy, which comparatively few medical men know how to use intelligently. On the other hand, artificial respiration is a means of treatment which all can employ without danger of doing any harm, and which is very likely to be followed by good results in all cases of respiratory failure; while it is a fact which ought not to be forgotten, that in many cases the cardiac failure is secondary to this.

Dr. L. Putzel was of the opinion that, while the physiological aspects of the subject were well stated in the paper, the deductions from experiments on animals were not trustworthy. In the human subject no method had yet been devised for applying electricity directly to the pneumogastric nerves; so that the best electrotherapeutists spoke now simply of galvanization of the neck. With regard to the evil effects of the application of a strong current to the neck, he thought these had been exaggerated in the paper, since he himself had frequently used a current from a twenty-five cell battery, in perfect order, in this situation, and was still constantly doing so in cases of exophthalmic goitre, without producing any appreciable effect upon the heart or respiration. From a clinical standpoint, the subject is one which he thought needed revision. As had been well said, physicians are apt to be extremely careless in this matter, and in the report of a case it would not do simply to state that electricity was applied.

Dr. J. Leonard Corning said he must take exception to the statement made by the last speaker, that it was impossible to apply faradization to the pneumogastric nerves, and proceeded to describe a method of his own by which he claimed to have successfully done this. This, he believed, was proven by the effects produced, and he said that in a case of exophthalmic goitre he had reduced a pulse of 140 to 80 within a period of three months.

Dr. Andrew H. Smith remarked that in opium poisoning the great difficulty was usually in the respiratory function, and therefore the principal object was to stimulate the failing respiration. The fact could not be denied that it was usually possible to produce a full respiration by the application of electricity to the phrenic nerve; and if this was repeated about sixteen times a minute, it was apt to be followed by good results. It should not be done oftener than this, though there was a strong temptation to push the application; and in this way the cardiac failure might be secondarily arrested. Electricity was also useful as a general stimulant in opium poisoning. Flagellation was often injudiciously practised, and from the abuse of this there was liable to arise the added danger of shock.

Dr. Putzel explained that he did not wish to be understood to say that galvanization of the neck *never* slowed the pulse, but that in his own experience he had never observed this effect.

The President said that in former years he had used electricity a great deal in cases of cardiac and respiratory failure, such as was seen in opium poisoning, but more especially in the asphyxia of the newly born. He had found that if the current is used more or less continuously for any length of time, while at first these functions are stimulated, the increased activity is afterwards followed by paralysis; and that this effect is reached the more speedily the closer to the phrenic and pneumogastric nerves he applies the electricity. This experience taught him, therefore, that the best practical way of using the agent is not to confine the current to the nerves, but to apply it generally to the muscles. His method is to keep one electrode on the body and then bring the other in contact with the skin in a succession of quick applications to the various parts of the surface, and this is the plan that he would advise in cases of opium poisoning. The shock thus received is often sufficient to excite the respiratory function, and he quite agreed with Dr. Amidon that the failure of the heart is often secondary to that of the respiration. The electrode used for those general applications upon the surface should preferably be a faradic brush.

Dr. Griswold said that in his paper he had dwelt upon three points. The first was that the heart cannot be reached in such a way as to be stimulated efficiently and certainly. He would not have thought it necessary

to lay any stress upon this had not the two cases to which he had referred at the outset, published in medical journals of high reputation, led him to believe that such an opinion might be entertained by a certain number of physicians. The second point was to call attention to the fact that the pneumogastric and phrenic nerves lay so closely together in the neck that the stimulation of one was impossible without that of the other in addition. In opium poisoning, where the patient was well narcotized and the heart's action had become frequent, we could stimulate the pneumogastrics with impunity, on account of their state of paralysis. In the case of instant death to which he had referred (of which he had learned from Dr. Janeway, who had expected to be present and speak more particularly of it), the pneumogastric had not yet become completely paralyzed at the time the current was suddenly applied to it. It was, therefore, confirmatory of the results shown by his own experiments on dogs; so that he believed that the reason why more patients suffering from opium poisoning were not killed by the application of strong currents to the neck was on account of the complete paralysis of the pneumogastric. The only point that his experiments bore on, he continued, was the exaggerated sensibility of the heart to the action of electricity. In chloroform poisoning particularly, he believed it was best to rely on artificial respiration, which was safe and efficient, while stimulation of the phrenic nerve was not safe or efficient. The hypodermic injection of ammonia, alcoholic stimulus, etc., might also be employed. In regard to chloroform, Simpson was the first to show that it was much more of a local anæsthetic than other drugs of its class. The local effect of ether was simply one of freezing, on account of its rapid evaporation.

Dr. M. Josiah Roberts gave a description and practical

DEMONSTRATION OF THE WORKING OF ROBERTS'S IMPROVED ELECTRO-OSTEOTOME; A NEW FORM OF PORTABLE STORAGE BATTERY AND AN ELECTRICAL ILLUMINATING APPARATUS.

The osteotome is an improved form of the one described in the *New York Medical Record* for October 20, 1883, and consists of an electro-motor with a central shaft, to the extremity of which saws of various sizes can be attached. It is claimed that perfect accuracy of cut can be secured with the instrument. Five seconds are required to saw through an adult femur, and Dr. Roberts stated that in his largest osteotomy at one sitting he had made six sections of bone in thirty seconds. A drill can be substituted for the saw, and by this means exploratory punctures can be made into the heads of bones, answering to exploratory punctures of soft parts with the hypodermic needle. The apparatus is also provided with an electric light, which can be used when necessary; two cells of the battery being reserved for the purpose of maintaining it. Metallic retractors are employed for the purpose of protecting the soft parts while the osteotome is in operation. The improvement is the increased oxidation on the surface of the leaden plates used, and Dr. Roberts claims that it can be implicitly relied upon for all practical demands.

NEW YORK COUNTY MEDICAL ASSOCIATION.

Stated Meeting, February 16, 1885.

The President, Charles A. Leale, M.D., in the Chair.

Dr. Theodore R. Varick, Surgeon-General of the State of New Jersey, read a paper on

THE PROTECTIVE TREATMENT OF OPEN WOUNDS.

However different his views may be from those entertained by a large number of surgeons, he said, they are not the inspiration of a moment, but the conviction of long-protracted observation. In grave surgical injuries the sources of trouble were, first, from shock and hemorrhage; and, secondly, from sepsis; and from time immemorial it had been the aim of surgeons to minimize the dangers of the former, and prevent the occurrence of the latter. In order to accomplish this latter end, it was desirable to protect the parts as perfectly as possible from external influences, and any method by which they could be hermetically sealed, and yet which would not result in causing irritation of the tissues beneath, would certainly be a great desideratum. In order for the production of sepsis, a solution of continuity was necessary. At first the danger was warded off by the constant exudation from the vessels of the injured parts. When this ceased, the open stomata of the vessels afforded a ready avenue for the absorption of septic material, unless something was done in the meanwhile to close or cover them.

Having read the description given by Sir James Paget in Holmes's *Surgery* of the appearances presented by open wounds, he made the following quotations from Flint's *Physiology* in regard to blood-serum: "The serum contains all the elements of the blood, except the red corpuscles and fibrin, which, together, form the clot." "It contains all the principles found in the plasma, or liquor sanguinis, with the exception of the fibrin. It can hardly be called a physiological fluid, as it is formed only after coagulation of the blood, and never exists isolated in the body." Blood-serum is largely albuminous, and it was this element, Dr. Varick continued, which he had to consider. On the coagulation of the albumen depended the success of the method of treatment of open wounds which he advocated; and since he had adopted this plan, he had yet to meet with the first case of septicæmia in his practice.

It was, indeed, to their property of coagulating this element that the bichloride of mercury and carbolic acid owed their reputation as antiseptics in surgery; but there were positive objections to both these agents, which, in his opinion, rendered them, as a rule, entirely unsafe to use. In regard to the bichloride, there was a possibility of constitutional effects resulting from its use, and several cases had already been reported in which severe tenesmus had been caused by it. Another objection to it was its irritant effect locally, and in this connection he quoted from an address made by Sir Joseph Lister at the opening meeting of the Medical Society of London October 20, 1884, in regard to the case of a lady from whom he removed the mamma and cleared out the axillary glands, as follows: "I put immediately over the wound a piece of prepared oiled silk, which I dipped in a 1 to 500 solution of corrosive sublimate; then, over this, sublimate gauze, and outside

all, abundant eucalyptus dressing. On the following day, when we changed the dressing, I found that under the oiled silk, exactly corresponding to this extent, the skin was highly irritated, and was covered with small vesicles. I also found that the inner side of the arm, where there was no wound, was in the same state of intense irritation. . . . . While this case showed that in the sublimate we had an agent that might give very beautiful results, it also indicated that we were dealing with an edged tool, which, while it might do admirable work, was very apt to cut our fingers."

In speaking of carbolic acid, he quoted Bartholow (*Materia Medica and Therapeutics*) as follows: "Applied to the external integument, carbolic acid is absorbed and systemic effects follow, the urine becoming smoky. Fatal poisoning has resulted from such applications (Köhler)." In a case of Dr. H. B. Sands, of New York, in which the patient had been subjected to the operation of amputation of the thigh for ununited fracture of the femur, for five days after the operation the urine was green in color; an effect due to the absorption by the wound of carbolic acid, and in accordance with the antiseptic method of operating (*New York Medical Record*, vol. xx. p. 151). Mr. A. Pearce Gould had reported at the Clinical Society of London, in 1879 (*Lancet*, April 26 and May 17, 1879), a case of amputation at the hip-joint, in which the patient died at the end of sixty-eight hours. At the autopsy all the veins of the left foot, leg, and thigh, were found to be filled with black coagulum, which reached into the common iliac vein; the thrombosis being due to carbolic acid poisoning. All went well up to forty hours after the operation, when suddenly and coincidently with the excretion of carbolic acid urine, the fatal symptoms set in—symptoms which were not merely local and limited to the affected limb, but general. Dr. Varick then referred to a large number of other cases in which fatal or dangerous results had followed the local use of carbolic acid, reported by both American and foreign writers. Among the former was Dr. Alfred C. Post, who reported at the New York Pathological Society, March 26, 1879, a case in which death was only averted with the greatest difficulty. A subacute abscess in the gluteal region, connected with old disease of the hip-joint, in a child five years of age, was evacuated, and the cavity injected with a solution of carbolic acid, according to the method advised by Callender; when in a few hours the patient presented the constitutional symptoms of profound carbolic acid poisoning. In an almost precisely similar case reported at a meeting of the Boston Society for Medical Improvement, held March 28, 1881, by Dr. S. H. Bradford, the patient died. The abscess contained about eight ounces of sero-purulent fluid. Carbolic spray was played upon the limb during the incision; the abscess was hyperdistended with a solution of carbolic acid of a strength of one to forty. The patient recovered quickly from the ether, but in the following night was seized with obstinate vomiting, which persisted during the morning, but stopped at noon. It returned again in the night, and the following morning the child was in a feeble condition. The urine that was passed was tar-colored, and death took place two days later, with symptoms of collapse. Having referred to some experiments on turtles and frogs, by Dr. H. G. Byer, U. S. N., which showed in a striking manner the depressing effects of carbolic acid, he said, in summing up, that both carbolic acid and bichloride of mercury were undoubtedly liable to excite toxic effects, and were therefore unsafe.

What method are we to adopt, then, in the treatment of wounds, he asked. For six years, he said, it had been his practice to use *hot water*, slightly below the boiling point, freely and continuously, until all oozing had ceased. The effect of this was to cause the formation of a protective shield from fibrogenous material which was always available. This procedure, he claimed, not only facilitated healing, but also tended to prevent shock. By the transmission of heat it assisted in strengthening the heart's action, and he had had no death from either primary or secondary shock in his public or private practice since he had adopted it, although his hospital experience had been very large. The method presented the following merits: 1. Simplicity; 2. Availability; 3. Safety; 4. Invulnerability.

In order to test the protective agency of albumen, he had performed a number of practical experiments. Among them were the following: On the 13th of October, 1884, he had taken twelve test-tubes, and, having thoroughly cleansed them, partially filled them with freshly prepared beef-tea. He then divided them into two sets. Over the mouths of five of the first six he placed linen covers coated with serum, leaving the sixth uncovered, while five of the other six were also covered, but with material that was not coated with serum. Within twenty-four hours the beef-tea in three of the second set of tubes was milky and turbid, and within forty-eight hours, the contents of the remaining three were manifestly undergoing decomposition. At the present date, four months after the serum-coated coverings had been applied, the beef-tea in all the test-tubes treated in this way was found to be as clear and fresh-looking as on the day on which it was put into them. (The test-tubes were handed round for the inspection of the members.)

He had commenced a second series of experiments on January 21, 1885, preparing seven test-tubes in the same manner as before, and covering six of them with linen coated with serum, but leaving the remaining one open. Within twenty-four hours the beef-tea in the latter was loaded with bacteria, and decomposition was advancing rapidly; but the contents of all the other tubes still remained in a perfect state of preservation. This paper, Dr. Varick remarked, in conclusion, was intended to be supplementary to one which he read in May, 1884, before the Surgical Section of the American Medical Association, on "Railroad Injuries of the Extremities, with Observations on the Site of Amputation and Subsequent Treatment of the Stump."

DR. WILLIAM DETMOLD said that he had been the more interested in the paper from the fact that the practice therein advocated had been the one which he had himself pursued throughout his whole professional career, with the exception that he had not employed the water hot, like Dr. Varick. He had never yet been converted to the germ theory, and had always condemned the use of carbolic acid and other so-called antiseptics. He had been accustomed to using simply a compress with even the largest wound. The hot water might perhaps be an advantage, but he thought that Dr. Varick had not demonstrated the fact that the water he employed

was hot enough to coagulate albumen. He did not feel certain that the albumen would not coagulate, or rather become dry, without heat in the case of wounds. In private practice, he had never seen any sepsis in connection with the latter, except in certain localities, generally the scrotum or some other part of the genito-urinary tract. What was it, he asked, that made internal urethrotomy so dangerous? A great many cases of this proved fatal, while such a result was very rare in external urethrotomy, in which we would naturally expect to find it most frequent, according to the hypothesis of atmospheric germs, on account of the free access of air to the parts. In internal urethrotomy, this was not the case; but the cutting was done in a situation where the cellular tissue was loose and the large vessels did not contract readily. He thought pus got into the veins without the agency of any germs.

In regard to water dressing for wounds, he believed that the use of even cold water might be carried to a degree that was injurious, and he had seen it almost macerate the skin. It was his custom to apply compresses now that were wrung out, so as not to drip, and in this way the possibility of macerating the epidermis was obviated. Notwithstanding the prevalence of the new fashion of antiseptics and drainage-tubes, he had always adhered to the old methods. He had been brought up to consider that in surgical practice foreign bodies should always be removed, and he did not like the idea of introducing additional foreign substances into the tissues. In regard to Dr. Varick's experiments, he thought it had not been proven by them that blood-serum, without being exposed to heat, would not have the same effect as the serum after having been thus exposed to heat; and it was his opinion that it had.

DR. VARICK said that he did not know that he was fully prepared to answer Dr. Detmold's objection. Physiologists tell us that albumen outside of the body remains fluid until it is subjected to heat or some chemical agent, having the power of coagulating it. When it is exposed without the influence of these agencies, the process which it undergoes is simply one of desiccation rather than coagulation. If there is anything in the germ theory (according to which sepsis is caused by the admission of foreign disease-bearing organisms), during the time required for the albumen to desiccate there was ample opportunity for the introduction of such germs; but if measures are taken to secure the prompt coagulation of the albumen, before the outward flow from the vessels of the injured part had ceased, such an occurrence is rendered impossible.

DR. J. W. S. GOULEY remarked that there were several points of great interest touched upon in the paper, but he would refer to only one or two of them. In regard to the treatment of wounds, it had long been agreed upon by all surgeons that, whether from fear of contamination of the injured parts or to facilitate more prompt union, it was desirable to bring about coagulation of the serum effused. Years ago, it had been his custom to apply to the surfaces of all wounds a solution of chloride of zinc, prepared in accordance with the formula of Dr. Pancoast, of Philadelphia; the object being to accomplish exactly the thing which Dr. Varick now succeeded in doing by much simpler means. With the idea of obtaining as thorough coagulation as possible, he had always waited for an hour or more before closing the wound; by which time he found that it was usually completely glazed. He had met with a certain proportion of cases of septicæmia; and in his experience profuse hemorrhage was more apt to be followed by pyæmia than any other accident or condition. Like Dr. Detmold, he was not yet a convert to the germ theory, and it seemed to him that excessive loss of blood was a much more probable factor in the causation of septic trouble than the admission of any so-called germs. He differed from Dr. Detmold, however, in believing that the pus did not enter the veins from without, but was really formed in them. When a thrombus had occurred, it was liable to undergo disintegration, and thus it was that suppuration took place in the liver and other parts. He had seen patients die, not from hemorrhage, but from the putrescent condition of the injured part, within forty-eight hours, or, in other words, before any germs could have had time to undergo their process of development, and bring about a fatal result.

But as he had said before, he had long been a believer in the prompt coagulation of the surfaces of wounds, and he could not too strongly express his obligations to Dr. Varick for the bold stand which he had taken in condemning the use of such agents as carbolic acid and the bichloride of mercury. He believed that more lives had been lost through the agency of carbolic acid than could possibly have been saved by it. The surgeon himself was sometimes the victim of the poison, and Dr. Donald Maclean, Professor of Surgery at Ann Arbor, had once suffered from bloody urine, and was really quite ill for several days after performing an operation in which the carbolic spray was used. All good surgeons, indeed, were antiseptists, but were not all Listerists. The first case of pyæmia resulting from profuse hemorrhage, which he had seen, was that of a robust young man, who had received a severe gunshot wound of the shoulder. He lost a very large quantity of blood, and, after a few days, chills set in, and he died from pyæmia resulting from thrombosis. In a large number of autopsies Dr. Janeway had found thrombi in the veins of the pelvic and other regions.

DR. C. S. WOOD, who was introduced by the Chair as having been one of the surgeons at Gettysburg, said that during the last few years the subject of antiseptics had undergone many changes, and that he believed that many of our best authorities at the present day were inclined to lay aside this bactero-mania which had been so prevalent. At the time of his experience in the army Listerism was not known, and while gangrene and sloughing were seen arising from special causes, he did not believe that these complications were due to the lack of antiseptic precautions. Among these special causes were all kinds of depressing influences. After the battle of Gettysburg more than eleven thousand wounded soldiers, both Union and Confederate, were under the care of our surgeons. The circumstances surrounding both classes were precisely alike, the surgeons making no difference whatever in the degree of care with which they attended to their injuries, yet on account of the feeling of elation after victory on the one side and of depression resulting from defeat on the other, a much larger proportion of Union soldiers recovered than of the Confederates. Again, at Fair Oaks, the next day after wounds had been received or

amputations performed, the seat of injury or stump was found to be covered with maggots of enormous size, and the terror which the men felt at the idea of having living animals thus crawling in and out of them had such a bad effect that the proportion of fatal cases was unusually large. When it had been discovered that the use of turpentine afforded an efficient means of getting rid of the maggots, the results were much more favorable; and it was also found that in the cases in which turpentine was employed, gangrene and sloughing were exceedingly rare. The effect of the weather on patients suffering from wounds was also well shown during the war. After all great battles a storm was sure to follow, to which the wounded were usually exposed with very little protection, and it was found that if the storm continued but for one day, it was decidedly beneficial in its effect, cleanliness being, as he believed, the essence of antisepsis; but if it lasted for two or three days, the results were injurious, on account of the men having to remain wet for so long.

Dr. Detmold said that he could confirm what Dr. Wood had mentioned in regard to maggots from his experience in European hospitals. Patients were usually greatly disgusted with them; though it had been demonstrated that in reality they were utterly harmless, being simply the eggs of the fly unusually developed by heat and moisture. The moral effect of their presence, however, was exceedingly bad.

The President thought that the microscope would explain one of the questions raised, and also explain the wonderful success of Dr. Varick. It was found that the blood-corpuscles became swollen from endosmosis, and that their decomposition afterwards resulted. Water at ordinary temperatures did not possess the power of coagulating fibrin, but hot water had that power. By the agency of the latter a film was formed that coated the wound and prevented both the decomposition of blood-corpuscles and the entrance of any germs from the atmosphere, granting that these were sometimes the cause of sepsis. Dr. Varick's experience had been unusually great, as he had long been connected with two of the largest hospitals in the United States, in which an immense number of acute surgical cases was treated all the time.

Dr. Varick, in closing the discussion, remarked that he had little to say in addition to his previous statements. In the paper that he had read, the results which he had met with had been alluded to only in a general way. The statistics of his amputations were fully set forth in the other paper mentioned, which he read at the last meeting of the American Medical Association. They were all major operations, and mostly in cases of railroad injuries. He had also had some major amputations since that paper was prepared, and he would now refer for a moment to these, in connection with the others. From the middle of August, 1879, up to the date of the paper, he had had at St. Francis Hospital, Jersey City, 21 such operations, and since then 1 primary amputation of the arm; making 22 in all, all of which were successful. At the Jersey City Hospital, during the period named, he had had 7 operations, and since then 4; making 11 in all, of which 1 case proved fatal. This amputation was of the thigh, and the patient, who was a broken-down tramp, died in the night from secondary hemorrhage. In private practice, he had had up to the date of the paper 3 cases, and since then 1. Of these 4, 1 died; but the stump was doing perfectly well, and the real cause of death was valvular disease of the heart. There was thus a total of 37 cases, with 2 deaths; which, he thought, was a pretty good showing for the method of treatment adopted. His success depended also on two other additional points, viz.: making the amputation through sound tissue, and keeping the stump clean.

That the hot water treatment did exert a protective power against hospitalism, he had met with several excellent illustrations in his experience. On one occasion, at the Jersey City Hospital, when the house was greatly crowded, and when there were several cases of puerperal fever in the obstetric wards and nine or ten cases of erysipelas in the male wards, two cases of railroad injury were brought in which involved amputation of the thigh. Yet both these patients made good recoveries, notwithstanding the exceedingly unfavorable influences to which they were subjected.

Referring to Listerism, he said that it had been claimed that it was a system of cleanliness; but he denied this. While he had seen enthusiastic disciples of Lister clean the limb of a child four years of age, so that no precaution might be omitted, he had also seen the most approved antiseptic dressing removed from a wound covered with the most fetid pus that he had ever seen in his life.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, February 10, 1885.

The President, Alfred C. Post, M.D., LL.D., in the Chair.

REFRACTURE OF THE FEMUR.

Dr. Post presented a patient, a man 22 years of age, who came under his care between two and three months ago. At that time it was five months since he received a fracture of the right thigh at the junction of the second with the upper fourth, having been struck by the paddle-wheel of a steamer, and for which he was under treatment in a Staten Island hospital for several weeks. Dr. Post found great bowing of the thighs, with the convexity outward, and with a shortening of two and a quarter inches. He sent the patient to the Presbyterian Hospital, where he refractured the bone by means of Rizzoli's osteoclast, loaned to him by Dr. Sands. It was only with a great deal of force that he succeeded in refracturing the femur. He then treated the case with extension and weight and pulley, the weight being twenty-five pounds. It was continued with side splints during a period of six or seven weeks. The patient remained in bed two or three weeks longer, when he was allowed to get up, and there is now shortening not exceeding half an inch. There is a little fulness in the region of the callus, but there is no apparent deformity, except slight anterior convexity. In refracturing, the bone gave way very gradually, the arch of the limb yielding slowly for some time before mobility was perceived. The patient now stands and walks firmly, and there is nothing in his appearance or movements to indicate that shortening exists.

In response to a question asked by Dr. Markoe, Dr. Post said that the inflammatory reaction following the

operation was no more than after the occurrence of ordinary fracture.

ADENO-CARCINOMA OF THE RECTUM.

DR. GERSTER presented a patient, a man 27 years of age, who, since he was eight years old, had suffered from prolapse of the anal mucous membrane at each stool. For the relief of this, he had used injections of cold water for a very long time, the introduction of the nozzle of the syringe being done by his right hand. During the last year and a half, he had noticed frequently more or less profuse hemorrhage with each passage of the bowel. In November last, the patient came under Dr. Gerster's care at Mount Sinai Hospital, where he diagnosticated a tumor on the left side in the posterior portion of the rectum, overlapping somewhat the mucous membrane, but still sessile and ulcerated in the centre. It bled on the slightest touch, and occupied about two-fifths of the circumference of the gut, extending upward so far that it was just possible to touch healthy mucous membrane with the tip of the index finger. It was freely movable. It was evidently a malignant growth, and an operation was performed for its removal by first making an incision from the anal margin to the coccyx and excising the tip of the coccyx. The sphincter being perfectly healthy, the mucous membrane covering it was dissected up, and then the lower margin of the dissected mucous membrane was included in a purse-string ligature, and the rectum thus occluded. Having in this manner provided against the accidental escape of the rectal contents during the operation, the ligature strings were used as a handle to pull down the gut, and exsection of the gut proper was begun and continued with careful precautions as regards the loss of blood, each mass of tissue being secured with a double ligature and division made between, so that there was not more than two ounces of blood lost. Five and a half inches of the gut were removed, including the diseased portion and fully one inch of the healthy mucous membrane beyond. The gut was then cut through and sewed to the edge of the incision in the integument with four stitches. Throughout the operation, the wound was irrigated frequently and thoroughly with a bichloride solution, 1 : 2500. Two drainage-tubes were introduced into the bottom of the wound, and the wound was then loosely filled with iodoform gauze. The whole was covered with sublimate gauze, and the outer dressing was removed as often as was necessary to secure cleanliness. The iodoform gauze was allowed to remain until it could be easily removed. There was no shock attending the operation. The temperature remained normal until the fifth day, when there was some intestinal disturbance due to constipation, showing that careful preparatory treatment did not suffice to clear out the bowels thoroughly. As soon as this was relieved by castor oil, the temperature fell to normal and the wound healed without interruption, and union was complete in about four weeks. Dr. Gerster said he proposed to perform a further operation with a view to changing the location of the anus, after which the patient would again be presented to the Society.

DR. POST asked if any of the members had seen malignant disease of the rectum in so young a patient.

DR. KEYES had had a case in a young woman upon whom he operated whose mother at the time of the operation was suffering from the same affection. The daughter was 22 years of age when she was operated upon.

DR. POST remarked that he had a brother who died of cancer of the rectum at the age of 29 years.

DR. GERSTER then read a paper entitled

THE SURGICAL DISSEMINATION OF CANCER.

(See page 230.)

DR. POST asked if, in the application of the Esmarch bandage upon the distal side of a malignant growth in an extremity, the pressure would not have a tendency to propel the cancerous corpuscles toward the trunk.

DR. GERSTER replied undoubtedly, and said that he spoke only of constriction of the limbs.

DR. SANDS asked Dr. Gerster whether, in the experiments he had made of injecting tumors prior to their removal with some coloring substance which was capable of being transmitted along the lymphatic vessels, he had obtained any results confirmatory of the theory he had advanced in his paper.

DR. GERSTER replied that he had obtained some results which, on superficial examination, might be declared to confirm his assumption; but from further and more careful study of the results of other experiments, the value of the former results was placed very much in doubt. In the first case, he used an emulsion of India ink, glycerine, and corrosive sublimate, 1 : 1000, which he injected into the tumor immediately preceding the operation. On examining the specimen, it became doubtful whether the injection had propelled the India-ink into the lymphatics, or whether this was done by manipulations incident to the operation. Another thing which raised doubt with reference to the value of the first experiment was the fact that corrosive sublimate arrests protoplasmic action. Dr. Gerster's object was to introduce this colored material so that the embryonic cancer cells, which have an amœboid movement, might absorb or take into them particles of India-ink, and then be carried onward into the tissues. If he had found such a cell far away from the place of injection, it would have been almost conclusive proof. Nothing of this kind, however, was found, because the corrosive sublimate paralyzed the action of the cells. Therefore, in the last two cases, he had used a warm solution of salt, 6 : 1000; and, as the specimens were still hardening, he was unable to report concerning the results.

The object of the paper was to direct attention to the clinical features of the subject, namely, that after operations where insufficient tissue was removed, relapses will be established, and the disease will reappear within four weeks after the operation. It would be most interesting to hear of the clinical experience of the surgeons present concerning the disproportionately rapid reappearance of malignant disease, as it had been mentioned, especially by the older writers. It is known that formerly operation was discouraged, because it was believed to induce more rapid recurrence and extension of the disease.

DR. BRIDDON had in mind three or four cases of benign tumors, one in particular, situated in the neck, and operated upon by the late Dr. Buck, and the operation was followed by a disseminated carcinosis of very rapid development. Another case occurred to himself,

in which a granular ulceration, probably epithelioma, of the index-finger was operated upon by amputation, and general carcinosis occurred within six weeks, involving the glandular system, and also the abdominal viscera.

His experience with regard to cancer had been that in those cases in which there was infiltration of the tissue immediately surrounding the tumor, or there were nodules of cancer in the vicinity of the tumor, rapid recurrence of the disease had followed the operation. He recalled the fact that several years ago, Mr. Arnot, of London, introduced the treatment of malignant growths by compression, and his recollection was that some good was accomplished by the method. At all events, he scarcely thought it increased the rapidity of the growth.

Dr. Post referred to the fact that Dr. Batchelder, of this city, introduced the method of treatment by the use of compressed sponges, and in some cases, at least, with apparent good results.

Dr. Sands said that it had been his belief for a long time that in cases of malignant disease, especially of the breast, harm was often done by stimulating applications employed with the object of dispersing the tumor. He had always feared that such applications might prove injurious by exciting hyperæmia of the affected parts and thereby causing a more rapid increase of the swelling. It had not been his experience that operations performed for the relief of cancer had been followed by rapid recurrence, unless there was reason to suppose that the morbid growth had not been thoroughly removed. It seemed to him rather that the chance of exemption from recurrence was in a direct ratio to the completeness with which the work of extirpation could be accomplished. That seemed to be the only explanation of some cases in which what is termed permanent cure had been the result of the operation. He had listened with great interest to the remarks made by Dr. Gerster, who had raised an important question, which, perhaps, could be solved more easily by experiment than by clinical observation. As to the actual risk incurred at the time of operation, it would be hard to decide. He did not wish to disparage a theory which was both rational and plausible, but he thought it might be doubted whether, during an operation performed for the removal of a malignant tumor, the compression exerted would always exceed that to which it might have been subjected at various times prior to the operation. He could also recall instances in which the removal of the tumor had been effected only with very great difficulty, and with the exercise of considerable force, yet in which the patients had afterwards remained exempt from recurrence for a long period. He had presented to the Society within the past year a man about thirty years of age, upon whom he had operated fourteen years previously for fibro-sarcoma of the parotid, necessitating the removal of the entire gland, which was accomplished with great difficulty. Nevertheless the patient remained free from recurrence for more than thirteen years, when the disease reappeared in the cervical lymphatic glands.

Dr. Post thought that incomplete removal of cancerous growths favored recurrence of the disease. Recently he had read an account of removal of a naso-pharyngeal polypus piecemeal—that is, portions at different sittings—until finally the entire growth was removed; and the writer had stated that, during all this time, there was progressive improvement in the symptoms—a statement which struck Dr. Post as being contrary to the general experience of surgeons in dealing with malignant disease.

Dr. Sands remarked that the settlement of the point in question by clinical observation would be rendered difficult by the acknowledged diversity shown by different malignant growths regarding their tendency to dissemination.

Dr. Gerster said he fully admitted the fact that incomplete operations favored relapses. At the same time there were cases on record in which incomplete operations were said to have been followed by cure, although he had doubted such cases very much. He would like to ask why it was that this recurrent new growth changed its type? Why does the recurrent tumor behave entirely differently from the tumor first removed? It was a common experience, even in his short surgical experience, that a tumor which had been growing slowly, after it had been operated upon incompletely, grew much more rapidly than it had ever done. Of course, what he had said was only a suggestion of the necessity of continued investigation, caused by the desire of drawing attention to a fact hitherto little considered in our efforts to combat such an intractable disease as cancer.

Dr. Sands referred to one well-known circumstance which strongly favored the view taken by the writer of the paper—that is, the usually rapid extension of cancer of the tongue, which had been explained by the great mobility of the organ and its constant movements.

Dr. Markoe said that, on the other hand, it is to be observed that one of the most rapidly recurrent forms of malignant disease is that which occurs in the testicle, recurring generally within a very short period of time, and yet there is no operation for extirpation in which the tumor is less manipulated, and in which there is less displacement of cancer cells or juices than in extirpation of this organ.

Dr. Sands remarked that in such a case it would be difficult to decide whether dissemination had not already taken place at the time of the extirpation, because the parts in which secondary deposits occurred were so deeply situated along the posterior abdominal wall that until they had attained a considerable size they would not be recognizable. He had supposed that this was the reason why the removal of the testicle for malignant disease was so rarely followed by a permanent cure. Occasionally, however, sarcoma of the testicle was followed by exemption from recurrence. He had had one such case in which the disease had not returned thirteen years after operation.

Dr. Post said there was one practice not uncommon, that of puncturing a tumor in cases of doubtful diagnosis as a means of ascertaining its character. It appeared to him that puncturing, if the disease were malignant, had a tendency to increase the malignant growth. He referred to a case in point during one of his terms of attendance at the New York Hospital, that of a tumor in the region of the scapula which had developed quite rapidly, and there was some question as to whether it was malignant or inflammatory. Dr. Post had reached the conclusion that it was malignant.

Dr. Mott thought it was inflammatory, and suggested that it be punctured for the purpose of ascertaining whether or not it contained pus. The puncture was made, and the operation was followed by great aggravation of the symptoms, and the patient died from the disease. From the time the puncture was made the disease progressed more rapidly than it had done at any time previously. He thought, therefore, if puncture was made it should be in cases in which extirpation could be immediately resorted to, if the diagnosis of malignant disease was confirmed.

DR. KEYES had had a case quite recently in which the patient also had been seen by Dr. Sands and by Dr. Markoe. It was that of a young man who was born with a mole on his back between the shoulders, which gave him no trouble whatever until he had reached the age of twenty-three or twenty-four years, when another little brown spot appeared within an inch of the original mole, and shortly after became excoriated, began to ooze a peculiar fluid, and looked angry. When Dr. Sands saw the patient, he advised removal of both dark spots, one of which had never ulcerated. The father of the patient had a mole in the same location, but it had never given him any trouble. There was no thickening about the brown spot, so that there was no considerable tumor. These tumors were removed in a neighboring city by the patient's surgeon, and within a reasonable number of months afterwards there appeared upon the back over the scapula upon the same side a lump, as large as a pigeon's egg, which grew rapidly, together with a tumor in the axilla of the size of a goose egg. These lumps were manipulated a good deal in the patient's native town, after which he came to New York where they were again subjected to a great deal of manipulation for purposes of diagnosis. Dr. Keyes supposed the tumor to be a recurrence of the original disease, and advised immediate removal. Dr. Janeway also saw the patient, as did also Dr. Markoe; both confirmed the diagnosis. The tumors were thoroughly removed at the patient's home. Dr. Janeway made the microscopical examination and pronounced both lumps to be melano-sarcoma. There were no other tumors about the patient's body; he recovered from the operation rapidly, and when he visited Dr. Keyes, in November last, he was apparently perfectly well. He promised that on the least appearance of any tumor at any part of the body he would report himself, and, inasmuch, as he had not returned nor reported, Dr. Keyes took it for granted that the disease had not recurred.

As to sarcoma of the testicle, Dr. Keyes had removed a number of them, mostly in hospital, and his experience had been that recurrence had taken place generally in the retro-peritoneal glands. In one case, however, that of a sea captain, there had not been any recurrence after a number of years.

Dr. Keyes further referred to another case in which he performed a double operation. The disease was situated in the parotid gland. A small nodule, which had been under observation for two or three years, was removed from the substance of the parotid. A salivary fistula followed, and a great deal of local disturbance ensued, but from all this the patient recovered. On examination microscopically, the growth was found to contain mucoid tissue, round-celled sarcomatous tissue, and certain alveoli packed with cells, which led to the opinion that the growth was undergoing cancerous degeneration, being what is called a composite tumor of the parotid. The tumor was apparently enclosed in an outside shell, with budding portions, which were softer than the rest of the mass. There was no recurrence after removal for seven years, and then in the line of the old trouble a new nodule developed, which, within one year or eighteen months, was larger than the original growth—perhaps as large as the first phalanx of the thumb. Dr. Keyes removed the second nodule in the spring of 1883. It was an exceedingly disagreeable operation, because the patient became partially asphyxiated by mucus in the larynx, and it was necessary to perform tracheotomy in great haste to save life, and there was considerable hemorrhage, etc. He removed the tumor completely, and with it a small portion of the seventh nerve. The patient recovered promptly and completely; did not have a recurrence of the growth until about one month ago, when a small nodule developed under the angle of the jaw, about half an inch from the old cicatrix, rather painful and hard, not connected with the immediate site of the old operation. The second tumor was examined by Dr. Welsh, who decided that it contained mucoid tissue, sarcomatous tissue with alveoli packed with cells, and branching into the mucoid tissue. Probably the tumor now growing would prove to be a growth analogous to the others which had been removed from the same region.

DR. LANGE recalled one case in which he thought rapid spread of malignant disease was dependent upon surgical interference. The case occurred in the person of a young woman who was operated upon by Prof. Esmarch while Dr. Lange was his assistant, for removal of sarcoma of one of the ovaries. The tumor was so large that it was difficult to bring it outside of the abdomen, and it was necessary to crush it in order to remove it. In this attempt a certain amount of its contents got into the peritoneal cavity. Otherwise the operation was readily performed. The tumor was pedunculated and removed within entirely healthy parts, and there was also no other part of the sexual organs involved. The patient did well for the first two weeks, when nodules could be felt in different parts of the abdominal wall, and, as he recollected, it was not more than two months after the operation when the patient died from diffuse sarcoma of the peritoneum and sarcomatous degeneration of the entire diaphragm, and also of the diaphragmatic pleura. Dr. Lange had reported the case in 1877 as one which illustrated the spread of malignant disease from the original point, involving the peritoneum and other tissues.

CORRESPONDENCE.

THE SPRAY IN OVARIOTOMY.

To the Editor of THE MEDICAL NEWS.

SIR: The following is an extract from a recent work by Dr. Emmet (Emmet's *Principles and Practice of Gynæcology*, p. 715): "In this country, I do not know of any prominent operator who now employs the carbolic acid spray." This statement implies that the writer is not persuaded of the value of spray in ovariotomy. My own experience has led me to an opposite

opinion. Indeed, I should not like to do a laparotomy for any purpose without antiseptic spray. I have been led to this conclusion by the results of 183 cases of removal of cystic ovaries, of which I have lost only 21; but more especially by the result of the last 100 of these cases, only 10 of which were fatal, while 38 were consecutively successful. I feel that to omit the antiseptic spray would be to deprive the patient of one of the ready and efficient elements of success. As I can hardly hope for much better results than those I have cited, and being quite content to let well alone, I shall hesitate before disturbing my present plan of operation by giving up a detail to which I attach much importance.

Very respectfully, your obedient servant,

JOHN HOMANS, M.D.

161 BEACON STREET, BOSTON, Feb. 17, 1885.

LAPAROTOMY FOR GUNSHOT WOUND OF THE SMALL INTESTINE.

To the Editor of THE MEDICAL NEWS.

SIR: In the editorial on "Laparotomy for Gunshot Wound of the Small Intestine," contained in the number for February 21st, you express an opinion in favor of uniting the ends of resected intestine and adverse to the formation of an artificial anus. As the opinion is positive and without qualification, allow me to call attention to the fact that there is not an unanimity upon the point. For instance, in a note to the report of a case of excision of the cæcum for epithelioma, by Mr. Whitehead, surgeon to the Manchester Infirmary, published in the *British Medical Journal*, of January 24th, it is stated that Ruchel has collected 121 cases of resection of the intestine "the conclusion being that the two ends of the bowel should not be united at the time of resection, but that an artificial anus should be established." My impression is that this is the teaching of Mr. Bryant in his excellent series of papers on intestinal obstruction, published in the same journal towards the close of last year, but I have not access to them at this moment. In an operation of this magnitude, now rapidly coming before the profession as a duty, it is desirable that there should be clear understanding of its steps in detail. May I not request you, therefore, to present, at an early date, the evidence and the teaching upon this most important point in progressive surgery?

Yours truly,

J. C. R.

DAYTON, OHIO.

OBITUARY.

LOUIS ELSBERG, M.D.

DR. LOUIS ELSBERG, of New York City, Professor of Laryngology at Dartmouth Medical College, Professor of Laryngology and Rhinology at the New York Polyclinic, and Physician to the Throat Wards in Charity Hospital, New York, died at his residence in New York on the 19th of this month, by pulmonary œdema after a ten days' illness, following a cold contracted in returning from a lecture he had just given at the Polyclinic. For two years he had been suffering with Bright's disease, and although of late his health had become sufficiently reëstablished to relieve his professional advisers from all concern as to any immediate danger his condition was such that he was unable to rally. He was in the 48th year of his life, having been born at Iserlohn, Prussia, April 7, 1837. He leaves a widow and a daughter.

Dr. Elsberg had been prominently before the profession for more than a quarter of a century as having introduced laryngoscopy into America, and as having developed the art successfully as a diagnostician and as a practitioner. His reputation was world-wide and was early established, chiefly by an "Essay on Morbid Growths of the Larynx," which won the prize of the American Medical Association in 1864.

His family came to reside in Philadelphia about 1849, and young Elsberg entered the public schools, graduating in 1854 from the Central High School with the highest honor of his class, and delivering the honorary address at the Commencement. Entering Jefferson Medical College a year later, he graduated from that institution in 1857. He then received the appointment of Resident Physician in what is now the Mount Sinai Hospital of New York, and at the expiration of his term of service, made a visit to the medical centres of Europe. He reached Germany at the time that Czermak was bringing laryngoscopy into notice, and was a member of the first class taught by him, his classmates being Prof. Stœrck, of Vienna, Prof. Lewin, of Berlin, and Dr. Semeleder, subsequently Surgeon to the Emperor Maximilian, whom he accompanied to Mexico, where he remained. Semeleder published the first volume on *Rhinoscopy*, but became interested in other branches of medicine, and is comparatively unknown as a laryngologist; but the three others remained continuously devoted to laryngology, each one of them acquiring professional renown in connection therewith.

In 1861, Dr. Elsberg was made Professor of Laryngology and Throat Diseases in the Medical Department of the University of New York, and established there the first throat clinic instituted anywhere. His connection with the University was severed in 1878. He founded the New York Laryngological Society, and presided over it for many consecutive years. He was the first President of the American Laryngological Association, and was reëlected at the close of his term. He founded the *Archives of Laryngology* in 1880.

Dr. Elsberg was an enthusiast in his profession, and taught his specialty by precept, by example, and by many valuable contributions to current medical literature. While this brought him well-earned fame, his large practice seems to have afforded him no leisure for writing a systematic treatise on his specialty, such as had been long expected from him and as would have had an extensive circulation;—a loss to American medical literature now irreparable. His numerous papers scattered in medical journals and Society Transactions evince independent thought, original research, and comprehensiveness of design. While his reputation rests chiefly on his laryngological work, it is enhanced by original investigations in histology and in acoustics, which are less known to medical men generally than to those interested in these branches.

Dr. Elsberg was a close student, an omnivorous reader, and an admirer of systematic classifications. He was an affectionate relative, a staunch friend, and

a sympathetic physician. His death is a serious loss to American medicine.

At a meeting of the members of the medical profession in attendance at the New York Polyclinic, held on February 21, 1885, the following resolutions were unanimously adopted:

Whereas, In the inscrutable Providence of God, Professor Louis Elsberg has been removed from this life.

Resolved, That in his death science has lost an earnest and indefatigable student, the medical profession an honorable member, and society one with broad and humanitarian sympathies.

Resolved, That we offer to his family assurances of sympathy, and as a testimony of our regard for his character and attainments and a sense of our personal loss in his death, that we, the members of the class of the New York Polyclinic, attend the funeral in a body.

Resolved, That copies of these resolutions be sent to his family, to the Faculty of the Polyclinic, and to the medical press.

NEWS ITEMS.

Meeting of the Sanitary Council of the Mississippi Valley.—The Executive Committee of the Sanitary Council of the Mississippi Valley has fixed the date of the seventh annual meeting of the Council for Tuesday, March 10th prox., and in the city of New Orleans. This is about a month earlier than its meetings are usually held, and the committee assigns as a reason for the change the probability of Asiatic cholera reappearing in the country, and the uncertainty concerning National legislation on public health matters. Invitations are extended to all State and local health authorities in the Valley, and to representatives of commercial and transportation interests.

Election of Foreign Members of the Société de Chirurgie.—At a meeting of the Société de Chirurgie de Paris, held Jan. 21, 1885, MM. Pellizzari, of Florence, and Sklifossowski, of Moscow, were elected foreign associates; Drs. Lewis A. Stimson, of New York, Saltzmann, of Helsingfors, Plum and Studsgaard, of Copenhagen, foreign correspondents.

The Société Médico-pratique de Paris has elected Prof. Roberts Bartholow, M.D., of Philadelphia, a corresponding member.

Harvey's Manuscript Lectures.—The MS. of the original lectures at the Royal College of Physicians by William Harvey, including his earliest observations on the heart and circulation, and delivered by him in and after 1616, were rediscovered in the British Museum in 1877. Dr. E. H. Sieveking gave a description of the little book, and exhibited an autotype copy of one page in his Harveian oration at the College in 1877. He then suggested that it would redound to the honor of the present generation, and be an advantage to the history of medicine, if the whole of the lectures could be published in autotype, accompanied by an intelligible transcript. The handwriting is so crabbed, and there are so many abbreviations, that no one but an expert could succeed in understanding them. Without the valuable aid of Mr. Bond, now the Chief of the British Museum, Dr. Sieveking would have failed in his attempts to understand much, if anything, of the lectures. By dint of severe labor, Mr. Bond succeeded in interpreting one of the lectures, and has now been good enough to make Dr. Sieveking acquainted with a gentleman who will undertake to transcribe the whole of the lectures. Dr. Sieveking's inquiries lead him to believe that no publisher could be found to undertake the risk of publication in the form proposed, unless guaranteed a certain amount of professional support. On the other hand, he calculates that if from two to three hundred gentlemen would engage each to take a copy at a price not exceeding two guineas, the work might be safely proceeded with. Autotyping is a much more expensive process than ordinary printing, and the honorarium to the transcriber would necessarily add considerably to the cost.

Dr. Sieveking, in a letter to the *Lancet*, asks his professional brethren whether they will aid in this labor of love of, and admiration for, our great prototype of the scientific physician? He states that the Presidents of the Royal Colleges of Physicians and Surgeons warmly support the undertaking.

Any communications on the subject may be addressed to Edward H. Sieveking, M.D., 17 Manchester Square, W., or to Messrs. Churchill, 11 New Burlington Street, W., London.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 17 TO FEBRUARY 24, 1885.

Bentley, Edwin, *Major and Surgeon.*—Relieved from further duty at Fort Clark, Texas, and assigned to duty as Post Surgeon, Fort Brown, Texas.—*S. O. 17, Department of Texas*, Feb. 16, 1885.

Patyki, Julius H., *Captain and Assistant Surgeon.*—Leave of absence further extended seven months, on surgeon's certificate of disability.—*S. O. 40, A. G. O.*, Feb. 17, 1885.

Taylor, M. E., *Captain and Assistant Surgeon.*—Assigned to duty at Fort Stanton, New Mexico, as Post Surgeon.—*S. O. 29, Department of the Missouri*, Feb. 21, 1885.

Perley, H. O., *Captain and Assistant Surgeon.*—Granted leave of absence for one month, to take effect about March 5, 1885.—*S. O. 16, Department of Dakota*, Feb. 10, 1885.

Robinson, S. Q., *Captain and Assistant Surgeon.*—Relieved from duty at Fort Spokane, Wyoming Territory, and ordered for duty as Post Surgeon, Fort Klamath, Oregon.—*S. O. 23, Department of Colorado*, Feb. 9, 1885.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING FEBRUARY 21, 1885.

Battle, K. P., *Assistant Surgeon.*—To proceed to Pittsburg, Pa., for temporary duty, Feb. 19, 1885.

RESIGNATION.

Heath, W. H., *Passed Assistant Surgeon.*—Resignation accepted, as tendered, by the Secretary of the Treasury, Feb. 14, 1885.

PROMOTION.

Kalloch, P. C., *Assistant Surgeon.*—Promoted and appointed Passed Assistant Surgeon by the Secretary of the Treasury, from March 1, 1885, Feb. 19, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL OF MEDICAL SCIENCE.

VOL. XLVI. SATURDAY, MARCH 7, 1885. No. 10.

ORIGINAL LECTURES.

ON TAPEWORM.

A Clinical Lecture delivered at the Philadelphia Hospital.

BY JAMES TYSON, M.D.,

PHYSICIAN TO THE HOSPITAL, AND PROFESSOR OF GENERAL PATHOLOGY AND MORBID ANATOMY IN THE UNIVERSITY OF PENNSYLVANIA.

GENTLEMEN: I desire, to-day, to call your attention to a class of cases, the practical importance of which is certainly equal to that of any which you will meet in your daily practice.

The patient, 55 years of age, has always enjoyed excellent health. About five years ago, he first noticed segments of tapeworm in his stools. These appeared to be about one-half of an inch long and one-eighth of an inch in width. During the next two years, segments of the worm continued to be passed at short intervals. Three years ago, he was given the oil of male fern, which resulted in the expulsion, according to his statement, of forty-six feet of the worm, but the head was not expelled. After this, four months elapsed before the segments began to reappear. Since then he has continued to pass them from time to time, and has made various ineffectual efforts to get rid of his guest.

The diagnosis is, of course, made in the reading of the history, but there is much more of interest in connection with this subject of tapeworm to which I wish to call your attention. In the first place, man is subject to more than one variety—probably at least four—and it is a matter of no small importance that the physician should be able to recognize the particular species of tapeworm which infests his patient, because there is considerable difference in the ease with which some of the varieties can be removed.

I have in these bottles two specimens of tapeworm, one of which was passed by our patient, and the second by another man in the hospital. It is plain that they present differences. In the one, the links are broader and shorter, thicker and less transparent. That made up of the broad and short links is a specimen of the unarmed tapeworm, or tænia mediocanellata or tænia saginata, and is the one passed by this patient, while the other is an illustration of the tænia solium, or armed tapeworm.

The tænia mediocanellata is known as the beef tapeworm, because its embryos are found as a rule in cattle, producing the so-called "measled" veal and beef. They have also been found in the flesh of the giraffe. The tænia solium is known as the pork tapeworm, because met in the larval state in the flesh of swine, producing the "measled" pork. The worm passed by this patient, I have already said, is a specimen of the beef tapeworm, or tænia mediocanellata. It is the most common form of tapeworm occurring among us, and I believe also on the Continent of Europe. I am informed by Prof. Leidy that all the specimens sent to him for examination during the past fifteen years have been tænia mediocanellata.

The tænia mediocanellata, or beef tapeworm, is characterized by the presence of a quadrate head .1 inch broad, provided with four suckers, placed one towards each angle of the head, and a small central rudimentary sucker, around which, also, according to Leuckhart, there are small rudimentary hooks. The tænia solium has a smaller head, the size of a small pin, provided, in addition to the four suckers, with a proboscis or snout called a rostellum, which is in the front and centre of the head. The rostellum is surrounded by a double circlet of hooklets, those in the inner row being the longer. There are from twelve to fourteen in each row, making in all twenty-four or twenty-eight. The heads of both worms are at times more or less pigmented. There is also a difference in the segments. There are many details to which I shall not allude, but speaking generally, it may be said that the segments of the mediocanellata are broader and shorter, thicker and less transparent than those of the tænia solium. The ripe segments of the tænia saginata average, when released, from .63 to .78 inch long and from .2 to .27 inch broad. The ripe segments of the tænia solium average from .35 to .39 inch long and .15 to .23 inch broad. Tapeworms are hermaphroditic, both sets of reproductive organs being contained in one segment. The peculiarities of these organs will be further considered when I come to speak of diagnosis. As to the length of the entire worm, the tænia mediocanellata is put down at from fifteen to twenty-three feet, but I have known more than forty feet passed. The tænia solium is usually much shorter —from seven to ten feet, or even longer.

How do these tapeworms obtain access to the intestine of man? As already stated, the larva or cysticercus of the mediocanellata is found in "measly" beef. The eggs containing the larval or embryo worm are in some way ingested by cattle. The envelope with which the embryo is surrounded is dissolved, and it works its way, by the aid of three pairs of hooks, with which it is provided, through the intestinal walls and invades the muscular tissue. It is a singular fact, however, that the "measles" of tænia saginata very rarely come under observation. When found, the cysticercus of this worm is an oval cyst scarcely as large as a pea, and is probably often overlooked. Notwithstanding its apparent rarity, it is very often responsible for tapeworm in man.

In the case of the tænia solium, the links of the worm thrown off by man are eaten by the pig, and during digestion the shell of the egg is dissolved, and the embryo liberated. The embryo of the tænia solium is not provided with the double row of hooklets, but, like that of the tænia saginata, with six hooklets arranged in pairs, one central and two lateral. The central pairs are simply stilettos for boring; the lateral for tearing and propulsion. By these means, it attaches

itself to the intestinal wall, and bores its way through into the intermuscular tissue of the animal. The embryo becomes encysted, and thus the cysticercus cellulosæ telæ is formed, and the pork becomes "measled." The "measle" of pork is larger than that of beef. In the former, it sometimes reaches a length of nine-tenths of an inch, while in the latter, it is, as a rule, not more than one-fourth of an inch in length.

The laws demanding the inspection of pork and beef are causing the tapeworm to become less common, but it is still quite so. At the present day we are much less in the habit of eating uncooked pork than rarely done and raw beef. This is also the case in England. It is on this account that the pork tapeworm is less common in these countries than the beef tapeworm. In the middle of Germany, it is less unusual to eat uncooked pork, and although the laws of inspection there are very stringent, the tænia solium is the more common variety of tapeworm. But in Holstein, Heller, the author of the article on tapeworm in Ziemssen's *Cyclopædia of Medicine*, has met the tænia saginata four times as often as the tænia solium.

The first of the remaining varieties of tapeworm to which I invite your attention is the bothriocephalus latus. It is distinguished by the greater width of its segments and their shortness in an antero-posterior direction. You will remember that in the tænia mediocanellata the proglottides, as they are also called, are broader and shorter than they are in the tænia solium. In the bothriocephalus latus, they are still broader and shorter. These statements refer to the average, for the links taken from different parts of the same worm vary much in their dimensions. Still more different is the head of the bothriocephalus latus from that of either of the two which I have described. It has neither rostellum nor hooklets, is club-shaped, .1 inch long and .04 inch wide, and is characterized by two lateral depressions. The head is, therefore, less formidable than that of either of the two other worms. This worm is not often met with in this country. It is more common in Switzerland and Russia, but is also found in Ireland, Sweden, and Germany, and is called the Irish tapeworm as well as the Russian and Swiss tapeworm. It is believed that the cysticercus of this variety of tapeworm is found in certain fish, of the salmon and trout family, and that man acquires the worm by eating these fish uncooked. The length of the bothriocephalus is put by Heller at from fifteen to twenty-five feet, but if it be the longest of the tapeworms, as is also generally stated, it must at times far exceed this.

There is still another form of tapeworm which there is reason to believe is more common than ordinarily supposed. This is the tænia flavopunctata. It is a little tapeworm not exceeding twelve or fifteen inches in length. In the July number of the *American Journal of the Medical Sciences*, Dr. Leidy describes the segments of one of these worms from specimens sent to him for examination. They were passed by a child three years of age, after the administration of santonin. In fact, all the specimens of this worm heretofore described seemed to have come from children, fifteen months to three years of age. It is characterized by its shortness. The joints are proportionately short in all cases, the breadth exceeding the length several times. They are transversely linear, slightly wider back of the middle, with the posterior angles rounded, and the posterior margin slightly but irregularly crenate. The anterior immature joints exhibit no distinct traces of sexual organs, while succeeding ones have a more coarsely granular appearance due to the presence of immature eggs. The pair of longitudinal vessels common to all tapeworms are conspicuously visible in the segments. At the posterior part of the body, the joints in a ripe condition are of a pale brown color due to the contained eggs. The ripe joints are interrupted here and there by a variable number, one or more, of sterile joints. The ripe joints are longer, broader, and thicker. The eggs distend the joints, and are diffused throughout a simple cavity bounded by thin parietes, and are not inclosed in ramified or dendritic uterine pouches, as is the case with most tapeworms. In Dr. Leidy's specimens, the mass of eggs so concealed everything in these joints that the generative apparatus could not be determined. But in the joints devoid of eggs, there was to be seen a narrow clavate organ which Dr. Leidy suspected to be the seminal receptacle, together with four or five oval bodies, probably testiculæ. In these joints only, as a rule, could the genital aperture be recognized at the lateral margin of the joints, immediately behind the middle.

The joints of this tapeworm range in length from $\frac{1}{125}$ inch in the neck to $\frac{1}{50}$ inch, an inch from the posterior extremity; and in width from $\frac{1}{40}$ inch in the neck to $\frac{1}{10}$ inch, an inch from the posterior extremity. The mature eggs are raw sienna-colored, mostly spherical, and $\frac{1}{315}$ inch in diameter.

The specimens sent to Dr. Leidy were parts of three worms, so that it would seem more than a single worm may infest the host, which is the case with other cestoid worms.

One other instance, only, of this worm has been described, by Dr. Weinland, of Cambridge, Mass., and named by him tænia flavopunctata, in consequence of yellow spots lying near the middle line in each successive joint, and representing, according to Dr. Weinland, the testicle. This spot had disappeared in Dr. Leidy's specimen, as it had also in Dr. Weinland's when it reached Prof. Leuckhart some years afterwards. The enclosed embryos are oval and are provided with six hooks arranged in three pairs. The intermediate or larval condition of this worm is unknown. I have taken some pains to describe the tænia flavopunctata, because, as I have already said, it may be more common than is usually supposed, and it is desirable that we should all possess a greater familiarity than we have had, that we may recognize it when we meet it.

Symptoms.—Given a tapeworm in the human intestine, how is it to be recognized? It has occasionally happened that the parasite has been present without giving rise to any symptoms, having been accidentally discovered by the expulsion of segments; and this seems to have been the case with our own patient.

The symptoms occasioned by its presence may be put down in general terms as those of irritation. They may be either direct or reflex. Among the direct symptoms are vague abdominal pains, nausea, and meteorism. Nausea is very common, and both it and the pain are easily accounted for by the irritation of so large a mass of living matter in the intestine. The reflex phenomena include a great variety of nervous symptoms,

among which may be named headache, vertigo, dizziness, epileptiform convulsions, reflex paralysis, and even insanity. Among other symptoms are loss of appetite, together with faintness, and other disorders of digestion, derangement of vision and of hearing, such as noises in the head. Itching and dryness of the nose and anus, and vague pains throughout the body are sometimes noted. Sensations of weariness and vague discomfort may alone be present.

Notwithstanding the presence of these symptoms, we are often compelled, in the absence of positive demonstration—*i. e.*, the passage of pieces of the worm—to administer a purge, in the action of which segments will be passed, if a worm is present.

It is not only as tapeworm that the system is in danger from these parasites. Human flesh may also become "measled." Although the beef measle has thus far never been found in man, some sixty or seventy cases have been noted in which the pork measle or cysticercus cellulosæ is said to have caused death. As I have explained, the embryos already contained in the links of the worm are developed into cysticerci in a second host, as swine in the case of the tænia solium, and cattle in that of the tænia saginata. When cysticerci infest human beings, the embryos may have been introduced with food or drink; but more frequently the links are regurgitated[1] into the stomach, and there dissolved by the gastric juice. The embryos, thus released, migrate into the tissues and become there encysted. Among other situations in which cysticerci are found, the brain and cavity of the eyeball may be mentioned. In the former, a train of symptoms are developed which sometimes suggest a diagnosis. In other situations, they seldom give rise to any symptoms.

Another effect in the human being, of tapeworm, is the "hydatid cyst." This is the result of the ingestion of the embryo of a little tapeworm known as the tænia echinococcus or hydatid-forming tapeworm. This little tapeworm, which is not more than one-fourth of an inch in length, is very common in dogs. It is an interesting fact that in those countries where the intercourse between men and dogs is most intimate, hydatid cysts are most frequently met. Their most common seat is the liver. It is said that in Iceland, where there are many more dogs than people, some physicians have as many as a hundred cases of hydatid disease under their care at one time, and it has been estimated that the number of cases is not less than 10,000. It is in consequence of the intimate association of men with dogs that the larvæ of the tænia echinococcus enters the human alimentary canal. It may find entrance with food and drinking water, which may contain scores of these larvæ, and yet appear pure. Or the embryos may be inhaled with dust. From the stomach they may enter the intestine, and, boring through its walls, pass into the liver, developing there the hydatid cysts. I may at some future time have something to say about this disease, so common in Iceland, and comparatively frequent in England, but quite rare with us.

Diagnosis.—I have intimated that it is a matter of no small importance that we, as physicians, should be able to distinguish the different varieties of tapeworm. For, as has also been stated, the difficulties of treatment vary considerably with the different worms, the tænia saginata being much more easily dislodged than the tænia solium; and the bothriocephalus latus perhaps easiest of all. In the first place, the frequent spontaneous expulsion of segments of worm may be taken as presumptive evidence that they belong to the tænia saginata, as those of the tænia solium rarely drop off. Again, the segments of bothriocephalus latus, while occasionally expelled, are seldom expelled singly, being discharged in pairs or several joined.

The segments of the tænia saginata are stronger, thicker, and less transparent, and, when expelled spontaneously, contain very few eggs. The uterus, which contains the eggs, and which may generally be demonstrated by allowing a segment to dry on a piece of glass, or, better, slightly compressed between two glass slides, is composed of a central canal with lateral branches which are more distinct and less numerous in the tænia solium, from 9 to 12, than in the tænia saginata, where they number from 15 to 20. The genital pores are lateral in the case of the tænia solium and tænia saginata, but central in the bothriocephalus, which has also a brown rosette-shaped uterus very easily distinguished from that of the other two more common forms of tænia.

Prognosis.—This is favorable, as a rule, in all forms of tapeworm, but the tænia saginata and bothriocephalus latus are much more easily dislodged than the tænia solium, the head of which often eludes removal for a long time, the segments continuing to reproduce themselves until the head is dislodged. From eight to twelve weeks are usually necessary for the worm to redevelop itself to a size at which segments are again discharged.

Treatment.—There is, perhaps, no one condition which has brought more opprobrium upon the medical profession and more "grist to the mill" for quacks, than tapeworm, and to our humiliation it must be said that quacks do seem to have more success in getting rid of tapeworm than we do. There are, I think, two reasons why this is so. In the first place, it is certain that they do not use different remedies from those commonly in use by the profession, but they give larger doses. In the second place, they see a large number of cases and develop a sort of specialty, which, like all specialties, produces greater skill in treatment. When I say quacks, I mean more particularly advertisers and those who use secret remedies; for in their treatment of tapeworm, they undoubtedly use remedies which experience shows to have been useful.

In order that a tapeworm may be successfully treated, it is necessary that it shall have a certain size; so that, if a large part of the worm has been brought away by medicine, it is useless to give anything more until the remaining part increases sufficiently in size.

There are half a dozen remedies for tapeworm, and they are all good. I think that the two best are probably the ethereal extract of male fern and kooso. Some prefer the first of these, while others prefer the second. In my hands, kooso has been decidedly the most efficient—that is, having failed with everything else and having succeeded with kooso, it has naturally become the remedy with which I always begin the treatment. It is the dried flowers and immature fruit of the Brayera

[1] Portions of tapeworm thus regurgitated may even be passed by the mouth.

anthelmintica, a tree native to Abyssinia. It is given in the form of a powder, and the only objection to it is its bulkiness. The dose is laid down as a half to one ounce of the powder in half a pint of water. I prefer to give the larger dose, for it is harmless, except in pregnancy, and I am sure that failures are often due to the smallness of the dose administered. Kooso is said to have produced miscarriage; therefore, it should not be given to pregnant women.

Patients require some preparation before any remedy is employed. I always tell them to eat nothing from noon of one day until the next morning, when one ounce of kooso in half a pint of water is directed to be taken. If at the end of six hours no movement of the bowels has taken place, a promptly acting aperient, as a dose of oil, compound jalap powder, or elaterium, is taken, but generally kooso requires no purgative after it. This usually brings away the worm entire. Of course, you are never certain that you have the entire worm until you find the head. At the same time, it does not follow because the head cannot be found, that you have failed to remove it, for it is very small, and may have been lost in the discharges. As I have said, in the tænia solium the head is about the size of a small pin's head; in the mediocanellata, it is somewhat larger, and in the bothriocephalus latus it is still larger. If the head has not been removed, you may be certain that in a certain length of time the worm will grow out again. This varies from ten to sixteen weeks.

Instead of kooso, the resin which it contains, called *koosin*, may be given; but I have had no experience with it. The dose is 20 to 40 grains enclosed in a wafer.

The next remedy in efficiency is the ethereal extract of the rhizome of Aspidium filix mas, whose active principle—an oleo-resin—is extracted by ether. The preparation of the patient is about the same as for kooso. The dose is half a fluidrachm to a drachm. The larger dose should be given. It is a dark, thick liquid, bitter, slightly acrid, and nauseous. Instead of the ethereal extract of male fern, the oil may be given in a gelatine capsule, which is the best vehicle for these unpleasant oils. Six or eight hours later, a dose of purgative medicine should be administered. An important point to be borne in mind, is the varying quality of these drugs, and that they deteriorate with age.

The next remedy in order of efficiency is the bark o the root of the pomegranate. This has been given in the shape of a decoction, about two ounces to the pint, and the dose is a pint. Recently, there has been introduced an alkaloid obtained from pomegranate, named pelletierine, in honor of the chemist, Pelletier. This is sold in a single dose, the price of which is, I believe, three dollars. When first introduced, it was vaunted as a "sure cure;" but the experience of practitioners in this city has not been uniform, and success has been by no means invariable. Very recently, however, I have known a case to have been successfully treated with pelletierine after all else had failed, including large doses of turpentine, and including pelletierine itself. When successfully used, the dose of pelletierine was given after twenty-four hours' fasting and no preliminary purgation. In fifteen minutes afterwards, one drachm of compound jalap powder was taken. In an hour and fifteen minutes, the entire worm, including the head, was passed. When pelletierine was unsuccessfully used, it was preceded by a day and a half fasting, during which two doses of castor oil were taken.

Kamala, the hairs of the Rottlera tinctoria, is said to be very efficient in tapeworm, but I have had no experience with it. It is given in doses of from one to two drachms suspended in syrup, repeated in eight or ten hours if it do not purge. It is purgative, sometimes drastically so. It may also cause nausea and vomiting.

Another remedy, which is an excellent one in this affection, is oil of turpentine. At the same time, it is apt to produce such unpleasant symptoms that it would be the last which I should use. The dose is from an ounce to two ounces mixed with twice that amount of castor oil.

The last remedy which I shall mention is pumpkin-seed. This was used very commonly some twenty years ago. It was the remedy which I always used until frequent failures induced me to give it up. There are two ways in which it may be given. Two ounces of the seeds may be crushed in a mortar with water, then strained, and the emulsion taken fasting, the patient having dieted the previous day. A few hours later, a brisk purge should be taken. Or the seeds may be made into an electuary, which is almost as pleasant as sugar candy, and often is about as effectual.

I should place these different remedies in the order of their efficiency as follows: kooso, male fern, pomegranate and pelletierine, kamala, turpentine, and, lastly, pumpkin-seed. I am inclined, however, to give pelletierine an early trial, in consequence of its recent successful use in the manner referred to.

I have already stated that it is important to know the variety of worm present for the purposes of prognosis and treatment. The easiest of these worms to dislodge is the bothriocephalus latus, because it has neither the hooklets nor the rostellum of the other varieties. The next in ease of removal is the tænia mediocanellata, which, although it has the four suckers, lacks the hooklets which give the tænia solium its firm anchorage. Of all the forms of tapeworm, the most difficult to dislodge is, therefore, the tænia solium; for it not only has the four suckers, but also the double row of hooklets. I believe, however, that if a more active course of treatment than is usually recommended be pursued, our efforts will be more successful.

CÆSAREAN OPERATION IN A DWARF.

BY ELY VAN DE WARKER, M.D.,
OF SYRACUSE, N.Y.

AT two o'clock on the morning of the 14th of January, I was called by Dr. Saxer, of this city, to meet several physicians who, for some hours, had been in attendance upon Mrs. Franklin Roberts, known as the "Midget," in labor. Dr. Saxer informed me that the physicians in charge were unanimous in the opinion that the Cæsarean section was unavoidable, and that they had selected me as the operator. After a brief conference with the doctor, I accepted the offer. I had my near neighbor, Dr. D. M. Totman, called up, and with my assistant,

Miss F. A. Adams, we were in a short time prepared for the operation. Fortunately, my sponges and ligatures were ready, as I had just cleaned up after an abdominal operation, so no time was lost upon my part.

I arrived at the house of the patient at 3 A.M., and found Drs. Glauner and Searl in attendance. I was shown the patient, a most wretched appearing little creature said to be 30 years old. She was in a state of great alarm, moaning incoherently, and from whom I could not get an intelligent reply. Her pulse was about 120, and of poor quality, while her attenuated limbs showed a very impaired nutrition. I examined her, and found a leg and foot protruding from the vulva, which had been brought down in a vain attempt to deliver by the breach. The pelvis was so completely occupied by the thigh that, aside from the great contraction of the pelvis, I could learn but little. The head of the child was in the left ilium, the breach in the right, which position deflected the left flank of the mother considerably beyond the crest of the ilium, giving the abdomen a very distorted appearance.

It would be impossible to conceive of worse surroundings for an operation of this character. Her quarters consisted of two small up-stair apartments in a tenement house, occupied as living and sleeping rooms by six people. It was one of the coldest nights of this month, with a northwest wind-storm driving against the windows. The rear room was selected for the operation, as it was without a carpet, and I doubt if it at any time reached a temperature of 70°. We worked a spray apparatus industriously in the room, but it was not directed upon the patient on account of the low temperature. Fifteen minims of "normal" extract of ergot were given hypodermically just before administering the ether. The character of the pulse improved under the anæsthetic. The abdominal incision followed the linea alba, and not the centre of the distorted abdomen, in order not to sever the fibres of the muscles. The abdominal incision was bloodless, and I noticed the absence of subcutaneous fat. The uterus was exposed in a state of firm contraction. The uterine incision was made about four inches to the right of the centre of the organ, and I found the placenta lying directly under. I separated it quickly, and removed it, and extracted a dead child by the breach. The delivered leg was so firmly fixed in the contracted pelvis that Dr. Totman was obliged to aid in its extraction from below. After the removal of the child, the uterus contracted with great energy. The uterine incision was closed by interrupted sutures of iron-dyed silk. The toilet of the abdominal cavity was made with care, and the suturing of the external wound made with the same material. About three drachms of dilute alcohol were given hypodermically directly after removal from the table, followed in about half an hour by seven minims of Magendie's solution. Reaction was encouraged by heated dry flannels and hot water bottles; and when I left her, at half-past four, she was in fair condition.

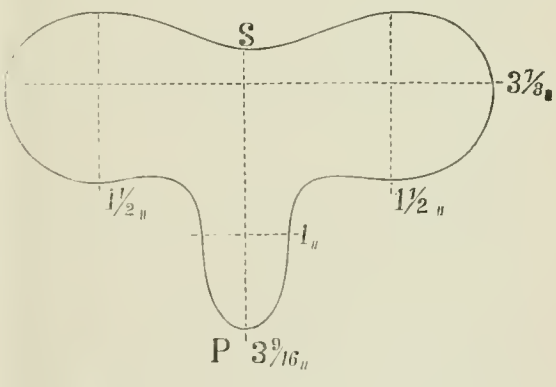
14th.—9 A.M., temp. 99.5°; pulse 120; resp. 20. Has had a discharge of blood from the vagina, about equal to that after normal labor. Free from pain. 6 P.M., temp. 103°; pulse 120; resp. 20. Uneasy and disturbed by flatulence. Gave seven minims Magendie's solution hypodermically.

15th.—9 A.M., temp. 101.5°; pulse 135 to 140, poor in quality. Has had a restless night. Milk and lime water given in small quantities were rejected. Stimulants and beef juice given by rectum. 6 P.M., temp. 102.5°; pulse 140; resp. 20. Abdomen distended with flatus. Vomiting a dark fluid frequently. Seven minims Magendie's solution hypodermically.

16th.—9 A.M., temp. 103.4°; pulse counted with difficulty, about 140. Has not vomited since. 4 A.M., abdomen considerably distended; very restless. 11.30 A.M., death.

17th.—10 A.M., post-mortem examination by Dr. Totman. Externally, she presented the appearance of a child between six and seven years of age. From the knees up she was symmetrically formed. The right tibia showed a marked antecurvature, the left was slightly curved, and the left leg one inch shorter than the right. Measured upon the longer limb, she was 36 inches high. She was said to weigh in health 60 pounds. There was beginning union in the upper part of the abdominal incision. The abdominal cavity presented a few red, longitudinal streaks; otherwise, normal. No signs of union in the uterine incision. The uterus was firmly contracted, and the coaptation of the edges of incision perfect.

The uterus was removed, and the pelvic diameters measured with a pair of carpenter's calipers. The following outline sketch, with the measurements annexed, will give a better idea of the character of



the pelvis and the contractions of its inlet than it is possible to give by verbal description: *s*, corresponds to the sacrum; *p*, the pubes. The pelvis belongs to the class of pseudo-osteomalacia of Michealis. Its outline presents a uniform trifoil form, and was produced during the rachitic period by the acetabula pressing inward and upward with equal pressure. The distance between the iliac crests was six inches. The child (male) weighed 7½ pounds, and measured 20 inches long.

In the course of my hasty preparations, I had resolved to make Porro's operation; but when I saw the surroundings of the patient, I concluded that complete closure of the peritoneal wound was the

Women saved, 7; lost, 19. Whites, 19; Blacks, 7 Whites saved, 5; Blacks, 2 Children saved, 12; lost, 14; by craniotomy (†), 3. Case 20–21, is (1885) still living Shortest woman saved, 3 ft. 9 in. Shortest known, saved, 35 inches (in Brest, France, after 1½ hours labor). Shortest Porro case saved in Europe (Vienna., 3 ft 1 in ; labor, 10½ hours. Uterine sutures were used (‡) in cases 4, 8, 11, 16, and 25. An *early* operation in a dwarf must be considered in reference to her comparative size, and the attempts that may have been made at delivery. Undue loss of blood in the operation is almost necessarily fatal, and exhaustion takes place much earlier than in the average woman To save a dwarf under 4 feet, will require an early operation, and no attempts at turning or craniotomy. One-fifth of the Cæsarean operations in the United States have been performed upon dwarfs, of whom 73 1-13 per cent were lost, and this degree of fatality was largely due to delay in the use of the knife.

safer for the patient. After the patient was placed upon the table, an examination convinced me that laparoelytrotomy is not practicable in the extreme dwarf subject. So firmly was the uterus drawn down upon the pubic spine, that it would have been impossible to have found room for the necessary deep dissection. What may have been the condition shortly after the beginning of labor, I do not know, but it is easy to see that as labor advanced, the force of uterine contractions was expended upon the greatly narrowed pelvic spine instead of the inlet.

Shortly after the date of the operation, Dr. Robert P. Harris, of Philadelphia, the eminent authority upon the Cæsarean section, informed me that since April 6, 1884, there have been six Cæsarean operations in this country, four of them in the last nine weeks, and all ending fatally to mothers and children.

Dr. Harris also sent me the accompanying valuable table, with permission to append it to this report. The note following the table, which is also by Dr. Harris, explains the cause of death in my case, although the amount of blood lost would certainly not more than equal the average amount attending the delivery of the placenta in normal labor, yet, in connection with the shock, it proved too much for the weight and inches of my patient.

CASE OF DERMATITIS HERPETIFORMIS, WITH PECULIAR GELATINOUS LESIONS.

By LOUIS A. DUHRING, M.D.,
PROFESSOR OF SKIN DISEASES IN THE UNIVERSITY OF PENNSYLVANIA.

John S., æt. 64, a native of Wilmington, Delaware, and a peddler by occupation. He has always enjoyed good general health; weight, 175 pounds. No family history. The present skin disease is of five years' duration, but he has had the same only in winter. It has been in the habit of coming on with cold weather and disappearing about the middle of May, and it has pursued this course every year. He never had any skin disease or illness of any kind before seven years ago, when an "eczema" of the right leg appeared, which has been cured repeatedly by ointments, but has relapsed. He is of the opinion that the disease of the general surface which he now has is the same disease that he has had for the last five years; but that it is worse this winter than ever before. When it first came out (in October, 1874) he was in his usual good health. It manifested itself by intense itching on the back, localized chiefly about the lumbar region, which asserted itself in paroxysms, lasting from a half-hour to two hours. They were invariably relieved in the course of ten or twenty minutes by scratching. Unless scratched or rubbed, itching would persist for hours. The itching was unaccompanied by redness. The scratching did not injure the skin, notwithstanding that he was in the habit of employing harsh measures for relief. This pruritus continued all winter, confined to the back, and at no time was accompanied by any eruption. With May it disappeared quite abruptly, as soon, he states, as he began sweating in the course of his pedestrianism. He was entirely well all summer. until October, when the disease again began as in the previous year with intense itching without eruption, and confined to the back, occupying, however, more surface than before. It continued all that winter, as during the previous season, and again disappeared in May.

The following October it reappeared, and now for the first time in the form of small, pinhead-sized, elevated, inflammatory, acne-like, very itchy pustules, which, after having been emptied, disappeared. They were scattered over the back, and were not grouped. They came at irregular intervals, and not in crops. They were present throughout the autumn and winter in varying numbers, and entirely left him in May. The itching was quite as intense as during the two previous years. He states that after these lesions were opened and scratched, decided relief was experienced. In October (third year), itching upon the back again manifested itself, which gradually increased in severity, and continued all winter. The small inflammatory, acne-like, pustular lesions which were present during the second winter did not reappear; but toward the middle of April, what he describes as small, "blind-boil-like" lesions appeared on the back. They neither discharged nor crusted. Two or three came at a time and were very itchy at first, but in the course of two or three days became sore. In the course of the following month there occurred some twenty of these lesions, when, toward the middle of May, they entirely disappeared.

He remained well through the summer, as usual, until October, when the itching confined to the back began as before, unaccompanied by eruption, but a week later the itching began to subside, and now a new kind of lesion appeared, which he describes as follows: When first noticed, two were present over the right scapular region. They were the size of a large thumb-nail, distinctly raised, but flat, with little or no inflammatory areola, of a golden-yellow color, and contained a thick, consistent, orange or deep golden yellow-colored mass. These lesions were in many ways peculiar. They came suddenly, often in the course of ten or fifteen minutes. His attention would be directed to the affected part by a sharp sensation, "like the sting of a bee;" examining the skin he would find one or more lesions present, and, as a rule, already fully formed. They were neither preceded by, nor accompanied with, itching: the sensation was that of a sting. They were superficially seated, appearing to have their seat just beneath the epidermis. They would continue "to sting" until opened with a knife or needle, a knife being the instrument usually selected for the purpose. (He was at this period an inmate of the Wilmington Almshouse Hospital, and was under the care of Dr. Thomas Ogle.)

The lesions were too tough to permit of being ruptured with the finger-nail. He describes them as being circumscribed, firm but not hard, "puffed-up," raised but flat on their summits, and movable under the skin. Some were raised as much as a quarter of an inch or more; others less. As soon as he became aware of their existence, by the stinging sensation, they were opened; the sting was sharp and persistent until they were evacuated. All of these lesions were

much alike as to size, shape, color, and other general characters. When opened with a knife, the mass or contents referred to would come out, or "pop out" entire, without any pressure being exerted, and in the form of the pulp and of the consistence of an ox-heart cherry; the mass was, however, flattened rather than round.

These curious pulpy, gelatinous masses, he states, could be picked up between the fingers, handled, and, if squeezed, would disintegrate. No blood accompanied them, nor did the cavity which remained after the exit of the mass contain any blood, but it subsequently oozed a few drops of a yellowish fluid, of a creamy consistence. A cavity, of course, remained after the exit of these bodies, into which the tip of the index finger could be inserted; but, under a stimulating lotion of iodide of potassium, this healed over, with slight scaling, in a few days, no stain remaining. Sometimes these cavities would refill, and often with surprising rapidity, in less than ten minutes with a material similar to the first product, but not so yellow, and invariably thinner—more of the consistence of thick cream—which could be squeezed out by pressure with the blade of a knife. But not all of the lesions would refill; some would refill as often as three times, and this in from one to twelve hours. He continued to have these very singular lesions throughout the autumn and winter, one, two, three, or more making their appearance, on the average, every day. They did not come in crops, but at irregular intervals, and, as stated, seldom oftener than at the rate of one or two daily. They were at first confined to the back, but subsequently attacked all portions of the surface except the face and scalp.

They disappeared gradually in the following April, and he was free from these and all other lesions throughout the summer.

Present condition, January 13, 1879: The patient was admitted to the Ward for Skin Diseases of the Philadelphia Hospital on November 1, 1878, but did not come under my observation until some weeks later. When admitted, he presented a slight vesicular and papulo-vesicular eruption, in patches and much scratched, occupying the back, abdomen, and extremities. It appeared to be trivial eczema, although he complained greatly of the itching, declaring that it was intolerable. The case, as stated, was regarded as one of eczema, and was placed upon the usual treatment for this disease. The disease disappeared, in a great measure, in the course of a fortnight, but soon recurred, exhibiting the same characters as before.

December 15.—An outbreak of vesicular eruption has recently appeared, showing the lesions in a more positive form. They are *vesicles*, varying in size from a small pin-head to a pea, and possess irregular, angular, jagged borders, such as are encountered in herpes zoster. Although manifestly inflammatory, they are unaccompanied by marked signs of inflammation, being for the most part altogether without areolæ, though the skin between them is somewhat reddened and considerably excoriated from scratching. They are, as a rule, quite flat, but some are raised, looking as though they might develop into blebs. Their contents are either clear and watery or pale yellowish. Those which are flat, and contain a clear fluid, are inconspicuous, and even in some places difficult to detect, and resemble sudamina. The lesions show a distinct disposition to form patches, and, moreover, to cluster, and here and there even to run together; but the grouping is not pronounced, and might readily be overlooked by a casual observer. The back of the neck, shoulders, back, arms, and thighs are the regions especially involved, though other parts are also invaded, but with disseminated, abortive, papulo-vesicular, more or less excoriated lesions.

Antipruritic lotions have been freely used, but with indifferent results, an alkaline tarry preparation affording the most relief. The itching has been intense, preventing sleep and causing the patient to scratch incessantly day and night.

The vesicular lesions above described gradually subsided in the course of two weeks, leaving the skin quite free of lesions, except a general dirty-yellowish pigmentation, the result of scratching. The patient remained well, except that he was still much annoyed with general itching for a week, when the present lesions, pustular in character, began to appear. They have been very gradually increasing in size, and multiplying from day to day, until the existing condition has been reached.

The lesions are distinctly *pustular*, varying in size from a pin-head to a finger-nail. They are of a yellowish-white color; tensely distended in their early stage; flat; surrounded with marked areolæ; and of irregular, more or less rounded or angular outline, and have a contracted or puckered appearance. The older ones are crusted with a yellowish, slightly greenish, flat, uneven, honeycomb crust. The recent small crusts, in many instances, show a decided umbilicated or cupped formation, reminding one of tinea favosa.

The lesions are numerous, and exist upon the scalp, neck, shoulders, arms, forearms, sacral region, buttocks, thighs, popliteal spaces, legs, breast, and abdomen. The hands and feet and genitals are almost free. Viewing the eruption as a whole, the lesions may be said to be disseminated, though they are more abundant in some localities than others, and in some places—as on the buttocks—even incline to cluster. The clusters or groups are made up of two, three, or four lesions, of different sizes, situated closely together, in some instances so closely as to run together. Two decided clusters, of half-dozen lesions each, occupy either buttock, the lesions being small and large, inflammatory, more or less crusted, and evidently increasing in size, accompanied with severe itching.

27th.—The course of the lesions has been carefully noted from day to day. While the greater number of pustules appeared simultaneously during the first few days of the outbreak, new ones have not ceased coming out up to the present period. As a rule, the pustules have started as pin-head or split-pea sized lesions, and have slowly and gradually increased to their determinate size, this varying from a split-pea to a silver half dollar. The time occupied for the growth to the largest size named has been from two to three weeks, a remark-

ably slow growth considering the character of lesions. Many of the smaller ones have assumed their determinate size and have begun to disappear in the course of a week or ten days. In almost all instances, the increase in size has taken place plainly in the form of a complete or broken, narrow ring of flat pustules, which has been kept up just beyond the line of the central crust; as rapidly as this would form, the ring or circle (often imperfectly developed) would appear, which in turn would become merged into the central crust.

Many of the older crusts have been dropping off, leaving dark red, more or less pigmented areas of infiltrated skin. Since the attack began to subside, the itching has decreased, and he now experiences great relief and comparative ease. During the outbreak, "liquor picis alkalinus," a drachm to two or three ounces of water, has been used as a lotion to one side of the body; while on the other half, fluid extract of grindelia robusta, one drachm to the ounce of water, has been employed. The patient states that both remedies gave relief, but that he prefers the tarry preparation. He has also been taking a pill of one-thirtieth of a grain of arsenious acid and a saline laxative as required.

February 4.—No new lesions have appeared, and the recent attack has completely subsided, the skin being in better condition than it has been for many months. Considerable pigmentation, however, remains, and the dark red spots, scattered and in groups, the seat of former pustules, are likewise conspicuous. The itching has abated, though he states that he is still obliged to scratch at night.

22d.—Improvement has been slowly going on during the past fortnight, the pigmentation and staining being, however, very tardy in disappearing. The patient remarks that he fears another outbreak, for within the last four days the itching has been violent.

28th.—The itching has been steadily augmenting from day to day, although until to-day nothing appeared on the skin. A slight papulo-vesicular eruption, indistinctly defined, with irregularly shaped, small, flat, pale-red disseminated, but aggregated lesions, has here and there, over the back, arms, and thighs, made its appearance. The lesions are so scratched that their features can scarcely be determined; the itching, he states, is indescribably intense, and out of all proportion to the amount of eruption. Strong alkaline baths have been used, but without relief.

March 6.—There has been but little new eruption since the last note, the few lesions that have appeared being, as the others in the present attack, abortive papulo-vesicles. The itching has continued, and the patient is suffering considerably; he is in expectation of more eruption, when, in the light of former experience, he looks forward to comparative relief.

22d.—The condition has scarcely changed within the fortnight. The itching and the "pricking, picking sensations," have been intolerable, especially over the trunk, arms, and thighs. To-day new vesicular lesions, as well as papulo-vesicles, have manifested themselves about the neck and over the abdomen, back, shoulders and arms. They are numerous and scattered, or are in patches of a dozen or more. Some are raised, tensely distended, shining, irregularly rounded or angular in outline, varying in size from a pinhead to a split pea; while others are flat, and often are difficult to detect. None have any areolæ, but rise abruptly from the surrounding healthy skin.

27th.—The eruption, which threatened to become extensive last week, has again aborted. The lesions were, without exception, all scratched and lacerated almost as soon as they began to form. The itching still continues, but in a modified degree. The officinal sulphur ointment was to-day ordered, to be well rubbed into the skin twice daily.

April 3.—The sulphur ointment gave decided and prompt relief, the patient stating that no remedy that he had ever before used had acted so effectually upon the itching.

May 1.—A few scattered papulo-vesicular and vesicular lesions, accompanied with itching, have shown themselves from time to time during the month, but there have been no signs of a serious outbreak. The patient is improving, he thinks, from week to week, and eagerly looks forward to the approaching warm weather as a source of relief. It will be remembered that every year he has recovered with summer. The internal remedies, consisting mainly of arsenic, have some time since been discontinued. The patient, at his own request, has been discharged from the hospital, and has not since been heard from.

The notes, extending over a period of several years, have been given at length, because the case is very interesting, especially with reference to the "gelatinous lesions" described. At present I shall not dwell on this subject beyond stating that these lesions have likewise occurred in several other instances of dermatitis herpetiformis which have come under my notice. I believe them to be peculiar to this disease, and to constitute a hitherto undescribed form of cutaneous manifestation.

THE VALUE OF "FORCED DILATATION" OF THE ANAL SPHINCTERS IN THE CURE OF CONSTIPATION, ETC.[1]

By EDWARD M. SCHAEFFER, M.D.,
of Baltimore.

The occurrence of reflex spasms in parts more or less remote from the seat of irritation is a well-known fact, the recognition of which has been much extended of late years by the labors of Sayre, Otis, and others, in their respective departments.

In regarding the nervous derangements and actual paralysis often associated with congenital phimosis, also, the spasmodic strictures, irritable bladders, and neurasthenic disorders relieved, coincidently, with the section of urethral contractions and narrowed meatuses, *analogy* has suggested the application of this principle of cure in cases of obstinate constipation, fecal accumulation, etc., in addition to its more common, though, probably, still infrequent,

[1] Read before the Clinical Society of Maryland, Jan. 16, 1885.

employment for fissure, hemorrhoids, chronic ulcer, and spasmodic contractions of the anus.

Setting aside theory—this simple, mechanical procedure, viz , complete dilatation of the sphincter ani muscles, has been strongly advocated abroad, in France and England, and also by the late eminent author, Van Buren, of New York, as an efficient *substitute* for the knife in the above painful affections. The latter writer, in his work on "Diseases of the Rectum" (p. 93), after crediting Récamier, of Paris, with the original suggestion, describes his method as follows, preferring the use of his fingers to any mechanical instrument: "Introduce both thumbs well beyond the external sphincter, back to back; then, taking a purchase from the buttocks with the outspread fingers, carry the thumbs forcibly apart until their palmar surfaces are arrested by the ischial tuberosities. The stretching is carried far enough to paralyze the muscles temporarily, and thus annihilate their contractile power for a few days."

Allingham, in a similar work, recommends this mode of procedure most highly, and calls it, in properly selected cases, a really admirable treatment. I find also this language bearing on the special theme of my paper (*loc. cit.* p. 58, pamphlet ed.):

"Spasm of the sphincter has been said to be a cause of impaction, but I have more often thought the reverse was the case, and the impaction the cause of the spasm. I must, however, acknowledge that spasm is often the cause of the *constipation*, which is the forerunner of impaction. In impaction spasm of the sphincter always exists. I have certainly met with cases of idiopathic spasm of the sphincter, occurring for the most part in elderly, nervous, single women, and though no impaction was present, there was always more or less constipation."

My attention was first directed to this subject in the practice of Prof. Alan P. Smith, who has, for several years, found sphincter dilatation most serviceable in conditions of anal spasm, hemorrhoids, fecal impaction, etc. I am, therefore, largely indebted to him for any suggestions here advanced, and also for the privilege of adding three cases to my own report.

Case I. is that of a young lady, 24 years of age; nervous temperament; out of health for about *nine* years with the following symptoms: constant headache and nausea, giddiness and fainting spells, great nervousness, irregular heart action; also, a muddy complexion with persistent *acne* of entire face and shoulders.

During this long period (under homœopathic observation), thanks to the suggestion of a friend, some relief was interspersed by the use of hunyadi water. Horseback riding was also resorted to with slight benefit. Whilst attending other members of the family, my aid was first sought in regard to the very disfiguring acne. The patient stated, on inquiry, that the bowels were *moved* regularly every day. Attention to the digestive and menstrual functions availed but little. Local applications to the eruption were only palliative. The use of prepared clay dressings was, however, markedly beneficial. After a month or two of this temporizing, the patient asked, one day, for a strong purgative, as she "felt so choked up she could hardly breathe." She was given a pill, containing, resin podophylli, half a grain, ext. nuc. vomic, and hyoscyamus. This produced several bilious evacuations, accompanying small scybala about the size of a marrow-fat pea; no sense of relief.

Finally the abdomen was examined, and a hardened mass found, plugging up the ascending colon, and extending half way across the transverse. The cæcum was tympanitic, and sensitive to pressure. Castor oil was given freely, and deep injections of soap-suds and water, with ox-gall, administered by the nurse. With the aid of a rectal tube I filled the bowel myself, afterwards, as high up as I could. There was no rectal impaction, but the sphincter grasped the injection tube so tightly that it could not be passed in further than six or seven inches. None of these measures sufficed; the purgatives and enemata gave only liquid passages, while a few small pellets escaped (evidently through a central lumen in the mass). Complete dilatation of the sphincters was then resorted to (October 21, 1884) under chloroform, and followed by insertion of same rectal tube to the extent of nearly two feet, with another full injection.

This settled matters, or rather unsettled them. For a week or more the patient had two or three movements each day, passing large quantities of balls, lumps, and chip-like pieces. Some of the balls were found to contain seeds resembling those of the cucumber and tomato. There was no straining necessary at any time after the operation.

It is interesting to note that the acne of years quite disappeared within two days; and the patient's commentary on the proceeding was, that it had made a new woman of her. The bowel is gradually recovering tone, after its long distention, and acting regularly, under the occasional stimulus of aloes and iron. All nausea, etc., which was invariably severe at each menstrual crisis, has ceased. The instrument employed was the familiar three-bladed anal speculum, screwed up rapidly to its fullest extent.

Case II.—W. B., policeman, æt. 51, a patient of Dr. Getz (to whose courtesy I owe a visit to the case, and also this report), suffered greatly from rectal tenesmus. Cathartics failed to empty the bowel, while the calls to stool came on every few minutes, with straining that was terrible even to witness. About a teaspoonful of mucus, fecal-stained, was usually expelled. To digital examination, the parts were apparently in normal condition.

Dr. Smith was consulted, and advised dilatation for the relief of the tenesmus. Chloroform was given, the three-bladed speculum inserted, and screwed up to its fullest expansion (larger than my wrist), a fecal impaction spooned away, and the presence of numerous superficial ulcers about the region of the internal sphincter ascertained. Some of these were nicked with a bistoury, and the dilatation afterwards repeated; but, during the evacuation of the impacted matter, and for six months subsequently—*i. e.*, until his death, all the actions were free from pain, and easily effected; the relief of the tenesmus being, practically, instantaneous and perfect.

Dr. Smith's cases were, in brief, as follows:

Case III.—An old lady, æt. 50, sufferer for three years from spasmodic anal contraction and constipation; was "dilated;" passed three potfuls of impacted matter, and returned in a week or two, dilating freely herself on an entire cure.

Case IV.—Another case was that of a sailor, troubled with hemorrhoids and obstinate constipation, due to an impaction high up in the bowel, who was similarly treated, with complete satisfaction.

Case V.—R., professional gambler; passed small, flattened stools; had fissure, piles, and chronic constipation; all of which succumbed to full dilatation.

MEDICAL PROGRESS.

Operation for Abdominal Aneurism.—Prof. Loreta a short time since operated on an abdominal aneurism by first puncturing it with a Pravaz needle and introducing through the canal of the needle a silvered copper wire. The movement of the wire caused coagulation to take place in the aneurismal sac—and the operation resulted so favorably that at the end of fifteen days the patient was in excellent condition and a complete cure was ultimately effected.—*Gazetta degli Ospitali*, Jan. 14, 1885.

The Value of Alterations of the Kidneys, Consecutive to Uterine Fibroma, as an Indication for Hysterotomy.—Dr. S. Pozzi, in the *Annales de Gynécologie*, reaches the following conclusions as to the operation above referred to:

1. Compression of the bladder and ureters is a frequent complication of uterine fibroma, even when the tumor is small, and may cause rapid and serious changes in the kidneys (hydronephrosis, cystitis, sclerosis).

2. Compression, when exerted upon the bladder, is easily recognized; not so easily, if exerted upon the ureters. Very frequently there is no suspicion of the latter until lesion of the kidneys has been produced, and change in the normal constitution of the urine (albuminuria).

3. Compression of the bladder, or of the ureters, should have great weight in influencing speedy surgical intervention, and alone may determine it.

4. In case of hydronephrosis, operative interference is particularly urgent, in consequence of the dangers which threaten the remaining kidney, which remains more or less intact. Treatment of these complex cases will be rendered less serious by operation. Hysterotomy should first be performed, and afterward the cystitis may receive attention.

5. The prognosis of hysterotomy is rendered more serious when renal alteration is diagnosticated. If it is very far advanced (confirmed Bright's), it contraindicates the operation; not so if a very slight degree of albuminuria exist.—*Journal de Médecine de Paris*, Jan. 10, 1885.

The Physiological Basis for the Theory of the Origin of Diabetes Mellitus.—E. Seegen (in the *Zeitschr. f. klin. Med.*, Bd. 8, Heft 4), after numerous experimental observations, reaches the following conclusions relative to the function of the liver and the origin of diabetes:

1. Sugar is not (in dogs) a minimum element of the blood. It varies between 0.1 and 0.15 per cent.

2. The blood, after having passed through the liver, contains double the quantity of sugar that existed in it previous to its entering the organ.

3. The passage of the blood through the liver is very important.

4. Through the process of secretion in the liver the saccharine elements are constantly being removed by the blood.

Upon the basis afforded by these conclusions, Dr. Seegen sets forth the following considerations relative to the theory of diabetes:

1. The production of sugar in the liver is a normally physiological function.

2. The normal sugar production is one of the most important functions of tissue transformation.

3. The material for the production of sugar is furnished by the albuminates present in the food.

4. It is more than probable that, as glycogen, the so-called liver starch, has no share in the normal production of sugar.—*Deutsche med. Wochenschr.*, Jan. 1, 1885.

Resorcin as a Hypnotic.—Andeer, in the *Prager med. Wochenschrift*, No. 39, 1884, attributes a hypnotic action to resorcin. The hypnotic effects have been noticed in the treatment of gastro-colitis and in commencing phthisis with implication of the larynx. A case of traumatic tetanus is also referred to in which the drug acted not only as an anti-spasmodic, but also as a hypnotic—*Centralbl. für klin. Med.*, December 27, 1884.

Sulphide of Lime as a Remedy for Ringworm.—M. Dufan proposes the application of the following preparation to the skin as a remedy for ringworm:

Flour of sulphur	100 parts.
Slaked lime	200 "
Water	1000 "

Boil and stir from time to time. When the mass is cold, decant and keep well corked in a bottle.

Before applying the preparation the patient should take a hot bath and afterward should have it thoroughly applied to the skin. He should then be well covered and put to bed.

In benign cases the itching ceases at once. In the more rebellious forms of the disease a second application is necessary. Should irritation of the skin result, it may be relieved by an alkaline bath.—*Journal de Médecine de Paris*, January 31, 1885.

Paralysis due to Hypodermic Injection of Ether.—At a recent meeting of the Berlin Medical Society, Dr. Remak exhibited a young girl, who, after poisoning by carbonic oxide gas, had received a hypodermic injection of ether, which was followed by a partial paralysis of the arm in which the injection was made. Dr. Remak held the opinion that the paralysis was not due to the carbonic oxide nor to a traumatic lesion of the nerve; but simply to the action of the

ether, and referred to the cases to which, in a former number, THE MEDICAL NEWS has already called the attention of its readers.—*Allgemein. Wien. med. Zeitung*, January 13, 1885.

A CASE OF CÆSAREAN SECTION.—On Dec. 30, 1884, DR. DOLAN, at the Halifax Union Infirmary, performed the operation of Cæsarean section on a primipara, aged 26, a pianist, whose height was only three feet eleven inches. She had been in labor five hours. There was great pelvic deformity, the antero-posterior diameter being one inch and a half. Carbolized catgut was used for the uterine wound, silver wire for the abdominal walls. The child was living. The patient died in fifty-four hours.

A post-mortem examination was held seventeen hours after death. The uterine wound was found open, a large clot having been forced through it, owing to the occurrence of vomiting. There was peritonitis, which was the probable cause of death.—*Lancet*, Jan. 24. 1885.

REMOVAL OF A PAROVARIAN CYST.—PROF. CECI, a short time since, performed successfully the very difficult operation of removing a cyst of the parovarium. It was unilocular and contained about forty-three pints of fluid, and was adherent through an anterior peritonitis, which had completely abolished the peritoneal cavity. He carefully separated the tumor from its intestinal attachments, and from the great vessels of the pelvis, and the necessarily numerous ligatures prolonged the operation through three hours.

Very little blood was lost; at the lower end of the abdominal suture four drainage-tubes were introduced. The condition of the patient was almost apyretic. On the eighth day the dressings were removed, and, complete union having taken place, the drainage-tubes were removed and the patient was completely cured. The extreme gravity of the case—not taking into account the size of the tumor, which was considerable—the difficulty of detaching it, the danger of strain and contusion of the abdominal viscera, the great length of time the operation lasted and the rapid recovery render the case remarkable.—*Gazetta degli Ospitali*, Jan. 7. 1885.

DANGER OF INJECTIONS OF TINCTURE OF IODINE REPEATED AT SHORT INTERVALS, IN THE TREATMENT OF HYDROCELE.—M. TILLAUX, in his service at the Hospital Beaujon, cautions against the danger of hastily repeating the injection of the tincture of iodine in hydrocele already injected. Six weeks are required before the results of the first injection can be determined. The danger lies in producing a false membrane which bleeds on the slightest provocation, and forming a hæmatocele, destroys the testicle. A patient 60 years of age who had been thus unfortunate, was exhibited. For two years he had had a left-sided hydrocele. Fifteen days after the first injection of iodine his physician had made a second and stronger one, with the result of producing a hæmatocele.

As to treatment: in a young subject a drainage-tube should be introduced, if decortication is impossible, as a possible means of preserving the testicle, even at a risk of long-continued suppuration; but in the old, if it be impossible to remove the false membranes—castration should be performed and the danger of an open wound thus obviated.—*L'Abeille Médicale*, Jan. 12, 1885.

NEEDLE FOUND IN THE RIGHT HEART.—DR. LEUBUSCHERE reports the discovery of a needle in the heart of a woman, aged 74 years. She died of cancer of the breast, and at the post-mortem a foreign body was discovered in the right ventricular septum, near the orifice of the pulmonary artery. Its presence was revealed by a slight prominence covered by thickened endocardium. Incision brought to view a long round iron body, uneven and brittle, owing to oxidation. It was completely encapsulated in a fibrous sheath. No trace could be found of its point of entrance. A consideration of the circumstances justified the conclusion that the foreign body for a long time had occupied its position in the heart wall, and had become harmless by encapsulation.—*Centralbl. für klin. Med.*, Jan. 31, 1885.

COCAINE IN RECTAL SURGERY.—On January 27th, at the West London Hospital, Mr. Swinford Edwards ligatured six large hemorrhoids in a woman aged fifty. As she was the subject of aortic disease, it was decided not to administer an anæsthetic. One minim of a four per cent. solution of cocaine was therefore injected into each pile at the muco-cutaneous junction, after which the entire surface of the mucous membrane at the lower part of the rectum was painted over with a like solution. The operation, which lasted twelve minutes, was almost painless, the patient only slightly feeling the last incision. Twenty-five minims of the solution of cocaine were used in all.—*Lancet*, Jan. 31, 1885.

EXTIRPATION OF A PAPILLARY ADENOMA OF THE BLADDER BY INCISION THROUGH THE VAGINA.—KALTENBACH, in the *Archiv f. klin. Chir.*, Bd. xxx. Heft 3, 1884, reports a case of a woman who for two years was affected with hæmaturia. Dilatation of the urethra revealed a tumor the size of a walnut on the anterior wall of the bladder. Dr. Kaltenbach made an incision an inch and a half long in the vesico-vaginal septum, and removed the tumor by the aid of the bistoury, scissors, and Paquelin cautery, after he had ligatured its base with several silk threads. The vaginal wound was closed by eight wire sutures. The ligature left in the bladder escaped through the urethra in fourteen days, and the patient was completely cured.

THE PARENCHYMATOUS INJECTION OF ARSENIC IN GOITRE.—DR. F. DUMONT, in *Correspondenzbl. f. Schweiz Aertzte*, No. 9, 1884, reports the use of injections of Fowler's solution in twenty-six cases of goitre. In one case, two and a half drachms of the undilute solution were injected. There occurred once, as a result of this injection, serious collapse, and generally, the effects were of little importance. In colloid bronchocele no results were manifest. Of three cases of cyst, in two so great inflammation supervened that excision became necessary, in one there was marked diminution. In one case of hyperplasia diminution followed; in colloid hyperplasia there was improvement, and in follicular bronchocele no results were obtained.—*Fortschritte der Medicin*, February, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
NOS. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, MARCH 7, 1885.

SUPRAVAGINAL HYSTERECTOMY AND OVARIOSALPINGECTOMY IN UTERINE MYOMA.

IN the *British Medical Journal* for January 31, 1885, DR. THOMAS KEITH gives a table of 13 complete supravaginal hysterectomies done by him in 1884. Adding to these the 25 cases previously reported, his 38 operations indicate 35 recoveries and 3 deaths, or a mortality of only 7.89 per cent., which is the best result ever attained by any surgeon.

It is to be regretted that in this, as in his first, paper, Dr. Keith has not given the details of his operative procedures. In the majority of his first 25 cases, the operation was extraperitoneal, the stump having been secured outside of the belly by a large clamp. The broad ligaments were almost always separated off the tumor and tied separately, being sometimes left inside and sometimes secured outside. The bladder was left full, in order that its edges might be readily recognized, and in six cases the viscus was dissected off the uterus, and great enucleation was often required in order that the serre-nœud might be applied as low down as possible. He now states that every case must be a law unto itself in dealing with the attachments of the tumor. A few of the simpler cases may be treated extraperitoneally. The broad ligaments must generally be left inside. Sometimes the treatment may be entirely intraperitoneal by means of Kœberlé's serre-nœud, or it may be half intra- and half extraperitoneal, the latter demanding much subsequent care, although the period of convalescence is much shorter than when the entire stump is left outside He thinks that the future of the operation will depend upon the perfecting of the intraperitoneal mode of managing the stump, and is hopeful that the cautery will be found the best and safest treatment. As in ovariotomy, he long since abandoned the use of the carbolic spray during these operations. In only 6 of the 38 was it employed, and 1 of these perished. Of the 32 done without the spray, 2 died of exhaustion.

In view of the extraordinary success attained by Keith, we may be considered impertinent in questioning his methods of operating; but we are convinced that the extraperitoneal mode of dealing with the stump affords far better protection against hemorrhage and sepsis than does the intraperitoneal treatment. Since the former has been adopted, results have greatly improved, as is shown, indeed, by Keith's own cases, in the majority of which it was employed, as well as by the experience of other operators. Thus, of 99 cases from the practice of Tait, Bantock, Thornton, Kasprzik, Koltenbach, Terrier, Queirel, and Howitz, of which we happen to have notes, 20, or 20.2 per cent., perished, while of 46 examples of the intraperitoneal method from the practice of Tait, Bantock, Thornton, Kuester, and Olshausen, 29, or 63.02 per cent., perished. It is, of course, possible that future improvements in the intraperitoneal method may greatly reduce the risks of complete extirpation of the uterus; but the majority of operators at present prefer securing the stump outside of the belly, and the wisdom of their choice is attested by the statistics which we have just given.

The results of complete supravaginal hysterectomy vary greatly in the hands of different operators, and it is interesting to compare the success attained by some of the more prominent surgeons of Great Britain. Thus, Tait has had 54 cases, with 35 recoveries and 19 deaths, or a mortality of 35.18 per cent.; Keith, 38 cases, with 35 recoveries and 3 deaths, or a mortality of 7.89 per cent.; Savage, 17 cases, with 13 recoveries and 4 deaths, or a mortality of 23.52 per cent.; Bantock, 14 cases, with 11 recoveries and 3 deaths, or a mortality of 21.44 per cent.; and Thornton, 12 cases, with 7 recoveries and 5 deaths, or a mortality of 41.66 per cent. The entire number, 135, indicates 101 recoveries and 34 deaths, or a mortality of 25.18 per cent. Just why such marked differences in the death-rate should exist it is impossible to state, since all of these operators have a large experience in abdominal surgery. Mr. Thornton maintains that "it is to the perfecting of our antiseptic precautions that we must look for improved results;" while Mr. Savage advises a "drainage-tube being placed above the clamp, if there be the least reason to expect oozing downwards into the pelvis." These precautions were not observed by the majority of the operators that we have mentioned; and, strange to say, the best results have followed in the very cases in which they have not

been employed. Thus, without Listerism, Keith lost only one out of every sixteen, while Thornton, with Listerism, lost nearly one-half of his patients. If we were to base an opinion upon these data, we would be right in stating that strict antiseptic precautions were a drawback instead of an advantage; but it is manifestly wrong to lay the blame upon the omission or observance of a single detail in the technical method of operating. We, ourselves, believe that future success will depend upon the further development of the technical method, and, in the meanwhile, we cannot too urgently insist upon the importance of clean fingers, instruments, sponges, ligatures, and sutures, the prevention and thorough arrest of hemorrhage, a clean and dry peritoneum, and the extraperitoneal treatment of the stump.

Although, as we have seen, Keith is an eminently successful hysterectomist, he shows a proper conservatism, operating only in extreme cases in which life is rendered useless. The tumors were generally large, the patients were more or less broken-down by pain and hemorrhages, not a single one having been in good health or in good condition, and not a single pedunculated neoplasm was interfered with. In examples of small myomata, or those weighing less than nine pounds, he resorts to removal of the ovaries, and in the twelve cases in which he practised that operation more or less benefit resulted, menstruation, however, continuing in one in consequence of a fragment of ovarian structure closely adherent to the tumor having been left behind.

The removal of the ovaries, as is well known to those who have had experience with the operation, is not always so simple a procedure as the unexperienced surgeon might imagine. Thus, in nine of the hysterectomies of Keith, the operation was begun for the purpose of removing the ovaries only; but they were either not found, or, if found, they could not be excised. In one case, indeed, the silk ligature cut the ovary clean off, leaving a hole in the side of the uterus, the hemorrhage from which could only be controlled by removal of the tumor.

Despite the difficulties which now and then attend oöphorectomy, that operation—or, still better, removal of the appendages—should be performed for the arrest of the growth of uterine myoma as soon as symptoms draw attention to the disease, with the view of restricting the grave operation of hysterectomy to the small group of cases in which life is threatened, and the lesser procedures are impracticable. The recent statistics of Wiedow, published in the *Archiv für Gynækologie*, Bd. xxiv. Heft 2, show that of 112 cases of oöphorectomy derived from all sources, 17, or 15.18 per cent., perished, mostly from sepsis. In 73 in which the result was known, the bleeding ceased and the menses were arrested in 53, and there was simultaneous diminution in the size of the tumor in 36. These results are not very satisfactory; and the fact has been established that removal of the ovaries alone does not always effect the menopause or stop the growth of the tumor.

For these reasons, Tait recommends the removal of the appendages in the class of cases under consideration, in which he is supported by Thornton and Savage. Of 139 cases in the hands of these surgeons, 132 recovered and 7, or 5 per cent., died; Tait having lost 7 out of 99 cases, while Thornton's 15 and Savage's 25 cases were successful. Of 81 supravaginal hysterectomies, on the other hand, performed by the same operators, 27, or 33 per cent., perished, thereby establishing the more formidable nature of the latter procedure. Just how satisfactory the removal of the appendages has been, we are unable to say; but the cases operated on by Tait up to July, 1883, show that the results left nothing to be desired. The procedure certainly has a great future before it in myomata which prove troublesome from hemorrhage and pain before they attain a volume which might demand the more dangerous operation.

HÆMATOCELE AFTER REMOVAL OF THE APPENDAGES.

In connection with the question of removal of the appendages for uterine myoma, we may call attention to Mr. Tait's experience with that operation for inflammatory disease of the appendages. Of his 201 cases, 10, or 5 per cent., perished. In the majority, relief was complete and immediate; but he cannot speak precisely of the absolute effects of the operation, because a sufficient time had not elapsed in very many of the cases.

In 13 cases, however, for a period varying from six months to two years, little or no relief was obtained, and in every one of these the cause of failure was the formation of a hæmatocele, generally within a week after the operation. In some it was clearly localized on one side, while in others the effusion uniformly surrounded the uterus. In every case, the pulse and temperature went up, there was much pain, and the patient remained an invalid. In one patient, the effusion having suppurated, Mr. Tait reopened the belly about four months after the original operation, and cleaned out a small quantity of pus, with the result of affording complete and immediate relief.

The accident described by Mr. Tait has been met with by Mr. Savage, who briefly notices it in the *British Medical Journal* for January 31, 1885, in which number Mr. Tait's paper may also be found. In two cases, in the third week after the removal of the appendages, a second laparotomy was made, blood and pus evacuated, and a drainage-tube inserted. Both patients recovered, although the symp-

toms indicated a fatal issue before the belly was opened.

The occurrence of these hæmatoceles is most puzzling; but they constitute an important cause of failure after the removal of the appendages, and we are indebted to Mr. Tait for having recognized and called attention to them.

GENERAL GRANT'S CONDITION.

The very grave character of the disease with which General Grant has been afflicted since last August has been fully appreciated by those connected with him by domestic and professional ties, but, for reasons that can be readily imagined, their fears and convictions have not, hitherto, been publicly expressed.

The first symptom of his present distressing affection was persistent pain at the back of the tongue, and it manifested itself last August while the General was at Long Branch. He was urged by Dr. DaCosta, who was asked to look at the tongue, while making a social call upon the General, to lose no time in consulting his family physician, Dr. Barker, but, as a slight improvement followed, this advice was not acted upon until after the lapse of several weeks.

When the General returned to New York in the beginning of October, there was upon the right side of the tongue opposite the tonsil an ill-conditioned ulcer, which, at times, was very painful. He was at once placed by Dr. Barker under the care of Dr. J. H. Douglas, under whose treatment the pain grew less, and the ulcer showed a tendency, slow and intermittent, but still progressive, to heal. During the latter part of November and the most of December, the pain in speaking and swallowing was very great. At about the same time he entirely abandoned the use of tobacco and had several defective teeth drawn, in the hope of thereby diminishing the pain and hastening cicatrization.

Within the last two weeks the disease has progressed very rapidly, and has destroyed the right anterior pillar of the fauces; it occupies also the anterior portion of the right tonsil and the contiguous portion of the tongue in the form of an ulcerated induration. There is also some glandular enlargement in the neck. The edges and base of the ulcer are indurated, and microscopical examination of fragments removed from it show groups of cells characteristic of epithelioma.

The general condition of the patient has suffered, and he is anæmic and thin. Although the General suffers greatly at times, he has many intervals of relief in complete freedom from pain. He is cheerful, although fully aware of his condition, and actively occupies himself in the preparation of his military memoirs.

As the disease is steadily progressing, and has involved the tonsil and fauces on the right side, as well as the contiguous base of the tongue, there can be no question as to the inadvisability of attempting operative interference.

Our readers will share with us the deep regret with which we have learned that the days of General Grant are numbered. There is something infinitely touching in the patient heroism with which the General endures his cureless suffering. Propped up on pillows, he is described as working steadily upon the history of his military life which he is anxious to complete before he is called away. We are sure that everywhere throughout the land, South as well as North, there will be heartfelt sympathy with the troubled ending of a career which but a year ago seemed so brilliant. The magnanimity which he displayed in the hour of victory has won for him a sure place in the hearts of all his countrymen.

Our regret at this unwelcome intelligence is the severer as it was wholly unexpected, since the *Medical Record* only a fortnight ago stated, as if by authority, "that all fears of grave complications are for the present at an end." Subsequent to the date of the microscopic examination of the diseased tissue, which proved it to be malignant, the *Medical Record* assured us, in the same article which was furnished in advance to the Associated Press, and thus disseminated throughout the land, "that all the more serious and alarming symptoms connected with the tongue and throat have entirely disappeared." Our contemporary owes to the public and to the profession an explanation of this misinformation, for which we observe that Dr. Douglas disclaims all responsibility.

THE NEW BUILDING FOR THE ARMY MEDICAL MUSEUM AND LIBRARY.

We take very great pleasure in announcing that the Senate has passed without amendment the House bill providing for the erection of a fire-proof building to be used for the safe keeping of the records, library, and museum of the Surgeon General's Office of the Army. This measure has been for the last four or five years persistently urged upon Congress by the medical profession of the country, and its final success is extremely gratifying.

At one time it seemed as if the bill would fail, owing to disagreement between the House and Senate as to the location of the building, but this was happily averted, and in accepting the House Bill the Senate has acted wisely.

The Act provides that the building is to be constructed on the government reservation in Washington, in the vicinity of the National Museum and the Smithsonian Institution, the precise site to be selected by a commission composed of the Secretary of War, the Architect of the Capitol, and the Secretary of the Smithsonian Institution. It is to be in accordance with plans and specifications submitted by the Surgeon-General of the Army and approved by the above-named commission, and to cost not more than two hundred thousand dollars, and is to be built under the direction of the Secretary of War. The sketch plans originally prepared for this were for a central building, 114 by 48 feet, and two wings at right angles to this, each 126 by 60 feet. One of these wings is to contain the library and the other the museum, the central building being occupied by offices and records. Some modification of these plans will be necessary, as the estimate to complete them was two hundred and fifty thousand dollars, while but two hundred thousand were granted. The building is to be of brick, very plain and simple in style, but thoroughly fire-proof.

As soon as the incoming Secretary of War is ready to attend to business, this will be one of the first matters to claim his attention, and it is hoped that the building will be completed and occupied by the time the International Medical Congress meets, in 1887, when it will be one of the most interesting features of the place to our foreign guests.

A very large majority in both Houses of Congress were in favor of the passage of this act, and among so many it is hard to particularize, but the thanks of the profession are especially due to Representatives John F. Follett, of Ohio; Theodore Lyman, of Massachusetts; S. M. Stockslager and W. S. Holman, of Indiana, and to Senator J. R. Hawley, of Connecticut, for the manner in which the bill was managed in the crush of business, during the last days of the session, which threatened to overwhelm it.

COMMON SENSE AS TO VIVISECTION.

BOTH in reformers and legislators common sense is eminently a desirable characteristic. The exaggerated, and in many cases absolutely false, statements of the antivivisectionists have led many benevolent persons to believe that vivisection consists in the deliberate "cutting up" of living dogs and other animals piecemeal until not enough is left to live. The medical profession, with the exception of a few abnormal minds, know that the fact is that many of the experiments are of the simplest character, others are comparatively slight operations, and a few of a severe character—the last two nearly always done under anæsthetics. Doctors do not delight in cruelty. In fact, the followers of no other occupation are so constantly and conspicuously humane.

We are glad to see that this rational view of vivisection experiments in medicine has received in Germany official sanction.

Herr von Gossler, the Minister of Public Instruction, has just issued a decree to all the medical faculties of Prussia, announcing that official reports have fully convinced him that at the universities, the scientific experiments practised upon living animals are made with a due regard to both science and the dictates of humanity—this, too, in a country that has been attacked most fiercely by the antivivisectionists.

The regulations which he has promulgated are eminently the dictates of common sense. He decrees as follows: 1, Experiments with live animals are only admissible for purposes of scientific investigation or instructive demonstration; 2, at lectures these experiments are allowed only in so far as they may be required for a full understanding of the instruction imparted at such lectures; 3, the preparations for experiments at lectures are, as a rule, to be made previous to actual demonstration, and in the absence of the students; 4, the experiments shall only be made by professors or teachers, or under their special supervision and responsibility; 5, experiments which, without detriment to the result, can be made on animals of a lower order shall only be practised on such, and not on more valuable animals; and, 6, in all cases in which it is not absolutely incompatible with the end and aim of the experiment, the animals must previously be anæsthetized.

If our friends opposed to vivisection are in earnest in their efforts to protect animals from cruelty, and yet not inflict cruelty upon both man and animals by obstructing the humane progress of medical science, they would consent to a law embodying such reasonable restrictions as are here outlined.

We have no doubt that the most earnest and active friends of medical progress, here or elsewhere, would willingly join them in obtaining such a law.

WE understand that an unfortunate man afflicted with hypospadias has been exhibiting himself under the name of "Madame Duplex de Balzac," in a house on North Eleventh Street in this city, and that he sent out circulars inviting those interested in "science" to call and examine him. Of course such a case possesses no novelty for physicians, and the "scientists" who pay for admission will be principally the fast men about town. For decency's sake, we are glad to learn that this exhibition of "Madame Duplex's" genito-urinary organs has been stopped by the police.

REVIEWS.

Intestinal Obstruction, its Varieties, with their Pathology, Diagnosis, and Treatment. The Jacksonian Prize Essay of the Royal College of Surgeons of England, 1883. By Frederick Treves, F.R.C.S., Surgeon to, and Lecturer on Anatomy at, the London Hospital; Hunterian Professor of Anatomy at the Royal College of Surgeons of England. With 60 illustrations. 12mo. pp. 575. Philadelphia: Henry C. Lea's Son & Co., 1884.

This little book, one of the series of clinical manuals for practitioners and students of medicine, is just such a work as every physician should read over during his first leisure evening, and then keep on an upper shelf of his library for immediate reference, at any time when a case of bowel obstruction occurs in his practice. The extent of our medical literature is now so vast, that only phenomenal minds can attempt to grasp, still less to hold fast to, all the details of its various subjects. Hence, for an ordinary practitioner the only available method is, to supply himself with the best and most recent treatises on the rarer forms of disease, and diligently consult them in turn, as emergency may require, for the special knowledge they are able to furnish.

The importance of the subject of intestinal obstruction is shown by the fact, that over two thousand persons die in England alone, every year, from obstruction of the bowels exclusive of hernia. The classification of the various forms is made on pathological grounds, because our knowledge of the morbid anatomy is so much more complete than the clinical history. The illustrations are nearly all original, and as a general rule excellent, considering how difficult it is to represent clearly such a convoluted object as a knot in the intestines, or an ileo-cæcal intussusception. In his valuable chapter on the treatment, our author devotes several pages to a consideration of the use of opium, which he pronounces of more use than any other drug, not only for allaying pain, mitigating spasm and shock, but even in some cases sufficing to cure the disease. On account, however, of the power which this narcotic possesses of obscuring the symptoms, a judicious caution is urged in its employment until after a definite diagnosis has been made, or a definite plan of treatment decided upon. The dangerous effects of the administration of aperients in cases of intestinal obstruction are especially insisted on, the use of ice, electricity, and massage is guardedly recommended, and copious enemata or insufflation by Lund's inflator are heartily approved in suitable cases. Of the operative procedures laparotomy is declared to be the most important, and likely in the future to occupy a still more conspicuous position than it does at present. A median incision is advised, and the hand being introduced into the cavity of the abdomen, the cæcum should be searched for, and examined, as a guide to the seat of trouble, which is to be relieved, if possible, according to subsequent rules. The entire operation is expected to be performed under the strictest antiseptic precautions, for it would certainly appear that laparotomy has been attended with greater success since the introduction of Listerism. In a series of one hundred and twenty-two cases of laparotomy for intestinal obstruction, exclusive of intussusception, collected by the author, the number of deaths was seventy-seven, a mortality of about sixty-three per cent. Mr. Treves, however, shrewdly observes that there is no doubt the death-rate after laparotomy is a very great deal higher than that shown by this table, for probably the recorded cases bear to those that are unpublished the proportion of one to ten, "and it may be surmised that the great bulk of these unpublished cases ended in death."

SOCIETY PROCEEDINGS.

NEW YORK STATE MEDICAL ASSOCIATION.

Fifth District Branch.

Scientific Meeting, held at the Clarendon Hotel, Brooklyn, February 25, 1885.

The President, J. C. Hutchison, M.D., in the Chair.

Dr. Hutchison, in opening the meeting, spoke as follows:

Gentlemen: By virtue of my position as one of the Vice-Presidents of the New York State Medical Association, and as President of the Fifth District Branch Association, I call you to order and bid you welcome. This, as you know, is our initial meeting, and it is desirable that we should start right on the professional road open before us. The Branch Association of the State Association of which we form a part, includes in its area Dutchess, Putnam, Westchester, Ulster, Sullivan, Rockland, New York, Richmond, Suffolk, James, and Kings Counties. The desire of the friends of medicine represented by this Branch is ultimately to arrange for frequent meetings of the Fellows in this and other counties of the district.

It is entirely easy for physicians to enter our fellowship. All who become members of the State Association are by virtue of that relation members of this Branch Association. Such is the manifest value of a union of action, where there is union of interests, that all who, in the profession, are in sympathy with us should join the State Association and thereby become members of this Branch Association. The success of the State Association has been remarkable. There were more than five hundred and fifty members who joined in the first year of its existence, and the accessions are large and constant.

Still, I desire to say that mere numbers is not the object; the aim is to get the best material for effective and congenial work on behalf of the best interests of the profession and of the public. One of the great features is freedom from legal control or complications. The Association wants nothing to do with the Legislature or any other political body. It desires to be free to admit or reject whom it pleases. At all times ready to give information when requested to the civil authorities, executive, legislative, or judicial, it still wishes no official connection with them; for medicine is a voluntary, self-independent profession, governed by its own rules.

At the same time, toward all our brethren of a like faith, but of a different policy, we all, I know, would have only the kindest feeling. Men of culture and honor can differ without anger or loss of mutual self-

respect. I am persuaded that as our Branch Association completes the initial work of organization and engages in the professional objects and deals with the subjects germain to our calling, our union will be found pleasant and profitable, and one crowned with the approbation of our consciences and with beneficial results to humanity, to science, and to ourselves.

DR. J. W. S. GOULEY, of New York, read some

NOTES ON CONTRACTURE OF THE BLADDER, CONSEQUENT ON CYSTITIS.

They consisted of a series of cases, occurring in both males and females, of a kind which, from the suffering they entailed and the evil consequences arising from their neglect or improper treatment, he thought were well worthy the attention of the profession. The term *contracture* was taken from the French, and best expressed the condition of the bladder to which he referred. This contracture might be general or limited to a portion of the viscus. Its existence was often not discovered until the difficulty had become irremediable; but if taken in hand early, such cases could usually be cured, or, at all events, treated to such advantage that permanent relief would be afforded.

Among the causes, which included everything that might occasion a difference in the character or quantity of the urine, were mentioned stone and foreign bodies in the bladder, papillomata of the mucous membrane, urethritis, hypertrophy of the prostate gland, disease of the nervous centres, displacements of the uterus, anæsthesia by ether, too frequent or careless catheterization, and fecal accumulations. Hysterical women and men of nervous temperament frequently suffered from cystitis. In them polyuria was common, and, if this continued unchecked, it would be pretty sure to give rise to vesical trouble. The quantity of urine passed would soon become diminished with each act of urination; but the desire to urinate would constantly increase, and violent contractions of the bladder would result. The urine would contain a large amount of vesical epithelium, and the mucous membrane of the bladder would become "water-logged." In consequence of the irritation excited, permanent contracture was liable to result. On the other hand, the opposite extreme from polyuria, in which the specific gravity was low, viz., a condition of the urine in which the specific gravity is very high, such as was met with in diabetes mellitus, would also give rise to cystitis and contracture of the bladder. He did not mean to say that cystitis occurred in all cases of diabetes; but he thought it could not be denied that it was of very frequent occurrence in this affection. How was it, then, that the same effects were produced in the bladder by urine of both a low and a high specific gravity? The explanation was that when the urine was of low specific gravity, the epithelial cells of the vesical mucous membrane became swollen by an endosmotic process, died, and were cast away, while when it was of high specific gravity, the epithelial cells by an exosmotic process shrivelled, and then died and were cast away. The final result being in either case the same, the denuded mucous membrane suffered constant irritation from the urine in contact with it. The urine was rendered especially acrid by certain medicinal substances, such as opium, cantharides, balsams, etc.

When there was a stone or foreign body in the bladder, the walls of the latter sometimes grasped it very tightly, being kept in a tonic state of spasm by the irritation which it set up. Such a condition often deterred surgeons from performing lithotrity and induced them to resor to lithotomy instead; but this difficulty could be entirely overcome by the exercise of a little care and patience. In speaking of uterine displacements as a cause of contracture, he referred to a very severe case of the kind which he saw a number of years ago in consultation with the late Prof. George T. Elliott. Here the cystitis was occasioned by the pressure of an anteverted uterus, which had become permanently fixed by adhesions in this malposition, so that it was impossible to replace it. In a case of contracture, occurring in an old lady, which was due to the presence of urethral papillomata, the trouble was of many years standing. When she first came under observation the bladder had become diminished to a capacity of only half an ounce, but he had finally succeeded in increasing its capacity to four ounces, beyond which point he did not think it was safe to attempt to enlarge it. Acute urethritis in the male sometimes resulted in permanent contracture with sclerosis of the connective tissue of the bladder.

In prostatic obstruction, the first effect of the condition was to cause a series of violent contractions of the bladder, with the passage of only a small quantity of urine at each effort. The strangury continued week after week and month after month, until not a drop would come with the expulsive efforts. Then the contractions would cease and the bladder become overdistended with urine and overflow drop by drop, while inflammation of the enlarged lower fundus would result from the alkaline condition of the retained urine. Hypertrophy of the bladder was the almost universal rule, and one of the worst things that could possibly happen to a patient suffering from enlarged prostate would be a condition of atrophy. For himself, he had yet to see the very first instance of atrophy and atony of the bladder, which were claimed by some authorities as the usual condition in enlarged prostate. Neglected urethral stricture, as well as chronic urethritis, sometimes caused an amount of vesical contraction which finally resulted in permanent contracture.

Certain diseases and injuries of the nervous centres had been referred to among the causes of contracture. If the bladder was paralyzed, incontinence, and not retention, of urine would result. He had seen a number of autopsies in cases of fracture of the spine, and found that contracture of the bladder was present. There was also generally hypertrophy.

One of the last of the exciting causes given was the use of ether as an anæsthetic, and Dr. Gouley said this was mentioned as a warning to surgeons in the habit of employing ether for this purpose. In thirty cases out of one hundred operated on for hemorrhoids, he had found that there was contracture of the bladder, originating in the effect caused by the ether inhaled at the time of the operation. The action of this agent was twofold—first, on the kidneys, producing polyuria, and, second, on the urine, which it rendered irritable in character. There was apt to be retention of urine from tonic spasm of the neck of the bladder, and hypertrophy with chronic contracture finally resulted. To

avoid these disastrous consequences, he advised that patients about to undergo an operation should be required to urinate just before and just after taking the ether. Cystitis, being the principal factor in the production of vesical contracture, Dr. Gouley continued, was always present; and he then proceeded to give a sketch of its various symptoms.

The general treatment of contracture consisted in the use, first, of those remedies which tend to diminish pain by their influence on the nervous system, and, second, those which favorably affect the character of the urine. Opium in a few full doses was often of great service at first; but, except where there was polyuria, it had an injurious effect if kept up for any length of time. Belladonna is very useful; but unfortunately it could not be administered for more than two or three days in succession on account of its toxic effects. It could sometimes be given with advantage combined with opium. Hyoscyamus, or its alkaloid hyoscyamin, was also useful; but, like belladonna, it was impossible to keep it up but for a very short time, and for the same reason. In polyuria, opium was beneficial; but he had never attempted to persevere very long in its use for fear of engendering the opium habit in the patient. Among the other agents that he had found of service in contracture were ergot, gallic acid (in twenty-grain doses), and citrate of soda, particularly with hyoscyamus. In regard to hyoscyamin, he was aware that Dr. Squibb had objected to its use by the mouth, on the ground that it rapidly underwent decomposition in the stomach, but he had seemed to get very good results from its administration in this way. In certain cases in which there was much induration, he was in the habit of using tincture of the chloride of iron, and he usually combined this with cantharides and ergot. Strychnia or nux vomica he regarded as particularly injurious. Salicin combined with bromides was useful. No good result could ever be obtained, however, unless the rectum was kept empty.

In the young and strong, local depletion by the application of leeches to the hypogastrium and perineum is of service, but unless the patient be quite robust, the procedure is unsafe. Ordinary irrigation of the bladder is clearly contraindicated in the acute stages of cystitis. For the relief of cystitis and contracture at the same time, he strongly advocated slow and gradual hydraulic distention of the bladder, as practised by Dr. C. E. Allen; a method of treatment which had, unfortunately, been given up to a large extent at the present time. Sudden dilatation of the bladder with the aid of anæsthetics, which had been so highly lauded by some authorities, he thought, was not to be recommended, as it was apt to be followed by bad consequences. The injection of strong solutions of nitrate of silver was advised by some; but this was dangerous, and very likely to render the difficulty incurable. In cystitis, the nitrate of silver is of unquestionable value, but it should only be used only in weak solutions.

After a few days of treatment in any case, the surgeon would be able to tell how much good was to be expected from the use of gradual dilatation. For instance, if at the first sitting the capacity of the bladder was found to be only one ounce, and at the next to be half an ounce more, and if at the third sitting an additional half ounce still could be thrown into it without causing pain or irritation, there would be a good prospect of speedy relief and perhaps cure. If the urine remained purulent, it was recommended that the nitrate of silver should be employed, beginning with a solution of the strength of only one-tenth of a grain to the ounce. It was seldom necessary to use a solution of greater strength than one grain to the ounce. The injections should be repeated every four or five days. After a stone or foreign body which had given rise to cystitis had been removed, it was of the utmost importance, although it was a point that was often entirely lost sight of, that the condition of the bladder should be attended to. After lithotomy and lithotrity, it was not infrequent to see vesical contraction resulting that might, with proper care, have been avoided.

Dr. E. R. Squibb, of Brooklyn, said that he was expecting Dr. Gouley to say something more in regard to the beneficial effects of iron. Formerly the tincture of the chloride of iron was always used in the class of cases which he had described, and the good derived from it, he thought, was to be attributed not so much to the iron itself as to the muriatic ether and nitrous ether which the old tincture, particularly if it was not used for some months after its manufacture, always contained. Of late years, however, this agent had been much less used in such cases, and he believed that this was on account of the change in its character as prepared at present. This was due to the fact that the United States Pharmacopœia now insists that the nitric acid should all be driven off. The muriatic ether referred to seems to be always generated in the presence of a small quantity of nitric acid; and he thought it was because of this change in the preparation of tincture of chloride of iron that sweet spirits of ether is now so favorite a remedy in spasm of the bladder and neck of the bladder. As to the use of hyoscyamin by the mouth, he was glad to learn that it had been so successful in Dr. Gouley's hands. It was an extremely delicate alkaloid, and it seemed to him that it must be decomposed by the acid condition of the stomach. He would like to inquire whether Dr. Gouley had ever used it hypodermically. At the present time, when the old-fashioned straight-jacket had to a great extent been given up, hyoscyamin was the physiological straight-jacket of our insane asylums, and it was a fact that it is almost universally given by hypodermic injection as being the best and surest method.

Dr. Isaac E. Taylor, of New York, said that the cases which had come under his notice were principally those which were primarily due to nervous influences. There was one source of cystitis and contracture which he thought had not been alluded to in the paper—viz., ulceration of the urethra, This was generally so small in extent that it was more like a fissure, and hence it was very difficult to recognize. Vaginismus and fissure of the anus had often been treated for it. He then mentioned a striking instance of this trouble, in which the urethral ulceration escaped the attention of a large number of prominent physicians. When the patient first came under his care he supposed that she was suffering from some abnormal condition of the uterus, as there was marked vaginismus, and did not think of examining the anus or urethra. He afterwards found, however, that in the latter there was a small ulcer about one-third of an inch in diameter and not more than a

sixth of an inch in depth. As soon as this point was touched, and only then, there was a spasm of the vagina, as well as of the anus. He believed that many cases of supposed vaginismus were in reality instances of urethral ulcer. In the case he had mentioned, the patient passed a small quantity of urine about every twenty minutes, which caused her intense agony and rendered her life absolutely miserable. Dr. Taylor concluded his remarks with some reference to reflex action as concerned with the bladder.

Dr. Robert Newman, of New York, said that the paper opened up a wide scope for investigation. He agreed with Dr. Gouley that the causation could, as a rule, be readily traced, but in some cases it was very difficult, as, for instance, where it was dependent on obscure disease of the spinal cord. Another obscure source was pyelitis, which could only be definitely made out by conscientious microscopic examination of the epithelium found in the urine. In regard to the treatment, he thought this ought to be a little different in males and females. In acute cases he had found that the best local application was extract of belladonna in the form of suppositories placed in the vagina in females and in the rectum in the case of males. A large amount of the drug could be borne in this way without doing injury, as was shown by one case in his practice in which a suppository containing five grains of the extract had been used, the druggist having put five grains in one suppository, instead of into five, as he had ordered in his prescription. The case, which was an unusually severe one, was, however, at once completely relieved, and no bad results followed the large amount of belladonna used. The hydraulic employment of warm water worked very well in acute cases in males. Of internal remedies, he believed that extract of cannabis indica was better than anything else. In chronic cases in females, the washing out and dilatation of the bladder gave a great deal of relief. The use of hot water and extract of belladonna locally constituted his great reliance. Dr. Newman then referred to the impairment of innervation giving rise to partial and complete paralysis of the bladder.

Dr. Van Wyck, of Dutchess County, stated that last summer he had had in his practice three cases of cystitis which were due entirely to malarial origin, and which were treated successfully with quinine and other remedies appropriate to malarial trouble.

Dr. Rushmore, of Brooklyn, said that the general practitioner was constantly meeting with cases of irritable bladder in very young children, and thought that the correct explanation of this had been given by Dr. Gouley in speaking of polyuria. It was the effect of the large quantity of fluid, with low specific gravity. Thus it was found that simple warm water would irritate the mucous membrane of the throat and nose when inflamed; but if salt was added to the water its effect was beneficial. He then mentioned the case of an old lady who suffered from polyuria in consequence of mental anxiety, and this brought on an irritable condition of the bladder. In many of the obscure cases of vesical trouble, he thought light could be obtained by directing the attention to the kidneys.

Dr. Gouley, in answer to Dr. Squibb's question, replied that he had never as yet tried hyoscyamin hypodermically, but that he should certainly do so at the first opportunity. In regard to the tincture of chloride of iron, he had been under the impression that he had always been using the old-fashioned preparation, not having been aware of the change that had been made in its preparation. No doubt this would account for the unsatisfactory results which he had noticed in certain cases in which it was employed. He had always been in the habit of relying on the tincture of chloride of iron, and in other papers he had said he should scarcely be able to treat urinary diseases without it. He had often used the sweet spirits of nitre, but generally rather sparingly, because he thought it was not advisable to employ such irritants in cases in which the kidneys were likely to be already involved. Pyelitis was extremely common in this connection, and it took very little to give rise to severe pyonephritis in cases of chronic disease of the urinary organs. Dr. Taylor had alluded to ulceration of the urethra. The President would probably recollect that some ten years ago he had read a paper in Brooklyn (before the Kings County Society) on cystitis; and in this he had called attention to certain lesions of the female organs which had never before been mentioned. Among these were fissure and slight ulceration of the urethra. As to ulceration of the bladder itself, Dr. Gouley said he would defy any one to show him a case of it He believed that it might perhaps occur once in a vast number of cases, but he had looked for one instance of it in the dead-house for years in vain. If simple denudation of the mucous membrane were regarded as ulceration, of course this was sufficiently common; but in the denudation the trouble began and ended. Practically, true ulceration did not exist, and the only case in which there was anything like an approach to it which he had ever seen was one in which there was a mass of granulations around a button which had gotten into the bladder.

In regard to the endoscope (to which Dr. Newman had incidentally alluded), he remarked that he never used the instrument now. He had formerly resorted to it occasionally, but he found that he could get along decidedly better without it. As to paralysis of the bladder, he thought the opinion of the profession was very much mixed up. When there was paralysis, he believed that the whole bladder was paralyzed, and if so, that there must necessarily be incontinence, and not retention, of urine. He was glad that Dr. Van Wyck had referred to malaria in connection with cystitis. The explanation of their connection was very easy, for in the trouble which we called malarial fever there was invariably found lithæmia to a most pronounced extent. The uric acid in the urine irritated the bladder mechanically, and sometimes it was in such excess that uric acid calculi were formed in the kidney itself. He was also glad to find that Dr. Rushmore agreed with him as to polyuria being a frequent cause of cystitis. This is more often the case in young subjects than in the aged.

Dr. Austin Flint presented a specimen from

A CASE OF ANEURISM OF THE ARCH OF THE AORTA PRESENTING UNUSUAL DIFFICULTIES IN DIAGNOSIS.

If it had been an ordinary case, he said he would not have ventured to take up the time of the Association in calling attention to it. The patient was a gentleman 45 or 50 years of age, as well as he could remember,

and he had seen him in consultation with Drs. Speir and Little, of Brooklyn, by whose courtesy he was enabled to present the specimen on this occasion. When he saw him he had some difficulty of respiration, but this was not very marked at that time. There was, however, distinct stridor; though a careful examination with the laryngoscope by the late Dr. Elsberg had failed to detect any abnormal condition within the range of that instrument. On examining the chest, it was found that the respiratory murmur was notably feeble on both sides, and a little weaker on the left than on the right. Nothing else was discovered to show that there was any affection of the lungs. A careful examination was made for the presence of an aneurismal tumor, but none was found, and there was no pulsation disconnected with the apex-beat of the heart. There was no adventitious sound anywhere about the heart, and Dr. Flint did not satisfy himself that there was any abnormal dulness on percussion. There was no aphonia.

The probable diagnosis of aneurism was assumed from the evidence of obstruction in breathing, as shown by the stridor, and weakened respiratory murmur. There was also additional evidence of aneurism in the disappearance of the radial pulse, and the pulsation of the carotid artery on the left side during certain paroxysms, presently to be spoken of. While Dr. Flint and the other physicians were still in consultation on the case, after the examination, they were summoned to the next room to see the patient, who was then suffering from a paroxysm similar to others from which he had frequently suffered. The respiration was extremely embarrassed, the obstruction to inspiration being more marked than that to expiration, and it seemed for the time as if he was really about to die. In half an hour, however, he was relieved; although he did die in another paroxysm that occurred within thirty-six hours afterward.

It seemed pretty clear from the nature of these paroxysms that the trouble present involved the transverse portion of the arch of the aorta with the recurrent laryngeal nerve. Coming to consider the morbid appearances in connection with the symptoms during life, it was found that the whole of the ascending, transverse, and descending portions of the arch of the aorta were markedly enlarged; while there was atheroma present, with distinct calcareous flakes. Yet, what was quite remarkable, there had never been any bruit heard during life by any physician who ever made an examination of the case; and it was not at all clear why it should have been absent. It would have seemed that there were just the conditions present for the causation of a loud bellows murmur. For the absence of the radial and carotid pulse during the paroxysms, the unusual distention of the aorta, and the consequent pressure on the left subclavian and carotid arteries were sufficient to account. Finally, there was a pocket, half an inch in diameter, which protruded directly into the trachea, and must have caused, of course, more or less obstruction to respiration.

An interesting point in connection with the case was the probable causation of the paroxysms of intense dyspnœa, during one of which the patient died. It was evident that if life had been prolonged the aneurism would have made its way into the trachea, and eventually have ruptured, with a fatal issue. Dr. Flint thought there was no question that the paroxysms were due to the effect of pressure on the recurrent laryngeal nerve; but was the urgent dyspnœa the result of paralysis of this nerve, or of spasm of the glottis? Some years ago, he had reported a case in which death was probably due to spasm of the abductor muscles of the glottis; but of late, he had been led to doubt the correctness of this hypothesis, and to believe that the fatal result was due to the opposite condition, paralysis. It was more rational to suppose, he thought, that pressure on the recurrent laryngeal nerve would give rise to paralysis rather than spasm.

Another point, a recent writer had claimed that in any case, like the present, in which the obstruction was more marked in inspiration than in expiration, the difficulty was certainly due to paralysis. These paroxysms had occurred, as a rule, at times when the patient was excited in any way, as in talking earnestly or laughing heartily. A quèstion of interest, in connection with paralysis of the abductor muscles of the glottis, was, Is such a paralysis on one side sufficient to cause death? It seemed to him probable that this was not the case; but where one side was affected there was a strong liability, through some sort of sympathetic or reflex action the exact nature of which was unknown, of the paralysis becoming bilateral.

Dr. A. Flint, Jr., remarked that this case opened a field of physiological inquiry of great interest. He had often observed the effect of dividing the recurrent laryngeal nerves on the two sides successively in animals, particularly cats, while the spinal accessory nerves were left intact. When one of the recurrent laryngeal nerves had been cut, there was generally very considerable difficulty in inspiration; and when both were cut, the animal soon died. He imagined that the grasp of a hand on the throat did not cause obstruction to respiration by compression of the trachea, but rather by pressure on the recurrent laryngeal nerves, which prevented the occurrence of the movements of the larynx seen in respiration. If there had been any permanent pressure on the recurrent laryngeal in this case, he believed there would have been huskiness or some other alteration of the voice at all times; but if the pressure was occasional, such paroxysms as had been noted would be very likely to result, and he could understand from the experiments that he had made on animals how these paroxysms might be so severe as to threaten, or even actually cause death. During perfectly tranquil respiration, the larynx was almost entirely passive, there being no muscular contraction of any account required to open the glottis; but if the respiration became labored from any cause, the muscular contraction at once became very marked. Pressure on the recurrent laryngeal, it seemed to him, would be likely to cause interruption of the function of that nerve, rather than spasm.

Dr. C. A. Leale, of New York, related a case which seemed to him to illustrate well the difficulties of diagnosis in such troubles. Some years ago, a gentleman who experienced great difficulty in respiration, and in whose case a large number of competent physicians had made careful examinations without being able to arrive at any positive conclusion as to its exact nature, suddenly died. Dr. Leale made the autopsy, when it was found that there was a small aneurism of the arch

of the aorta which had ruptured into the trachea in exactly the position occupied by the pocket of the aneurismal sac in this case.

Dr. Little, of Brooklyn, who had attended the case in connection with Dr. Speir, said that the exact age of the patient was 43, and that Dr. Flint had been quite right in stating that during the paroxysms the difficulty of inspiration was greater than that of expiration. At other times, as it seemed to him, the reverse of this was true.

Dr. E. R. Squibb, of Brooklyn, read a paper on

OLEATE OF COCAINE.

The decided effect of muriate of cocaine as a local anæsthetic to mucous membrane, he said, at once suggested that it might also prove useful as a local anæsthetic to the skin. The published results of the trial of the aqueous solution for this purpose were, however, very discrepitant, and, as a rule, exceedingly unsatisfactory. The chief difficulty in its successful application seemed to be the difference between the epidermis and the epithelium of mucous membrane, and the impermeability of the former; the property of the epithelium being to promote rapid absorption, and that of the epidermis just the opposite of this. Now there was no possibility of finding a liquid which would pass through the epidermis with the same rapidity as the watery solution through the epithelium; but it had occurred to him that if a preparation could be obtained which could pass one-seventh as fast, and if it were made seven times as strong, the conditions would seem to be met for making as successful application of cocaine to the skin as to the mucous membrane at present.

Having referred to the history and applications of the pharmaceutical preparations known as oleates since their first mention by John Marshall, F.R.S., in a lecture in 1872, he said that ever since the discovery of the powerful anæsthetic action of cocaine on mucous membrane he had desired to make an oleate of it; but on account of the scarcity of the drug, he had not been able to make any experiments with this in view until the 1st of February, 1885. He then gave an account of the various steps by which he had arrived at what he believed to be the best preparation for use, viz., one containing 25 per cent. of cocaine in an excess of oleic acid; which was just about seven times the strength of the ordinary 4 per cent. aqueous solution sold in the shops. It was a very expensive preparation, costing six dollars a fluid-drachm, but it was necessary to use only a very small quantity, hardly more than a drop or two being required at a time.

Dr. Squibb next narrated a considerable number of experiments which he had employed to test the anæsthetic power of the oleate when applied to the skin. The conclusion thus reached, he regretted to say, was that the hope which had been entertained, that cocaine employed in this way might prove a useful anæsthetic for the skin, had been completely disappointed. Except for certain special applications, as to the glans penis, anus, etc., and possibly for the relief of trigminal neuralgia, in which it had not yet been tried, the oleate of cocaine had to be pronounced a useless preparation. He concluded by a few remarks in regard to the oleates in general, which he regarded as a direct combination of the ingredients employed rather than the result of a double composition, as had been widely promulgated.

The President said that he was sure that all would sympathize with him in the feeling of disappointment that the oleate of cocaine was not likely to prove of service, as had just been announced by Dr. Squibb.

Dr. Gouley related a case of excision of a fatty tumor of the thigh in which he had applied the 4 per cent. aqueous solution of cocaine to the skin ten minutes before the operation, and also injected ten minims into the tumor itself. He was disappointed in its effects, however, as the operation was by no means a painless one.

Dr. Squibb repeated, at the request of Dr. Gouley, his ideas of the physiological action of cocaine as an anæsthetic to mucous membrane, as expressed in the January number of his *Ephemeris*, according to which the local anæsthesia is probably a mechanical effect resulting from the contraction of the small vessels of the terminal bulbs of the sensitive nerves.

Dr. A. Flint, Jr., said that experiments with regard to the rate of conduction of motor nerves were very common, while those made for testing the rate of conduction of sensory nerves were quite rare. It would be exceedingly interesting, he thought, to denude sensory nerves in their course in animals, and observe the effect of the application to them of such agents as cocaine. The fibres of sensory nerves supplying the skin went either to the hair-follicles, or became united with the amorphous structure of the skin; and this might, perhaps, explain the difference of effect which cocaine had when applied to the skin from that which it had on mucous membrane.

PROPOSED SCHEME OF LIFE INSURANCE.

Dr. Gouley moved the adoption of a resolution which had been sent to him by Dr. Buckley, of the Fourth or Western Branch Association, to the effect that the Council of the New York State Medical Association should be requested to appoint a committee to take into consideration the establishment of a life insurance system in the Association, and report at the annual meeting in November. The resolution was adopted, and the Association then adjourned.

CINCINNATI ACADEMY OF MEDICINE.

Stated Meeting, February 2, 1885.

The President, W. H. Wenning, M.D., in the Chair.

Dr. J. L. Cleveland opened a discussion on

MEASLES AND ITS COMPLICATIONS,

by remarking that, although sporadic cases of measles unquestionably occur, the disease usually appears as an epidemic. This fact he illustrated by referring to the statistics of the disease in Philadelphia, as given in the text-book of Meigs and Pepper. It is there shown that during a period of ten years, there were 2279 deaths from that disease; during the next succeeding five years, no deaths were reported, and during a period of eleven years after that, there were but 100 deaths. During another period of two years, there were 200 deaths.

He passed briefly over the symptoms and course of the disease. Measles, he said, is easily recognized from its peculiar symptoms, which may be briefly summarized thus: After a period of incubation of about two weeks' duration, the affection begins simply as a bad cold, suffusion of the eyes, and a free discharge from the Schneiderian mucous membrane. Then there is a period of invasion, continuing about three or four days, in which all these symptoms continue. The disease may come on more rapidly, or it may be delayed for a longer period, even, he thought, as long as ten days, before the eruption makes its appearance.

When the eruption appears, it usually first develops on the head and neck, then upon the trunk, and, lastly, upon the extremities, requiring about forty-eight to seventy-two hours for its spread. This rule, too, has its exceptions, for the eruption may appear first upon the extremities or trunk. The fever of the stage of invasion is often acute, and it may be intermittent, or at least remittent in its character. This fever continues until the second or third day of the eruption, and then rapidly declines. The eruption usually continues from two to four days, and then fades away in the order of its appearance. After the disappearance of the eruption comes the period of desquamation, which ordinarily is of little significance.

Measles, the speaker continued, is a disease which is considered, and especially by the laity, of very little importance. It was probable that where the statistics to which he had referred indicated a total absence of the disease from the city of Philadelphia for so long a period as five years, the disease had been present, but in so mild a form as not to cause any mortality. The malignancy of measles depends upon several conditions, but chiefly upon the complications. It is unusual, and indeed rare, to have a death occur simply as a result of measles. The most frequent of the complications, and that which causes the greatest mortality, is bronchitis or pneumonia. The present epidemic which has been passing over this city, he said, is the most severe that has occurred for many years; and in his own practice, he had seen more severe cases than at any previous time. He had observed nearly all the complications of the disease that are mentioned in the books. He had lost a case or two from broncho-pneumonia; in one case, he had seen severe convulsions, but these occurred in a child that was unusually susceptible to convulsive manifestations in even slight ailments, as is usually the case where convulsions occur in the course of this disease.

He then reported a case which, he said, was unique, in that the child died from the virulence of the poison before the eruption had made its appearance. He would have been reluctant to call the case one of measles had there not been other cases of the disease in the family at the time. The symptoms were much the same as those seen in "foudroyant" cases of scarlatina, namely, high fever, suffusion of the eyes, irritation of the Schneiderian membrane, bronchial irritation, but no eruption. The speaker had seen reported cases of measles that terminated in recovery without the appearance of an eruption, but thus far he had not heard of a fatal case of that character. During the present epidemic, he had also observed a petechial eruption, but instead of this proving a serious complication as he had been taught to consider it, he had found the cases in which it occurred rather below the average in severity. Finally, he had seen a case in which there were severe complications upon the part of the kidneys. This complication, he believed, would be found more common than is usually supposed, if more care were taken to examine the urine. This patient voided urine heavily laden with albumen, and there was considerable puffiness of the lower eyelids.

Dr. F. Forchheimer remarked that he had never seen a more virulent epidemic than the present one. During the present epidemic, too, he had had illustrated better than ever before the difference in the results corresponding to the difference in the material with which he had to deal. This was especially manifested in his practice at the Hospital for Sick Children. An epidemic had broken out there soon after the disease made its appearance in the city. In this local epidemic, there had been one very interesting case, namely, one in which the disease was associated with cerebro-spinal meningitis. The child was brought to the hospital with high fever, and all the symptoms, in short, of that disease, even the petechiæ; and for this reason it was put into the general ward, in order that it might get more easily the constant attention which it required. After it had been in the house two days, another eruption was observed. This began on its face and neck. This was promptly pronounced measles, and the child was at once removed to the ward where other cases of the same disease were being treated. The autopsy verified the diagnosis of cerebro-spinal meningitis, although there was nothing to verify the diagnosis of measles. But this was soon verified in another manner. On one side of this child, when first admitted to the ward down-stairs, there lay a child with chronic hydrocephalus; on the other side, a child with phthisis. Ten days after that on which this child was admitted and placed beside them, both these children began to cough and sneeze, and both broke out with the measles. Both died of catarrhal pneumonia. In the hospital there had occurred seventeen cases, and of these, nine died. The high mortality the speaker attributed to the fact that the patients attacked in this instance were children previously debilitated by other sickness. One case had undergone a surgical operation, and the wound was still suppurating; another patient had croupous pneumonia; and still another was brought into the hospital in a moribund condition. It need hardly be added that the experience of the speaker in his private practice had not been so bad.

The occurrence of catarrhal pneumonia, he said, had been more frequent in the present epidemic than in any with which he had ever been concerned, but, as the last speaker had said, he, too, had observed nearly all the complications mentioned in the text-books. In regard to the prognosis in the petechial form of the disease, he differed from the former speaker, for he had never found it an index to a severe case; on the contrary, he looked upon the appearance of such an eruption as an indication that the case would run a rather mild course. He thought it more correct to base the prognosis upon the material with which one had to deal, rather than upon differences in the form of the disease. In no other form of exanthema have we so many cases in which the petechial eruption occurs. Its appearance

also is sometimes due to peculiarities in the subject that is attacked, and not to any difference in the form of the disease.

He differed in his opinion from the statement made by so many authors in regard to the extreme rarity of a second attack of measles. During the present epidemic, he had seen several cases of a second attack, in which he was positive of the fact, because the previous attack had been under his own observation, and there could have been no mistake. He was sure that the previous attacks had not been German or French measles, but the ordinary form of the disease.

Another peculiarity of this epidemic, he said further, is its long duration. The usual duration of an epidemic is two or three months; his first case occurred five months ago, and he is still receiving new cases. The mortality has also been above the average mortality, namely, four or five per cent. It will be impossible, however, to get a correct mortality report of the present epidemic, because many cases are reported by our Board of Health as dying from complications, without mention of the real cause. One week, for example, the report showed a mortality of but two in the entire city, when there had been more than that number of deaths in the children's hospital alone. He thought it possible that the entire absence of the disease from Philadelphia for five years might be in part due to the same cause.

DR. J. T. WHITTAKER said that it is remarkable that, although measles is the most common and widespread of all diseases, we are as yet ignorant of its cause. Numerous investigations have been made of the excretions, the exhalations, and the skin, and yet we remain unacquainted with the cause. We get the best idea of the universality of the disease from the statement of a German author, that if measles were as fatal as cholera, the human race would be extinct. The Faroe Islands, the speaker said, had been a good place to study the disease. Up to the year 1781, measles had never appeared on the islands; it was then carried there by a traveller, and nearly five-sixths of the inhabitants of the islands were attacked. The distress occasioned by such an epidemic could be easily imagined. Again in 1846, the disease appeared after an entire absence for sixty-five years, and it then attacked all the old people who had not been attacked during the previous epidemic, together with pretty much all the younger inhabitants. The isolation of these islands enabled Panum to fix the period of incubation accurately at fourteen days.

In the investigation of the cause of the disease, the speaker referred to the experiments of Home and Mayo with the skin and nasal mucus, and to those of Braidwood and Vacher, who claimed that the poison was carried chiefly by the exhaled air. They claimed that they found micrococci on glycerine-coated glass-slides, the same as they found in the lungs on post-mortem examinations, but no one has yet succeeded in cultivating the germs; and there is, therefore, no proof that they have as yet discovered the true microörganism of the disease.

The speaker had never observed a prodromatous stage of so long duration as mentioned by the reporter, and was of the opinion that this period in these cases had been confused with or made to include also the period of incubation. Four days is put down as the period of invasion, and from this fact alone we are often able to make a differential diagnosis between measles, scarlatina, and variola.

He had never observed a second attack of measles, and expressed grave doubt whether such an anomaly ever occurred. His confidence in this opinion was strengthened, he said, by the statements of the best authors and most extensive observers, who almost without exception state that a second attack never occurs. Panum, Willan, and Rosenstein state that they have never seen a second attack. He knew that if the last speaker said that he had seen a second case in the same individual, and was positive that he had treated the individual in previous attaks, there could be no question as to the truth of the statement and the correctness of the diagnosis; but the second cases which he had seen himself had all proved to be cases in which the former attack had been German measles, erythemata, roseolæ, variola, or other simple eruptions following attacks of disordered digestion.

In regard to the high mortality reported by the last speaker, approximating fifty per cent., he said that he should himself desire to look pretty closely into the sanitary condition of the institution where the cases occurred, as he thought there might be found something in addition to the complications spoken of to cause a death-rate as appalling as that of cholera.

One of the complications of measles not commonly noted, he said, is asthma. Many cases of asthma date from measles. A scientific explanation of this fact has been but recently given, in that the bronchial glands are often found enlarged, so that they may cause pressure upon the vagus nerve and thus induce the disease. This discovery would also assist in explaining the excellent results of the favorite remedy for asthma, namely, the iodide of potassium, with its well-known properties of inducing absorption in these glands.

DR. FORCHHEIMER, in reply, remarked that it is a well-known experience in public institutions of all sorts that the mortality of measles runs very high. He added, further, that the presanitary mortality which he had just reported was lower than the mortality from the same disease in other institutions of the city. There is not a public institution in the city that has not lost more cases of measles than the Children's Hospital. He admitted that sanitary surroundings have a great deal to do with the mortality from this disease; and he admitted that there were sanitary defects in the institution with which he was connnected, the building being only a temporary one, not constructed for the purpose of a hospital; but these sanitary defects, like the mortality itself, were no greater than in any institution of the city. He considered it not a matter to elicit wonder or comment, that the children he reported should have succumbed to the disease when it is remembered that they were suffering from such serious maladies as cerebro-spinal meningitis and tuberculosis.

DR. JOSEPH RANSOHOFF narrated a case in which he was called upon to perform a tracheotomy for the relief of severe dyspnœa, which appeared in consequence of diphtheria as a complication of measles. He was not conversant with the previous history of the case, but was of the opinion that the child, about two years of age, had just passed through an attack of measles of moderate severity, and without any very alarming symp-

toms until the dyspnœa supervened, about sixteen or seventeen days after the inception of the disease. When he first looked at the child, it was suffering from the most marked dyspnœa, with all the evidences of laryngeal stenosis, namely, cyanosis, sinking in of the suprasternal notch, etc. The child was comatose. The pulse did not, however, indicate approaching dissolution, for it had a fair volume, and ranged from about 160 to 180 per minute, so that he did not think that the coma was due entirely to the dyspnœa. In addition to the dyspnœa and accompanying aphonia, the child presented all the appearances of a tubercular meningitis. It lay with its head away back, burrowed in the pillow; its temperature was 103½°; the pupils were much dilated, and reacting rather irregularly to light. The tracheotomy was, however, made in the hope that the immediate symptoms of dyspnœa being relieved, the other alarming manifestations might subside. Not a particle of membrane, or other foreign matter, was found below the incision, except a little mucus, and that was untinged with blood. The child breathed better at once, and the sinking in of the epigastrium was relieved. It did not, however, regain consciousness, and died in about twenty-four or twenty-six hours after the operation. No good had been accomplished except to relieve this dyspnœa.

He stated that he had been called to see a case only a few days since in which there was a diphtheritic membrane in the throat, but in which the symptoms were not severe enough to warrant the resort to tracheotomy. In connection with the case in which he had performed the operation, he desired to ask the Academy whether a tubercular deposit in the lungs could be alone sufficient to cause a dyspnœa resembling that accompanying a diphtheritic deposit in the larynx.

Dr. R. Stewart reported a number of cases that had occurred in his practice. Catarrhal pneumonia had occurred in about forty per cent. of the cases that he had treated during the present epidemic; in two he had observed enlargement of the bronchial glands; in one case he thought that he was about to have diphtheria, on account of the exacerbation of temperature, reaching 104°, with enlargement of the cervical lymphatic glands; a complaint of pain in the throat, with the peculiar dark-redness of the mucous membrane; and a whitish patch, running across from one tonsil to the pharynx, that looked like the commencement of a membrane. But under the local application of the oil of eucalyptus in alcohol, and large doses of the tincture of the chloride of iron internally, the alarming symptoms subsided. He did not think that he had aborted a case of diphtheria, but suggested the possibility that a great number of cases of diphtheria which are supposed to complicate measles are in reality simply such cases as the one he had reported.

In one case, the speaker had observed all the premonitory symptoms, without exception; but when the time came for the eruption to appear, he could find only a few small spots on the face. The day following, he found on the left cheek about a dozen petechiæ. The case proved a mild one.

Two cases were in adults; in one of them the premonitory symptoms were complete, but no eruption appeared. In the other, the disease went through its various stages, and was accompanied by a very severe bronchitis. The speaker lost one case from catarrhal pneumonia. This occurred in a child one year old, belonging to a phthisical family. The hygienic surroundings were bad, and the pneumonia proved fatal within forty-eight hours after he first saw the case. The child had had measles, but the speaker did not see the case during the presence of the eruption, but only when the pneumonia was well pronounced, the temperature at time of his first visit being 107° in rectum.

In conclusion, he reported two cases which resembled the one reported by Dr. Ransohoff. Both of them had symptoms of laryngismus stridulus, concomitant with those of catarrhal pneumonia. There was hoarse, barking cough, and aphonia, with marked cyanosis. In one case, just as the child was dying, a tracheotomy was performed, with the idea of possibly affording some relief. The post-mortem examination revealed well-marked catarrhal pneumonia, but no membrane; nor, indeed, any redness of the tracheal mucous membrane.

In the other case, no tracheal redness was found post-mortem, but catarrhal pneumonia was well marked.

Dr. Whittaker said that it was strange to hear of two cases of measles in which tracheotomy had been performed and nothing found in the trachea. He fully agreed with the previous speaker as to the rarity of diphtheria as a complication of measles; he had never seen it. Common as it is in scarlatina, so rare it is in measles. Laryngismus stridulus is, however, much more common. Sometimes we can discover the cause of the complication; sometimes we can find a punctate or diffuse eruption somewhere on the laryngeal folds. If it should attack the inter-arytenoid fold, it might easily cause laryngismus stridulus. The laryngoscope would reveal these spots. Although these cases are thus not pure neuroses, all that he had ever seen had been relieved by the administration of emetics.

In regard to the appearance of Bright's disease in the course of measles, he thought it going too far to consider every case of albuminuria a case of that affection, since a transitory albuminuria is likely to occur in every case of fever. The nephritis of scarlet fever is really a post-scarlatinal process. He would also look with great suspicion on a case of measles occurring in the course of a cerebro-spinal meningitis; and he would prefer to consider it a case of measles primarily, with the meningitis occurring as a complication of that disease. He would not base the diagnosis merely upon post-mortem appearances, since both are acute infectious diseases with the same localization, and would hence have many lesions in common. He thought it better to rest it upon the symptoms that were observed. Fatal cases in which the eruption does not appear, he said, have been observed in all the acute infectious diseases, and grave or malignant cases are prone to show an early meningitis.

In reply to the question, "What would you do in a case of marked dyspnœa in which emetics did no good?" the speaker said that it would be just as possible for a child to die from laryngismus stridulus as from asthma. He did not think, in other words, that the symptoms could last long enough to produce death. They were alarming, but they alarmed the parents rather than the physician. The dyspnœa in these cases depended upon catarrhal pneumonia, and not upon laryngitis. The

laryngeal spasm in these cases is largely neurotic. He might administer an anæsthetic.

Dr. Ransohoff remarked that the theory of carbonic acid intoxication was a very nice one, but that he had seen two or three cases of asthma die during or immediately after the paroxysm. In the case he had reported he was positive that there was no catarrhal pneumonia; there had been no history of a catarrhal pneumonia, and the symptoms when he saw the patient were not those of that disease. There was evidently some obstruction in the larynx, and it was on this account that he had performed the operation. Laryngismus stridulus had been thought of, but it did not appear like a case of that nature; for if coma reduces muscular spasm, why was the spasm not relieved in this case? The child had been comatose for two days, but there was no sign of relaxation. The tracheotomy relieved the dyspnœa, and he was satisfied that it did not shorten life. The operation of tracheotomy he considered entirely devoid of danger, the deaths occurring only from complications. The fact that there was no membrane below the opening, was not evidence that there was none above that point, and, in fact, a slight vestige of diphtheritic deposit was apparent in the throat.

Dr. Forchheimer remarked that the term laryngismus stridulus meant a great many things. He had invariably applied it to the purely nervous affection, carefully excluding all cases of so-called false croup in which there is a marked catarrhal condition of the mucous membrane. In cases of the latter disease, he would not hesitate to open the larynx. It is a disease of comparatively no importance, but cases do die from it and from the dyspnœa that it produces. In regard to the nervous form, he thought that tracheotomy was sometimes imperative in it also, in order to remove the dyspnœa and the irritation of the lungs which it produces.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, February 5, 1885.

The President, B. F. Baer, M.D., in the Chair.

OVARIAN CYSTS.

Dr. Baer exhibited two ovarian cysts. Mrs. B., widow, entered his private hospital December 18, 1884. She commenced eight months before to suffer from frequent calls for micturition with severe scalding pains, symptoms apparently of cystitis and urethritis. The uterus and ovaries were in good position and seemed normal, but two weeks later there was a burning pain in both ovarian regions with a perceptible bulging, largest on the right side. The menses had ceased, and the doctor in attendance suspected pregnancy, but exposure was denied at that time. The abdomen enlarged rapidly, and the patient finally acknowlenged the possibility of pregnancy, and thought she felt movements of the fœtus. At seven months uterine hemorrhages commenced, and continued every day; the mammæ were atrophied; there were no signs of the presence of a fœtus; there was some fluctuation; the sound was passed and the uterus was found empty and not enlarged; the face was wasted and had an anxious expression, and the pulse was quick. A diagnosis of ovarian cyst was now made. A deep diagonal sulcus could be made out in the abdominal tumor, the largest portion being on the right side. The surface of the tumor was smooth and without nodules. The cervix was soft, patulous, high up, and drawn to the left. When the tumor was moved the uterus moved with it, as shown by the handle of the sound. Immediate operation was advised and performed. Incision three and a quarter inches, two large tumors were revealed, both were tapped; the left which was free from adhesion was withdrawn without difficulty, its pedicle transfixed, ligated, and dropped. The larger tumor, although free from abdominal adhesions, could not be drawn out, and it was found to be very tightly adherent to the uterus, which seemed to be one mass with it. As the fluid drawn from this tumor was clear, it is not improbable that it was a cyst of the broad ligament. It became necessary to enucleate the cyst, and a long gaping wound was left in the broad ligament; this was transfixed and tied as a pedicle, but after the final division had been made the ligature slipped and the hemorrhage was immense; ten hæmostatic forceps were applied temporarily, and the bleeding points were firmly secured. The wound of the broad ligament was closed by ten interrupted sutures. The operation lasted two and a half hours; the patient collapsed, and he feared she would die on the table; but she reacted and recovery was uninterrupted, the patient sat up in two weeks. An incident which occurred on the fourth day shows the necessity of the proximity of a physician or thoughtful nurse. A scream from the patient, an announcement of a sudden pain on the right side, and the patient said something seemed pulling inside of her. Dr. Baer was near and was called; he feared internal hemorrhage, but at once inquired how long it had been since she had passed water—four hours—the catheter was immediately used and complete relief was secured. After this the catheter was not required until the tenth day, but from the tenth to the twentieth day there was entire inability to pass water except by assistance of the catheter. She went home on the twenty-third day.

The points of special interest in this case are:

1st. The patient being entirely well, symptoms of gonorrhœa presented themselves, and were followed by

2d, amenorrhœa for seven months, followed by

3d, daily hemorrhages for one and a half months.

4th. Ovaritis and large tumors forming in eight and a half months from the initial symptoms.

Dr. Beates mentioned the case of a young lady who was obliged to separate from her husband one month after marriage in consequence of domestic trouble; her menses continued regular, but her abdomen enlarged as rapidly as if she were pregnant; her health failed, and at the expiration of nine months an ovarian tumor was removed; recovery was complete and rapid.

In another case he found numerous omental and enteric adhesions which were easily separated, but pelvic adhesions required enucleation of the cyst, which left a large V-shaped wound in the broad ligament as described by Dr. Baer. Hemorrhage was very free; in trying to dissect off the tumor from the fundus of the uterus, that organ was badly wounded; the cavity was opened, and required to be closed by sutures. Great tympany followed this operation, and breathing became almost impossible; the patient recovered.

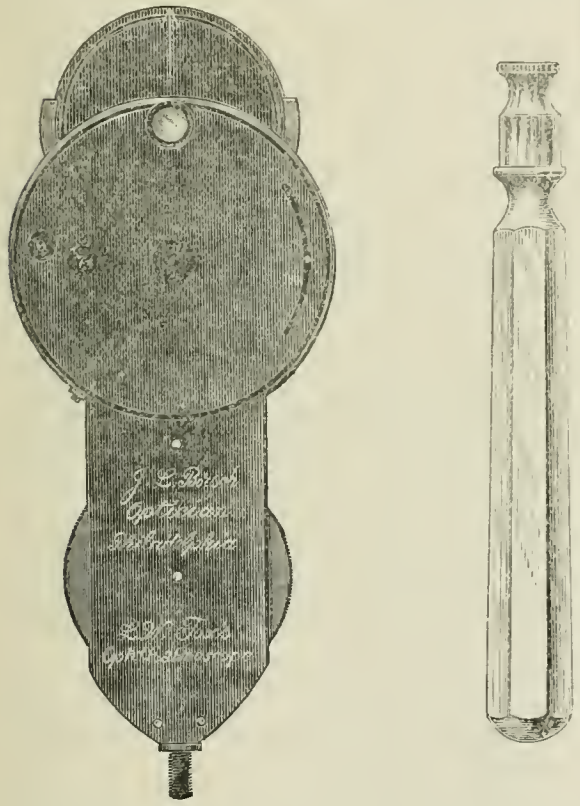
NEW INVENTIONS.

AN IMPROVED REFRACTION OPHTHALMOSCOPE.

By L. WEBSTER FOX, M.D.,

OPHTHALMIC SURGEON, GERMANTOWN HOSPITAL; LATE CLINICAL ASSISTANT, MOORFIELD'S EYE HOSPITAL, LONDON, ETC.

This instrument is a modification of an ophthalmoscope which we designed in 1880 while at Moorfield's Eye Hospital. The size and weight having been reduced about one-third, makes it now an instrument of beautiful design and complete workmanship. The illustration below represents its full size. The main features of this instrument are the toothed-wheel mechanism, the short focal length of mirror for direct examination, and the large combination of lenses. It has two mirrors, with focal lengths of eight centimetres and twenty centimetres respectively. The mirrors are



set obliquely, and can be rotated to any angle, an advantage when the instrument is used in a sick-room or the wards of a hospital. By direct examination, the rays of light from the short focal mirror are crossed in the lens of the patient's eye, consequently, we do not have an inverted image of the lamp on the retina, but an evenly diffused circle of illumination. An arrow on the back of the mirror indicates the angle at which it should be set, which we have found to be about twenty degrees above the horizontal; this throws the handle away from the patient's face to admit a free movement of the index wheel, an advantage which ordinary ophthalmoscopes do not possess. The arrow points towards the lamp when the mirror is set properly.

In high degrees of myopia (above twenty dioptrics), owing to the fact that the area illuminated becomes greater, due to the length of the eyeball, the illumination becomes fainter; sufficient light is retained, however, to see the most minute pathological change; this may be wholly overcome by shortening the distance between lamp and mirror, and if greater intensity of light is desired, the twenty centimetre mirror can be substituted. We would call especial attention to the great advantage of the short focal mirror in the examination of morbid changes in the retina and choroid, also to the examination of lens and cornea. The long focal mirror is useful for indirect examination and retinoscopy.

The disk, which has a diameter of forty-two millimetres, has twenty-two apertures, admitting ten convex and eleven concave lenses, added to this is a crescentic slide with five apertures containing four lenses. By combination, the following range of glasses may be obtained: +0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5, 5.5, 6, 6.5, 7, 7.5, 8, 8.5, 9, 9.5, 10, 10.5, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22; and —0.5, 1, 1.5, 2, 2.5, 3, 3.5, 4, 4.5, 5, 5.5, 6, 6.5, 7, 7.5, 8, 8.5, 9, 9.5, 10, 10.5, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 35.

The lenses are brought forward by the toothed wheel system: one wheel is set on the disk, a second between this, and the third (or finger-wheel) lowest of all. They are all enclosed, only the milled edge of the third projecting far enough to allow its being rotated by the index-finger. Each lens is centred accurately with the hole in the mirror by a spring action, having its point of pressure on the peripheral edge of the primary disk. The disks and cap are held in place by screws; by removing them, all can be taken apart when necessary. The instrument is well balanced by a good-sized ivory handle and packed in a small case. Each ophthalmoscope is accompanied by a large lens one and three-quarters inches in diameter, having a focal distance of two inches.

Messrs. Ferrier & Hawkins, of London, and J. L. Borsch, 1324 Walnut Street, Philadelphia, are the makers.

NEWS ITEMS.

Prevalence of Measles in New York City.—A report concerning the recent increase of measles in New York City was presented to the Board of Health, on Tuesday, by Chief Inspector James B. Taylor. The record for four months is as follows:

	Nov.	Dec.	Jan.	Feb	Total.
Cases	385	484	743	540	2152
Deaths	60	75	157	111	403

The record of the disease is made from the returns of physicians, and the cases are not always returned, unless the patients die. In one public institution containing 200 infants, there have been 157 cases of measles and 65 deaths in four months. Dr. Taylor's report contains the following:

Such a rate of mortality is almost unaccountable, and if the same rate prevailed elsewhere, it would prove

measles to be the most virulent of all contagious diseases. It has taken the lead over all the past two months. Even that greatly dreaded disease, diphtheria, has been left behind, as there have been from the latter 534 cases and 234 deaths during the same period, compared with 1283 cases and 263 deaths from measles. It is well known that measles is usually more fatal during the winter months, owing to the greater danger from the complications which are so certain to accompany it, such as bronchitis, pneumonia, and croup, and which only the greatest care can guard against. I recommend that the attention of physicians as well as citizens be directed to this excessive mortality, and that great care be exercised as regards isolating and careful nursing. At the present time, the disease seems to be extremely contagious. By a more careful isolation of the sick from the well, there is no doubt that its progress could at once be checked very materially.

University of Pennsylvania.—At the meeting of the Trustees of the University, held on Tuesday, Dr. Harrison Allen presented his resignation of the Chair of Physiology in the Medical Faculty.

At the same meeting, Dr. W. L. Zuill was elected to fill the newly created chair of Surgical Pathology, connected with the Veterinary Department.

Plans were approved for the erection of a building, to comprise stables and a hospital for the Veterinary Department. The plans, as at present drawn up, provide for a building 210 by 36 feet, with a ten-foot covered piazza. The masonry is of stone and red brick, and the estimated cost in the neighborhood of $20,000. It includes a library, armory, pharmacy, stalls, a large horse-foot bath, and a round stall designed for insane horses. The proposed floors are to be of cement, and great attention is to be given, it is stated, to drainage.

Rush Medical College, Chicago.—The Annual Commencement of this institution was held on February 17th, and the degree of M.D. was conferred on 151 graduates. The whole number of students attending during the winter term was 401.

The Hospital Medical College of Evansville, Ind.—The Third Annual Commencement of the Hospital Medical College of Evansville was held February 27, 1885. The degree of M.D. was conferred on six candidates.

The New York Polyclinic has arranged to open a pathological and histological laboratory under the direction of Dr. F. S. Billings, whose connection with the laboratory of both Koch and Virchow for several years should adapt him admirably for the position. It is proposed to have two courses—one in pathological histology and morbid anatomy and a higher scientific course including bacillus culture.

Ex-Surgeon-General Wales.—Charges of inefficiency in performance, and neglect, of duty have been preferred by the Secretary of the Navy against ex-Surgeon-General Wales, of the Navy, and a court-martial has been detailed to try them. These charges have grown out of the recent trials for frauds in the Bureau of Medicine and Surgery.

State Board of Health of West Virginia.—Dr. James E. Reeves, of Wheeling, has just resigned the Secretaryship of the West Virginia State Board of Health, and his many friends will greatly regret to learn that the state of his health has compelled him to sever himself from this office with which he has been connected since the inception of the Board, and in which he has done such excellent work. His resignation is a loss to the State, and the Governor, in accepting it, recognizes this. As regards his earnest labors for the promotion of the public health and the elevation of the standard of the medical profession in the State, the Governor, in a letter, accepting his resignation, says: "You have devoted a large share of your valuable time, aided by a ripe experience, to medical and sanitary science. Your labors in conjunction with the other members of the Board have raised the standard of the profession to a higher plane than before attained by it, and through the operation of our health laws, placed the State on advanced ground in the development of sanitary science."

A Russian Translation of Dr. Weir Mitchell's admirable brochure on "Fat and Blood" has just been published in St. Petersburg.

The German Imperial Health Office.—Dr. Köhler has just been appointed Director of the Imperial Health Office at Berlin. According to the German journals, his appointment has elicited general satisfaction, and it is anticipated that under his direction the continued effective working of the office, with which the reputation of Dr. Koch is so intimately connected, will be continued.

Dr. Koch.—It is announced that a Chair of Hygiene is to be established in the Berlin Medical Faculty, to which Dr. R. Koch will be appointed. It is also intended by the Government to establish full Professorships of Hygiene in the other Prussian universities, the only one that at present has such a professorship being the University of Göttingen.

Prof. Lucae died recently at Frankfort-on-the-Main. His anatomical and anthropological works achieved much for the advancement of science, and rendered his name widely known.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING FEBRUARY 28, 1885.

Purviance, George, *Surgeon*.—Granted leave of absence for one week, Feb. 24, 1885.

Kalloch, P. C., *Assistan Surgeon*.—When relieved, to proceed to Pittsburg, Pa., and assume charge, Feb. 27. 1885.

White, J. H., *Assistant Surgeon*.—To proceed to Savannah, Ga., and assume charge, Feb. 24, 1885.

The Medical News *will be pleased to receive early intelligence of local events of general medical interest, or of matters which it is desirable to bring to the notice of the profession.*

Local papers containing reports or news items should be marked.

Letters, whether written for publication or private information, must be authenticated by the names and addresses of their writers—of course not necessarily for publication.

ORIGINAL LECTURES.

CHRONIC INTERSTITIAL NEPHRITIS (CONTRACTING KIDNEY).

A Clinical Lecture, delivered February 12, 1885.

BY ROBERT T. EDES, M.D.,

JACKSON PROFESSOR OF CLINICAL MEDICINE IN HARVARD UNIVERSITY.

GENTLEMEN: The patient before us entered the hospital a few days ago. He was here also last May, in much the same condition, except that he has grown manifestly thinner and weaker, and has been a little delirious. When he first entered he had had some headache, vertigo, and dyspnœa, and complained of dimness of vision, which he attributed to cataract, having already had one removed. It was found, however, that the defect in sight arose from albuminuric retinitis. His urine was rather abundant, of low specific gravity, contained a small amount of albumen, and some hyaline and granular casts. The area of the heart's dulness was not absolutely beyond the normal limits, but was quite up to the extreme, and there was a systolic souffle to be heard at the base. There was no dropsy. The sphygmograph showed a tracing with a moderately strong up-stroke, a little peak at the summit, and then a gradually rounded top and uniform descent, hardly interrupted by any dicrotic wave; indicating that the blood passed but slowly from the artery in either direction; not regurgitating into the ventricle, nor allowed to escape with undue rapidity through the relaxed arterioles.

We now find that his vision has decreased, and we can distinguish two souffles at the base, one systolic and one diastolic, the latter being much the weaker. A faint one is also to be heard at the apex, probably distinct from that at the base. The area of the heart's dulness is somewhat increased, but the impulse is not violent. Our sphygmographic tracing is, as you see, almost identical with that of last May (nine months ago), and is highly interesting as showing a constant condition of the circulation, and also as proving the accuracy of the instrument in recording such conditions; which one often feels inclined to doubt in watching the great changes in the result made by various circumstances, but especially by the amount of pressure employed in adjusting the pad upon the artery. As I have told you before, the important thing for us to know about the action of the heart is how it is doing its work, and not how much noise it makes about it; and it is very evident from this tracing that the diastolic murmur cannot signify any amount of regurgitation sufficient to affect the amount of blood in the arterial system. As to the systolic murmur at the apex, it is certainly common enough in such cases to meet with it when there is no reason to suspect valvular lesions of consequence.

The condition of the patient's urine is about the same as before. We have evidently here a typical case of that form of Bright's disease dependent chiefly, so far as the kidney is concerned, upon an interstitial inflammation, or an increase of the connective tissue. We are in the habit of speaking of two distinct forms almost as if they were two anatomically distinct diseases, as sometimes they are; but it can hardly be supposed that the deposit of new tissue among the tubes of the kidney, with its subsequent cicatricial contraction, can go on for years without affecting the secreting structure of which it forms the support; and, on the other hand, a chronic inflammation of the secreting surface, such as goes on in parenchymatous nephritis, is exceedingly likely to set up more or less hyperæmia and hypertrophy of the underlying tissues. Hence, although we have at one end of the series an exceedingly well-marked clinical group in which the initial lesion of the kidneys is in the connective tissue, and at the other, cases in which for a time the parenchymatous elements may be alone affected, yet we find a great many various grades of intermixture between the two.

In the form which we have at present before us, however, we have more to consider than the renal lesion alone. The condition of the heart and circulation is more than an accidental complication. It is a part and, according to some who have speculated upon its pathology, the most important and essential part of the disease; so much so that Dr. Mahomed, who gave a great deal of attention to the early stages of this affection, speaks of cases of Bright's disease which die without nephritis. This appears to me a misuse of language, since Bright's disease certainly ought to mean the disease that Dr. Bright described; and, although he had noticed and endeavored to account for the cardiac hypertrophy so often met with, yet he was writing, not about lesions of the heart, but those of the kidney. Setting aside, however, the question of nomenclature, it is certainly a great merit in Dr. Mahomed, whose early death we cannot consider otherwise than a great loss to medical science, to have called attention to the fact toward which other observers have been working, that so-called chronic Bright's disease of this form is really a general and not simply a local one.

While it is impossible, in the light of numerous observations which show the same condition under widely different circumstances, to accept the pulse or tracings of high arterial tension as at all conclusive of the imminency of Bright's disease, yet it is perhaps prudent to consider such a condition as being, in the first place when accompanied by grave symptoms, one more point in the diagnosis; and secondly, what is perhaps of more importance, to look upon a continued high tension, when occurring with only slighter disturbances, as a distinctly morbid condition, increasing usually with advancing years and rigid arteries, and hence of more significance when found in young or middle-aged persons.

Chronic interstitial nephritis is undoubtedly one of the dangers ahead, and it is highly probable that treat-

ment directed toward the condition known as lithæmia or incomplete nitrogenous metamorphosis, and embracing diminished nitrogenous diet, diminished acids and acid-forming material, attention to the action of the liver and bowels and sufficient exercise, may be the means of avoiding this as well as other dangers. Fortunately, the rules of hygiene, as well as the resources of medicine, do not always need for their practical application an exact knowledge of the remoter dangers. Such treatment harms few or none among the patients to whom it is likely to be applied, and is as useful in the prophylaxis of many other diseases as of Bright's. That mental tranquillity, so easy to advise and so hard to get, is no insignificant adjunct to such treatment. Dr. Allbutt has shown the importance of distress and worry as factors in the etiology of the contracting kidney, and it has certainly seemed to me that the most typical cases were to be found among middle-aged, active, anxious business men.

The theories between the changes in the kidneys, the heart, and the circulation are too numerous, too complicated, and, I may be allowed to add, not well enough established to be discussed here. The later ones, however, tend less than those of earlier date to attribute the cardiac hypertrophy simply to interference with the renal circulation. There are, however, experiments (those of Grawitz and Israel) and cases which go to show that destruction or injury to a considerable portion of the secreting structure of the kidneys, notwithstanding a very free formation of urine, may give rise to hypertrophy of the heart.

Such a case was the following: A boy, aged 5, had always passed urine copiously and frequently. Notwithstanding its involuntary passage, he could always pass more when called upon, The urine presented no peculiarities, except a very low specific gravity, a small amount of albumen with a deposit of a few pus cells, and no casts. He died two years later with headache and convulsions. The bladder was found very large, the urethra unobstructed, and the ureters dilated completely down to their entrance into the bladder and up to the kidneys, the pelves of which were dilated and the secreting substance much atrophied, that on the right side being reduced to a few very thin patches and a nodule at one end. The arterial system appeared healthy, but the left ventricle was large, thick, and firm. The sequence of events seemed here to have been paralysis of the bladder, dilatation of the ureters, atrophy of the kidneys, hypertrophy of the heart.

In the case before us, we are apparently dealing with one in which the cardiac and renal lesions are progressing side by side. The urine shows us the usual somewhat abundant quantity, abundant, that is, in proportion to the amount of fluid taken, a small amount of albumen, and a few casts. The general symptoms are as yet rather those of gradual failure than of local lesions or the effect of excrementitial accumulation. There is no dropsy, and, beyond some moderate delirium, no cerebral symptoms, neither paralysis nor convulsions. He has not even that intense "nervousness," or restlessness, or vague distress sometimes seen. Gastric disturbance is not extreme, although he does not eat a great deal, and he has had some, but not persistent, vomiting.

How far can we interfere in such a case to advantage? We could treat some of his symptoms; we can regulate his diet, give him partially digested food; administer bismuth or lime-water or digestives for vomiting; give morphia or caffeine for severe headache, give morphia or the hot-air bath or jaborandi (better the bath) for headache or convulsions; cathartics for dropsy, or tap him for an effusion sufficient to cause dyspnœa; but, unfortunately, he has none of these symptoms, and our question refers to his evident steady but tolerably comfortable progress toward a fatal termination.

I know no good reason to suppose that any drug has the power to remove the excess of interstitial tissue from the kidney, nor if it could do so that the secreting structure could be otherwise than irreparably damaged. Iodide of potassium has failed. Dr. Bright knew that mercury ought not to be given, and there is little to be hoped for in the other members of the same chemical group. The usual history of such cases goes to show that progress, though slow, is certainly, when advanced as far as this, steadily onward.

There is a class of drugs which have the power rapidly to reduce the tension of the arteries. These are the nitrites of amyl, of sodium, of potassium, of ethyl (spiritus ætheris nitrosi), and nitroglycerine. Of these, the latter has been used in some cases of Bright's with good results, of which one is claimed to be an increase in the quantity of urine.

In cases of the kind now under consideration, the urine is usually during the whole, or nearly the whole, progress of the disease sufficiently abundant, and the instances reported by Mr. Robson of the beneficial action of this drug in chronic Bright's disease do not seem to me to have been interstitial nephritis, but rather parenchymatous or mixed. Asthmatic symptoms, such as may often be present, and were so in some of his cases, are likely to be greatly relieved thereby. As to acute cases, the prognosis is so favorable under treatment directed toward sufficient elimination by the skin and to relief of irritation in the kidneys, that we can hardly consider successful results in a few cases as proving a great deal as to the value of a more specific treatment. In one case in which the tension was persistently high, I tried the effect of nitroglycerine on several occasions, carefully observing the pulse by the sphygmograph both before and at various intervals after the administration of doses as large as five minims of the usual solution (1 to 100) without perceptible effect. This was only case, however, and I have not repeated the experiment. I do not find that this remedy has as yet conquered a place for itself as the accepted or even a specially important one in renal disease of this kind.

It seems to me highly improbable that in the fully developed disease these agents, although useful in the relief of some symptoms, can materially modify its course. In the earlier stages, the dietetic and hygienic rules already spoken of, with attention to the bowels and skin, are of more importance and greater efficiency.

It is interesting to note that the high tension prevailing through the course of the disease may be temporarily modified by fever without producing any permanent change for the better.

A middle-aged man, who presented during his months of stay in the hospital uniformly the signs of high ten-

sion as well as the urinary symptoms of contracting kidney, had, on several occasions, acute attacks of a gouty character, during which the tension fell and the pulse presented, as shown by the sphygmograph, the usual characteristics of fever; a strong primary rise succeeded by a rapid fall and strongly marked dicrotism. This remark does not apply to the fever accompanying acute nephritis. In this affection, the tension falls with the improvement in the other symptoms.

IV.

DRY HEAT.

BY GEORGE H. ROHE, M.D.,

PROFESSOR OF HYGIENE IN THE COLLEGE OF PHYSICIANS AND SURGEONS, BALTIMORE.

THE first accurate observations on the disinfecting power of dry heat were made by Henry, of Manchester, in 1831. (Quoted in E. Vallin: *Traite des Désinfectants*, Paris, 1882, p. 226.) Henry exposed (fresh?) vaccine virus to temperatures varying from 50° to 82° Cent. (122°–180° Fahr.) for two, three, and four hours, and secured complete disinfection, none of the specimens of vaccine thus exposed producing vaccinia when subsequently inoculated. Exposure for three hours to a temperature of 49° C. (120° F.) failed to disinfect. No control experiments with non-disinfected virus were made by this observer.

E. B. Baxter (*Report Medical Officer of Privy Council*, etc., N. S., No. vi. p. 216) exposed dry vaccine to a temperature of from 90°–95° C. (194°–203° F.), for thirty minutes. Disinfection was complete. Vaccination with disinfected virus was unsuccessful. Control inoculations with non-disinfected virus were successful.

Carstens and Coert reported to the International Hygienic Congress of 1879 (quoted by Vallin, in the above-mentioned work) the following conclusions:

Fresh animal vaccine heated to 64.5° C. (148° F.) for thirty minutes loses its virulence. Fresh animal vaccine heated to 52° C. (125° F.) for thirty minutes does not lose its virulence. The maximum degree of heat to which fresh vaccine can be exposed without losing its infectivity probably varies between 52° and 54° C. (125°–129° F).

Davaine, in 1873, destroyed the virulence of fresh anthrax blood[1] by exposing it to temperatures of 55°C. (131° F.) for five minutes, 50° C. (122° F.) for ten minutes, and 48° C. (118° F.) for fifteen minutes.

Werner, in 1879, exposed putrefactive bacteria on pledgets of cotton and then enveloped in dry cotton to a temperature of 125° C. (257° F.) for one hour, and secured complete disinfection.

[1] Containing bacilli, but no spores.

Merwich (*Deutsche Med. Wochenschr.*, 1880, p. 498) exposed putrid material (containing bacteria of putrefaction) to a temperature of from 125°–150° C. (257°–302° F.) for five minutes with like success.

Schill and Fischer (*Mitth. a. d. Kais. Gesundheitsamte*, Bd II. S. 134) found that exposure for one hour to a temperature of from 100°–130° C. (212°–266° F.) destroyed the virulence of tuberculous sputum, as tested by the inoculation of rabbits and other animals.

Koch and Wolffhügel (*Mitt. a. d. Kais. Gesundheitsamte*, Bd. I.) experimented with a large number of pathogenic and non-pathogenic organisms. A temperature varying from 78°–123° C. (172°–253° F.) maintained for one hour and a half (over 212° F. for an hour) sufficed to kill micrococcus prodigiosus and the bacilli of septicæmia of mice and rabbits, but failed to destroy the spores of bacillus anthracis and of various non-pathogenic bacteria and fungi.

Micrococci and bacilli containing no spores, and spores of mould fungi, were completely killed by one and a half hour's exposure to a temperature of from 120°–128° C. (248°–262° F.); but spores of B. subtilis, B. anthracis, and of a bacillus growing upon potato, resisted a second heating to the same temperature for a similar length of time.

These authors further experimented upon a number of organisms disposed in various ways in the disinfecting chamber, so as to approach in a measure the conditions of practical disinfection. Some of the articles were placed in coat pockets, others rolled up in balls of cotton, oakum, blankets, or soiled clothing, making packages of different thickness and density. The organisms consisted of micrococcus prodigiosus, micrococcus of blue pus, bacillus anthracis, and bacilli found in garden soil. With each package was placed a registering thermometer to indicate the highest temperature reached during the experiment. The temperature in the chamber varied from 133° to 156° C. (271°–313° F.), and the exposure was continued for three hours and ten minutes. The temperatures in the different packages varied from 74.5° C. (167° F.) to 121.5° C. (251° F.). In none of the packages were the spore-bearing organisms destroyed. In a small iron vessel hanging free in the chamber and containing specimens of the same organisms, a temperature of 139.5° C. (283° F.) was indicated by the thermometer. Here complete disinfection had taken place.

Another series of observations with the temperature in the chamber varying from 131°–140° C. (267°–284° F.), and exposure continuing for three hours, resulted as follows: The organisms (micrococcus prodigiosus, spores of bacillus anthracis, and of bacilli of garden soil) and registering thermometers were enclosed in packages of clothing, bedding, and rolls of blankets. Complete destruction of the spore-bearing organisms did not follow unless the temperature of 139°C. (282° F.) had been reached. In one large package consisting of nineteen blankets, thoroughly dried and rolled up, the heat did not penetrate to the interior in a sufficiently high degree to destroy the vitality of micrococcus prodigiosus even.

These experiments were still further varied, but the results obtained did not differ materially from those

already given. They all showed the great difficulty of penetration of thick packages of fabrics of various kinds by a sufficiently high temperature to produce disinfection.

A large number of fabrics (linen, silk, cotton, wool, feathers, paper, and leather) were exposed for five hours to a temperature of from 150°–160° C. (302°–320° F.), with the result of producing such changes in color and texture of most of them so as to render them useless.

In a similar series of experiments, Ransom (*Practitioner*, 1878, p. 67) found that exposure to a temperature of from 240°–250° F. would be borne by clothing materials without injury. Vallin (*op. cit.*) states that cotton and wool fabrics do not change color at a lower temperature than 125° C. (253° F.), which corresponds closely with the observations of Ransom.

Koch and Wolffhügel (*op. cit.*, p. 321) submit the following conclusions, which seem to the writer to be fully justified by the results of their own and other observations here collected:

1. A temperature of 100° C. (212° F., dry heat), maintained for one hour and a half, will destroy bacteria which do not contain spores.
2. Spores of mould-fungi require for their destruction in hot air, a temperature of from 110°–115° C. (230°–239° F.) maintained for one hour and a half.
3. Bacillus spores require for their destruction in hot air, a temperature of 140° C. (284° F.) maintained for three hours.
4. In dry air the heat penetrates objects so slowly that small packages, such as a pillow or small bundle of clothing, are not disinfected after an exposure of from three to four hours, to a temperature of 140° C. (284° F.)
5. Exposure to a temperature of 140° C. (284° F.) in dry air for a period of three hours injures most objects requiring disinfection (clothing, bedding, etc.) to a greater or less degree.

V.

MOIST HEAT.

BY GEORGE M. STERNBERG, M.D.,
SURGEON, U. S. A.

WHENEVER infectious material can be consumed by fire, there can be no question as to the efficiency of this mode of disposing of it. But from the experimental data given in the preceding paper, it will be seen that the destruction of desiccated spores by dry heat requires a temperature which injures textile fabrics.

It is quite different with moist heat, and in steam, at a temperature of from 105° to 110° C. (221° to 230° F.), we have an agent which quickly destroys all living organisms, including the most refractory spores.

In the absence of spores, all known microörganisms are quickly destroyed when immersed in boiling water. Indeed, a temperature much below the boiling-point destroys micrococci and bacilli in active growth. Thus I have fixed the thermal death-point of the micrococcus of septicæmia in the rabbit, and of the micrococcus of pus (from an acute abscess) at 140° F. (60° C.), the time of exposure being ten minutes. This temperature is also fatal to the micrococcus of swine plague. The micrococcus of fowl-cholera is destroyed by exposure for fifteen minutes to a temperature of 132° F. (Salmon). Nine or ten minutes' exposure to a temperature of 54° C. (129.2° F.) is sufficient to destroy the vitality of anthrax bacilli in blood (Chauveau). Davaine has shown that, owing to the low thermal death-point of this bacillus, it may be destroyed in an inoculation wound by the application of heated metal to the surface —hammer of Mayor. May it not be that the *rationale* of the effect of poultices applied "as hot as can be borne" to furuncles, acute abscesses, etc., is to be explained in the same way? Or, at least, if a temperature sufficient to destroy the vitality of micrococci which have invaded the tissues cannot be borne, is it not probable that their multiplication may be prevented by the continued application of a bearable temperature?

The resisting power of spores is very much greater, and it is well known that the spores of *B. subtilis* and of other species of the genus *Bacillus* withstand a boiling temperature for a considerable time. My culture-fluids have frequently "broken down," on account of the presence of the spores of *B. subtilis*, after two hours' boiling, and, to insure sterilization, I am in the habit of resorting to a second boiling, after an interval of twelve hours, or of sterilizing in a bath containing some salt by which a higher temperature than that of boiling water can be secured.

A temperature of five degrees Centigrade (9° F.) above the boiling-point quickly destroys the most refractory spores. I have recently made numerous experiments upon the spores of *B. anthracis* and *B. subtilis*, which show that the former has less resisting power than the latter, but that both are destroyed by a temperature of 105° C. maintained for ten minutes. The same temperature failed to destroy the developing power of the spores of *B. subtilis* in five minutes, while two minutes' exposure destroyed the vitality of anthrax spores.

These results are in accord with those of Koch, Gaffky, and Loeffler,[1] who found, as the result of numerous experiments, that when a temperature of 105° and upwards was maintained for ten minutes, all spores were destroyed, as shown by their failure to develop in culture-solutions. Where a temperature of 110° C. was reached, the experiment could be stopped, as no spores were capable of germinating after exposure to this temperature. Exposure to a temperature of 100° to 105° C. for twenty or thirty minutes was fatal to anthrax spores, but those of a certain short and thick bacillus found in garden soil were only killed when the temperature was maintained at 105° for twenty minutes.

The question as to the practicability of destroying spores in the interior of packages—rolls of blankets, etc., has received the attention of the experimenters last mentioned, and will doubtless be considered by my colleagues of the Committee on Disinfectants, whose province it is to take account of the various points which may arise relating to the practical use of approved disinfecting agents.

[1] Mitt. a. d. Kaiserlichen Gesundheitsamte, vol. I. pp. 322–40.

From the experimental evidence presented, it is safe to say that:

The temperature of boiling water will quickly destroy the vitality of all microörganisms of the class to which known disease germs belong, in the absence of spores.

Steam at a temperature of 110° C. (221° F.) maintained for one or two minutes, or of 105° C. (230° F.) maintained for ten minutes, will infallibly destroy the spores of bacilli, which constitute the most difficult test of disinfecting power known.

Note.—I desire to call attention to the close correspondence between the thermal death-point of micrococci as fixed by my experiments, viz., 140° F. for ten minutes, and the results obtained by the authors quoted by Dr. Rohé in the preceding paper, in the disinfection—*i. e.*, destruction of specific infecting power—of fresh vaccine virus by similar low temperatures. Certainly this correspondence gives some support to the supposition that infective virulence is due to the presence of the micrococcus found in vaccine lymph, although the etiological role of this micrococcus has never been demonstrated by successful inoculations with pure cultures.

SECONDARY NERVE SUTURE.[1]

By THOMAS M. MARKOE, M.D.,
of New York.

It has long been known that divided nerves would, under favorable conditions, unite with restoration, more or less complete, of the functions which had been abrogated by the injury. Indeed, this fact has played a prominent part in the results of the operations which have been performed on nerves the seats of neuralgia, where it has been sought to cure the pain by abolishing the sensibility of the affected nerve by separating it by section from its trophic centre. These operations, as is well known, though giving temporary relief, have commonly failed to be of permanent benefit, because the divided nerves, after a certain lapse of time, have reunited, with re-establishment of function, which has announced itself by a return of the pain in all its original severity. To avoid this disappointing result, operators have been at much pains to prevent, if possible, the reunion of the divided trunk, and various devices have been resorted to for this purpose. Sometimes considerable portions of the nerve have been removed, sometimes a loop of the exsected nerve has been doubled back at each cut extremity, and some have fastened back these loops by sutures or ligatures. Some have modified this procedure where the trunk was easily accessible by burying the looped ends deeply in the surrounding tissues, and sometimes foreign bodies have been interposed between the divided ends to keep them separate until the disposition to unite should disappear. In spite of all these precautions, it has not been possible, in certain cases, to prevent a recurrence of the neuralgic disorder, a recurrence which, it is generally believed, and in some instances has been proved to be associated with a union, and sometimes with an extensive regeneration of the injured nerve. Examination of nerve-trunks which have undergone this regeneration, have shown the nerve-tubules perfectly restored in their continuity, and but little changed from their normal condition.

Such facts as these led very naturally to the hope that nerves accidentally divided, and where restoration of function has not occurred, might be restored to their normal powers of transmitting sensory and motor impressions by exposing the injured trunk and bringing together by suture the divided ends. This operation is not by any means a new one. It was done by Arnemann in 1826, and by Flourens in 1828, and it is stated that it was practised by Dupuytren in several instances at l'Hôtel Dieu. It was not, however, until after the elaborate researches of Augustus Waller, which were published in the Comptes Rendus of the Academy of Sciences of Paris, in the year 1852, that the operation was placed on a scientific basis. He showed, by means of experiments on animals, the whole history of degeneration and regeneration of nerves after injury so completely that he has left scarcely anything to be done by his successors; and, encouraged and guided by his discoveries, surgeons have performed the operation of the suture of divided nerves in a large number of cases in England, on the Continent, and in this country, with a success generally extremely satisfactory, though it must be acknowleged not equally as uniformly so. The operation has been done, in certain instances, immediately on the receipt of the injury, while the cut surfaces were yet fresh; and it has been done as a secondary operation weeks, months, and even years after the original accident, thus dividing the operations into two classes—the primary and the secondary. It is of the latter only, the secondary operation, that I propose to speak this evening.

I have had the opportunity of performing the operation in two cases, of which the histories are as follows:

Valentine Keller, æt. 36, a German, was brought into the New York Hospital, December 25, 1883, with a stab wound of the left arm. The wound was situated on the external aspect of the arm, about two inches above the external condyle of the humerus. It was not more than half an inch long, but the blade of the instrument had penetrated so far as nearly to transfix the limb, grazing in its course the anterior face of the bone. It was noticed that there was no pulsation at the wrist. A counter-opening was made at the point where the wound approached the skin on the inner side of the arm, and a fenestrated drainage-tube passed from one opening to the other. The day after his admission, without any apparent cause, profuse arterial hemorrhage took place. The wound on the outside was enlarged, and the brachial tied above and below the wounded point. No further hemorrhage occurred, but the loss of blood had been so great as to bring on a condition of collapse which was very alarming. Transfusion with a saline fluid was promptly resorted to, and gradually the patient rallied. The wound

[1] Read before the New York Surgical Society, Feb. 24, 1885.

healed slowly, mainly by granulation, and cicatrization was not complete till the end of January. On the 20th of January, attention was called to the fact that paralysis, both of sensation and motion, existed in the parts supplied by the musculo-spiral nerve. There was loss of the power of extension of the hand, flexion of the hand not impaired. There was loss of extension of the fingers, flexion remaining perfect. Motions at elbow-joint perfect. Anæsthesia, but not complete, existed over dorsal surface of thumb, index, and middle fingers, with a good deal of burning pain. He had now recovered his general health, but no improvement could be discovered in the paralyzed parts, though electricity and massage were daily and faithfully employed. He suffered so much from the causalgia, that trophic disturbances in the muscles and skin were beginning to show themselves so distinctly that suture of the nerve was decided upon, and performed on the 9th of February, forty-six days after the receipt of the wound.

An incision was made along the course of the musculo-spiral nerve, having the scar of the wound as its centre. A good deal of cicatricial tissue was encountered in passing down between the brachialis anticus and the supinator longus, but when the nerve was reached it was found to be free and distinct above and below the point of injury, and was without much difficulty isolated from the cicatricial mass and cut off clean with a pair of sharp scissors. By flexing the arm, the divided ends could be easily brought together, and the two were united by two slender catgut sutures passing through the substance of the nerve. The signs of degeneration of either end were not distinct. The wound was carefully closed, and the forearm left flexed at about a right angle with the arm.

February 10.—Complaining of much pain in the wound, but says he feels it radiating down the limb, along the musculo-spiral distribution, mostly on the dorsum of the thumb and the index finger. This pain was regarded as a favorable sign, and, it was hoped, would be the precursor of rapid restoration of lost power. This expectation, however, was not realized; the pain gradually subsided, and then disappeared altogether, the wound meanwhile healing well, mostly by primary union. By the time the operation was performed, the man had recovered his health and strength, and seemed to be in as good a condition as could be desired for its success. Electricity and massage were employed daily, and he was encouraged to use the arm as much as possible. The faradic current caused no response; the galvanic produced at first some contraction, but this soon ceased entirely. The affected muscles were flabby, but not appreciably atrophied. He was kept under observation, and treatment was sedulously continued, when, on the 14th of April, at his own request, he was discharged from the hospital. At this time there was no apparent improvement in the condition of the paralyzed muscles. The conditions as to sensibility were not noted. The hand and fingers were perfectly powerless as far as extension was concerned, and the member was therefore practically useless. I explained to him that restoration of function was often long delayed in these cases, and encouraged him to use all the muscles of the limb that were capable of acting, and in particular I urged him constantly to direct his will along the paralyzed cord, and try to make the muscles respond to their natural stimulus. I heard nothing more from him, except that he was under Dr. McBride's care in the out-patient department of the hospital, and was not improving. Recently, however, I have received a note from Dr. McBride, saying that Dr. S. O. Vanderpoel, Jr., who had acted in his absence, had reported to him that the man had so far recovered the use of the limb as to be able to go to work.

I saw him on the first of February, and found that he had regained the use of the paralyzed muscles so far that he could extend the hand and fingers, and supinate the hand almost to the full extent and with a good deal of power. The action could not be performed rapidly as yet, or completely, owing, no doubt, to the stiffness of the joints concerned from prolonged disuse. He is conscious of daily improvement, both in strength and facility of movement. The muscles can be felt to contract under the finger and have regained their normal bulk and firmness.

The second case was, to me, one of unusual interest, as I had no experience either of my own or of others to guide me in diagnosis, prognosis, or treatment. I believe the case to be unique in the history of surgery.

Lillie Dougherty, æt. 5 years, was admitted to the New York Hospital October 22, 1884, with a wound of the neck, inflicted by a sharp, clean instrument a short time before her admission. There was found an irregular wound extending from the nucha on the left side, opposite the fourth cervical vertebra, passing obliquely downward and forward to the posterior border of the sterno-cleido-mastoid muscle, and stopping about an inch above the upper margin of the clavicle. The sterno-mastoid and the trapezius were both partly divided. Considerable hemorrhage had occurred, but no vessel required a ligature. The child was slender in form, pale and delicate in appearance, but in good health as far as could be ascertained. The wound was brought together carefully, treated antiseptically, and healed, partly by granulation, in about a month. Soon after the injury, October 30, it was noticed that she was unable to raise her right arm from the side, and gradually as the disability of the shoulder from the wound subsided, it became evident that a certain amount of paralysis existed, unquestionably dependent upon some nerve injury inflicted in the depth of the wound. There was no nerve trunk in the course of the wound whose division could account for the paralysis, and in point of fact nothing but a wound of some part of the brachial plexus was competent to explain the symptoms presented, and this idea was rejected by me at first, and for two reasons: First, the wound did not appear deep enough to reach any part of the brachial plexus, and, second, the line of incision in the neck seemed to be entirely above the course of the fifth cervical nerve which forms the uppermost cord of the plexus. On carefully studying the conditions, however, I finally reached a positive diagnosis, becoming convinced that nothing could have happened in such a wound,

except as severing the upper cord of the brachial plexus could afford an explanation of the symptoms presented.

These symptoms were loss of power of abduction of the arm and of flexion of the forearm upon the arm. Supination was limited and feeble. Pronation good. Extension of forearm slightly, if at all, affected. Flexion and extension of hand and fingers not notably impaired. Anæsthesia well marked over the shoulder and outer aspect of arm. By the time that cicatrization of the wound had taken place, about the first of December, these signs of paralysis had become perfectly distinct, and it was also noted that atrophy was beginning, and was in fact well marked in the deltoid, and supra and infra-spinatus muscles, and less distinctly in the biceps and brachialis anticus.

She was placed upon tonic and invigorating treatment and regimen, and everything was done to improve and maintain her general health. Faradization of the affected muscles and friction of all the shoulder and arm was continued daily, but without any manifest results. The general condition improved very much to our satisfaction; she was very tractable and obedient in seconding our efforts to make her use her arm and shoulder muscles as far as her will had any control over them. No improvement could be discovered, the arm hung useless by her side, and when she wanted to play with her dolls she had to lift the palsied arm on to her lap with the other hand, and then she could use the fingers to hold it.

On the 8th of December a careful examination of the reaction under galvanic and faradic currents was made with the following results:

Muscles of Shoulder.

Nerve.	Muscle.	Galv. Cur'nt.	Far Cur'nt.
Spinal accessory.	Sterno-mastoid; trapezius.	Normal.	Normal. M & N absent.
Ant. thoracic.	Pectoral.	Normal.	Normal.
Subscapular.	Lat. dorsi.	Normal.	Normal.
Circumflex.	Deltoid.	Normal; increased when applied to muscle direct reaction of degeneration.	Absent; muscle atrophied.
	Muscles of Arm.		
Musc. cutan.	Biceps; brachialis anticus.	Normal; increased when applied to muscles; direct reaction of degen.	Absent to M & N; atrophy of muscles.
Mus. spiral.	Triceps; supin. longus.	Normal.	Normal or slightly diminished.

The reaction of the muscles supplied by the rhomboid, suprascapular, and long thoracic nerves could not be satisfactorily obtained, but the muscles themselves showed marked atrophy. The muscles of the forearm were not involved.

The faradic current was now replaced by the galvanic, which was applied daily. No improvement in muscular reaction. Atrophy of shoulder muscles appears more marked. Her general condition is greatly improved. She is in good spirits, eats and sleeps well, and presents the appearance and demeanor of a child in good health.

That the most careful study of the paralyzed muscles alone would have warranted a diagnosis as to the precise point of injury, I am not prepared to assert. Taking, however, all the points as they have been presented above, and associating them with a careful topographical survey of the line of the wound, there seems to be but one conclusion to which all the facts pointed, and that conclusion marked the fifth cervical nerve, which is the first or upper cord of the brachial plexus, as the seat of the injury, and in consultation with my colleagues it was deemed right to make an attempt to suture the wounded cord in the hope of restoring the functions of a limb in its present condition absolutely useless. In view of the fact, however, that these injuries to nerve trunks do sometimes recover spontaneously it was thought best to wait, before undertaking any operation, until it should become quite certain that nature was unable to effect a cure. Accordingly, treatment was steadily persevered in until the beginning of March, when, no improvement being perceptible, it was deemed justifiable to try what surgery could do to bring relief.

The operation was done March 2, 1884, one hundred and thirty-one days after the infliction of the wound. An incision was made along a line corresponding to the upper part and outer margin of the brachial plexus, and carefully followed down until this border of the plexus was reached. The cicatricial tissue was very extensive, and very confusing, as we tried to recognize the anatomical landmarks, and a very careful and tedious dissection was necessary before we clearly recognized the nerve cord involved in the wound. Finally, however, the nerve-trunk above and below the wound could be distinctly seen, and was isolated sufficiently to enable us to trace its whole length from the point of its emergence from the intervertebral foramen to the point where it joins the plexus below. We were extremely careful not to handle roughly, or to pinch with forceps, any part of the exposed nerve, and this it was that so greatly prolonged an already very tedious operation. The cord, which was now seen to be the upper root of the plexus, as we had originally supposed, was divided in two places with sharp scissors, so as to include all that part involved in the cicatrix, leaving a clear cut on both distal and proximal ends through healthy nerve substance. I say healthy nerve substance, but it became evident, on making the section, what I suspected when the nerve was first exposed, that the distal portion beyond the cut was in a condition of physiological integrity, while the short portion, less than an inch in length, which formed the proximal stump, was manifestly smaller, its fibres not so clean and glistening as in the cord below and in the surrounding nervous trunks. In short, it was the proximal, and not the distal, portion of the cut nerve which had undergone the classical degeneration, the

distal portion retaining almost perfectly its normal appearance. I very much regret that I cannot make this statement with the authority which would give it value as a scientific fact; for, unfortunately, no microscopic examination of the cut ends was made, and I am well aware that the gross appearances, though very distinct, would not alone be reliable evidence as to the condition of the nerve-tubules. Two very fine catgut sutures were now passed through the cut ends and tied, not very tightly. Some strain on the suture was easily overcome by flexing the head on the trunk, and drawing it toward the left side. In this position it was secured by bandages. The wound was dressed with iodoform and sublimate gauze, and behaved perfectly well, though not healing entirely by primary adhesion. By the 14th of March the wound was cicatrized, and she soon regained her usual condition of health. Convalescence was delayed by a pretty threatening attack of purulent conjunctivitis, which at one time seriously threatened the cornea. This, however, passed safely by, with no corneal damage, and no further complication occurred. The electrical treatment was resumed, and continued during the remainder of her stay in the hospital. No improvement followed the aspiration, and at the time of her discharge the condition of the muscles, both with regard to electrical reaction and voluntary motion, was just what it had been before the operation, saving that the atrophy, particularly of the deltoid, was more than ever conspicuous.

During the summer, she was taken to the country, and seemed in all respects quite well, but no change in the paralyzed parts was noticed until about the first of October, when slight voluntary motion began to show itself, which slowly but steadily improved. About the middle of January she was brought to my office, and I was delighted to find that she could flex the forearm upon the hand, and could abduct the arm from the side, during which movements the muscles could be felt contracting and hardening under the finger placed upon them. The shoulder had recovered its rounded contour and the flexor muscles had become markedly developed. In short, the evidences of atrophy had disappeared, and the indications of voluntary power were daily increasing. On the 21st of February I saw her again, and found the extent and power of muscular motion surprisingly increased. The case promises to prove a complete success.

The study of this whole subject during the last fifty years has led to some important and very interesting discoveries as to the behavior of nerves under and after severe injury. In the first place, it has been shown that, after complete section of a nerve-trunk, there ensues a degeneration of all that part of the nerve beyond the point of severance which extends throughout the whole distribution of the cut nerves, and is so complete that, according to most observers, all trace of original nerve tissue is lost. There is, however, considerable discrepancy of opinion as to the completeness of this destruction, some contending that it is absolute and entire, others believing that the sheaths of Schwann and the axis-cylinder never entirely disappear. That nerves thus degenerated after section was known long before his time, but Augustus Waller, in 1852, by his admirable and ingenious experiments, brought out all the facts connected with both the degeneration and regeneration of nerves so completely that scarcely anything of importance has been added to the history of the process since his time. The changes, as described by Ranvier, are about as follows: The experiments being conducted on cats and dogs, it was found that after section of a nerve the distal segment began to show signs of change as early as the first day. The myelin begins to disintegrate, and by the fourth to the sixth day has mainly disappeared, leaving the sheaths of Schwann filled with fine fatty granules. The axis-cylinder has also by this time, according to his observations, entirely disappeared. By the twentieth day, the sheaths of Schwann have become empty, and this he considers to mark the extreme point of degeneration, from this condition very little change being observed. A similar degeneration is noticed to begin at the cut extremity of the proximal end, but only reaches for a line or two from the end of the nerve and then ceases, the axis-cylinder remaining unchanged. This disintegration is now followed, after a varying interval, by a regeneration by which, in favorable circumstances, the altered nerve is restored to its normal condition and functions. This change consists in a reversal of the steps which the nerve took in its degeneration. The sheaths of Schwann, which, according to this observer, never entirely disappear, begin again to be filled out with a granular substance which soon assumes the character of myelin, the axis-cylinder makes its reappearance, and, in short, the atrophied and shrunken cord gradually assumes the appearance, and nearly the dimensions, of the original nerve. While this reformation of the nerve-tubules is going on, the union of the cut ends is being accomplished. By about the twentieth day fine delicate fibres begin to sprout from the proximal end into the cicatricial tissue which surrounds it, and gradually developing themselves in size and perfection of organization, shoot through the intervening bond of union till they encounter the distal end, with which they amalgamate themselves. Finally, if the ends are in good apposition, the cicatricial bond of union is occupied and displaced by newly formed nerve which joins the two into one continuous cord, in which the individual nerve-fibres are almost perfect imitations, perhaps on a slightly reduced scale, of the original nerve elements. In the animals, experiments on the repair was not perfected until about six months had elapsed. In man, it is probable that the period of perfect restoration is longer, but no accurate knowledge on this point has been attained.

Another of the effects of nerve section which has of late engaged the earnest attention of both physiologists and practical surgeons, is the paralysis of motion and sensation which usually follows a complete section of a nerve-trunk. I say usually, because the results of nerve division are by no means uniform or constant. There are reported, for example, a certain number of cases in which, after complete section of a nerve-trunk, no loss of sensibility could be detected in the parts supplied

by it, and a certain number of others in which sensibility being momentarily suspended, has been regained in a period so short as to make the immediate and perfect union of the divided ends the only explanation possible of the rapid restoration of nerve power. Still further, it is constantly noticed that anæsthesia following a divided nerve-trunk does not by any means accurately correspond with the area of distribution of the branches of that trunk, but is much less extensive than it should be, anatomically speaking, sometimes occupying only a small part of the region, the whole of which we should expect, *a priori*, would be affected. To the explanation of these facts much attention has been given by German and French observers; and much careful research has been expended, with the result of having some of the phenomena not as precisely accounted for as might be desirable.

The first mode of explaining these facts of the limited area of anæsthesia and the rapid return of sensibility is by invoking the aid of anastomosis. That anastomosis in the ordinary acceptation of the term does not exist among the nerves is conceded. It has been demonstrated by Waller that the nerve-tubules individually are continuous from the point of their central origin to the point of their final distribution, and that no communication exists between the myelin in these tubules, and that therefore one tubule cannot take up the function of a neighboring one which has been injured. It has been clearly shown, however, by the elaborate experiments of Arloing and Tripier, that, in the cat and dog, and in the horse and ass, there are certain tubules which pass from one nerve to another in a continuous or in a reverse direction, to be lost on the nerve to which they have attached themselves at a varying distance on the adopted trunk. These intercommunications are found first in the plexuses, where they are probably very frequent; second, in the branches which are known to pass from one nerve-trunk to another in the course of its distribution, such as those that pass between the medial and radial, and the anastomotic twig that joins the ulnar and the internal cutaneous. The most abundant anastomosis, however, is found near the peripheral termination of the nerves where all the terminal twigs unite to form the network of final distribution. Another explanation of the partial and limited anæsthesia which sometimes follows nerve section, is found by some in the belief that there may be such a thing as the immediate union of the divided ends with immediate restoration of function. This belief is entertained by such men as Schiff, Gluck, Tillmans, Paget, and more recently by Caput and Wolberg, who consider that this primary union is so prompt and complete that no degeneration of the distal fibres can take place; while, on the other hand, it is held to be untenable, because unproved, by such observers as Nicaise, Weir Mitchell, Letievant, Brown-Sèquard, and indeed by the great majority of the most distinguished experimenters. These observations as to the limitations of paralysis after section do not apply quite so commonly to lesions of motility. Here the conditions seem to be somewhat different. The effect of section here seems to be, almost uniformly, a complete motor paralysis, followed pretty early by muscular atrophy, which continues until the function of the nerve is restored by its union. Letievant has, however, called attention to the fact that even here there is room for deception, the associate muscles not paralyzed acting so as in a measure to supply the deficiency of those that are paralyzed, so as to give to the whole group what he calls supplemental motility, which may easily mislead the careless observer. This error is easily avoided by applying the electrical test and by noting the atrophy which is sure to develop itself soon after the nerve supply is cut off. These electrical tests are exceedingly valuable in all stages of these injuries, and may be furnished by both the faradic and the galvanic currents, applied either to the cut end of the nerve or to the skin over the belly of the affected muscle. It is noticed that the electrical current applied, in either way, soon after section causes a feeble contraction of the palsied muscles, but that this contraction grows less and less from day to day as the muscular fibre is undergoing disorganization, and finally ceases altogether, the strongest current producing no response. A curious fact is observed in connection with these electrical tests. It is thus expressed by Nicaise: "The faradization curve during the first fifteen days becomes gradually depressed. After the third week the muscle is no longer excitable, at least through the skin. Towards the sixth week, in favorable cases, the excitability reappears and gradually increases until it reaches the normal reaction. The galvanization curve follows an entirely different course. During the first fifteen days it follows the faradization curve; but from the third week, when the interrupted currents have no longer any effect, the galvanic reaction becomes exaggerated, the curve is raised, soon exceeding the normal, and reaches its maximum when the other is at its minimum. At the moment when repair begins to take place the galvanic phenomena follow an inverse order; at the same time that the faradic current is raised, the galvanic curve is lowered, and both gradually return to the normal level." This is what is spoken of as the reaction of degeneration by the German authors.

With regard to the facts of compensatory nerve supply, after section of a trunk, there can be no doubt, as the facts are so common and so easily observed; but as to the part which anastomosis takes in this return of function, our knowledge can hardly be said to have assumed a positive character. For example, the experiment by Arloing and Tripier, in which each of the four nerves going to a toe in the dog's paw were successively divided, with the result that no insensibility to pain followed the division of the first nerve, and none followed the second, and none the third; but when the fourth was cut, complete anæsthesia was immediately produced, seems to indicate so perfect a communication between the different nerves at some part of their course that we can hardly understand why, if this communication is always present, a severed nerve should show any signs whatever of paralysis.

Another point in the anastomotic theory, which

at first seems hard to comprehend, has reference to the communicating branches which join together some of the larger trunks. In these there has been shown to be fibres which pass from one trunk to another, recurring toward the cerebral centres, when they reach the trunk to which they are destined, and reaching a certain distance up this trunk towards its point of origin. Now, as far as we know, nerves in their normal condition transmit impressions only in one direction—*i. e.*, the sensory nerves send their current from the periphery to the centre, while the motor fibres bring the mandates of the central organ to the muscles at the periphery. If, therefore, there is to be any anastomotic current supplied through these recurrent fibres, the nervous impulse must pass along the nerve in a reverse direction to that which it originally followed. This is a fair objection to this part of the theory, and at first sight seems well taken. The well-known and ingenious experiment of M. Paul Bert, I think, fully answers the objection. M. Bert made an incision along the back of a rat, and then, having denuded the end of the tail of its skin, placed the tail thus denuded in the incision in the back where it adhered firmly. After the union had become firm, he cut off the tail at its root, leaving its end adherent to the back. Now, upon irritating the tail at its root, evidences of sensibility to pain were distinctly manifested, showing that a nerve under altered circumstances could convey impulses in a reversed direction, very much as a telegraph wire can convey messages in both directions.

Of the technique of these operations, but little requires to be said. The injured nerve-trunks are usually superficial, and therefore easily accessible. In the operations which I have done, the main difficulties have been, first, the finding and identifying the distal atrophied extremity; and, second, the disentangling without bruising or laceration of the cut ends from the cicatricial tissue by which they are surrounded, and with which they are apt to be very closely incorporated. Both these proceedings require great delicacy in handling, and great patience in unravelling the slender and fragile fibres, and in extricating them unharmed from the tough and unyielding cicatrix in which they are buried. Another difficulty which I encountered in the neck case was the misleading effect of the cicatricial tissue when I was trying to follow down the areolar interspaces in order to arrive at the injured nerve. So utter was the confusion of layers that, although I had rehearsed the operation many times on the cadaver, I found myself wandering so far from my course that I was well over toward the jugular vein before I could be sure of my landmarks. The two ends of the divided nerve being exposed, the extremity of each is to be severed with a pair of sharp scissors, taking care to go sufficiently high to reach original nerve tissue, and at the same time being careful to avoid cutting away more than is necessary, lest the tension be increased when the ends are brought together. In one of my cases, that of the arm, microscopic examination showed no trace of nerve fibre in the part cut away by the scissors, proving that my section had not reached the real nerve end. This I think unfortunate, and must always delay, and probably sometimes defeat, the object of the operation. Various sutures have been used to join the cut ends, but opinion seems to have settled upon catgut, as fine as is consistent with strength. The shape of the needle is not unimportant. A common round cambric needle is the best, making its way through the tissues by displacement rather than by cutting. Wolberg recommends a flat needle, shaped like a sabre, but without cutting edge. Some are careful not to pass the needle through the substance of the nerve for fear of injuring the tubules. Most operators prefer to pass the suture through the body of the nerve, as securing a stronger hold. Some cut the two ends obliquely so as to make flaps, which, being applied to one another, afford an increased surface of contact. Rawa brings the ends together side by side and then surrounds them and binds them together with a catgut ligature. When much loss of substance has occurred, and the ends cannot be made to touch, Vanlear has suggested placing the ends in a Neuber's drainage-tube, and with catgut threads attached to each end of the nerve, drawing them as near as possible together within the tube, and leaving the space between the ends to be filled up by the reparative material. In a case in which he found it impossible to bring the ends in apposition, Löbker resected the bones of the forearm, thus shortening the limb so that the ends could be approximated without tension. In an experiment, Gluck transferred a rabbit's nerve to the limb of a chicken with success; and on the human subject, Albert replaced an exsected nerve with a segment of nerve taken from a recently amputated limb.

The nerve ends being brought securely together, great care is to be taken by position of limb that no tension should occur. The wound should be brought together so as to secure primary union if possible, as the healing by granulation is believed to exercise a very unfavorable influence on the result, particularly if it be long delayed, or accompanied by much suppuration.

The time at which return of sensation takes place is very variable, in some cases sensibility being well marked in a few days, in others not until months or even years have elapsed. It is sometimes noticed, as in my musculo-spiral case, that, very soon after suture, a painful sensation pervades all the branches of distribution of the severed nerve, and this is sometimes the precursor of a healthy restoration of sensibility. It is not so always, however, but sometimes gradually subsides, leaving the parts in their original, more or less perfect insensitiveness. The return of motility is commonly longer delayed than the return of sensibility. Here we have not only the degeneration of the nerve, but degeneration of muscular fibre to be overcome, and accordingly this paralysis is not only more slowly recovered from, but much more frequently remains a permanent disablement. It will be noticed that, in this communication, I have scarcely alluded to the trophic changes which are so certain to ensue after nerve section. This has not been because I undervalued these changes, either in their clinical

or scientific aspects. It is simply because in the two cases which have been the basis of my studies these trophic changes never assumed any prominence.

With regard to the results of the operations that have been put on record, the most recent and best tabular statement is found in Weissenstein's article on secondary nerve suture in Brun's *Chirurgischen Klinik*, 1884. He gives the results of thirty-three cases, from all sources, in which the operation has been done at varying periods after nerve injury, in almost every case after the original wound had healed. To these thirty-three cases I have been able to add—

1. Dr. W. S. Halsted's case. B., aged 22 years, injured by glass. Degenerative reaction of muscles and complete loss of sensation in the regions supplied by the median and ulnar nerves at the time of the eighth month after injury. Separation after paring off nerve ends about three inches. Neuro-plastic suture of median and direct suture of the ulnar, with relaxation sutures in both. Strong flexion of hand and forearm, and still some tension. The wound healed by primary union. No benefit six months after the operation.

2. By Dr. Weir, wound of sciatic nerve nine years previously, operated on December, 1882; catgut sutures. By suturing adjacent tissues, and flexing knee forcibly, approximation was obtained. No improvement in motility, but gain in general sensation, and great improvement in trophic changes, which had advanced to ulceration. The ulcers all healed and local nutrition generally improved.

3. A case operated on by Dr. W. T. Bull in July, 1883. It was a case of wound of median and ulnar nerves with corresponding paralysis. The suture of both nerves with catgut was done about seven weeks after injury. Was discharged from the hospital about five weeks after operation, with both sensation and motility beginning to return and improving daily.

4. A case reported by Dr. Roswell Park, of Chicago, in which the radial was sutured with catgut sixteen days after its division. The recovery was rapid, the patient being considered well in six weeks.

5. Case reported by me above, of musculo-spiral suture forty-six days after wound. Catgut suture, recovery of sensation and motion, with a useful limb. Daily improving.

6. Case reported above of suture of upper cord of brachial plexus, one hundred and thirty-one days after its division. Recovery of sensation and motion and nutritive condition, daily becoming more perfect.

These six cases added to Weissenstein's thirty-three, make in all thirty-nine cases. Of these, twenty-nine were successes, in so far that sensibility and motility were at least partly recovered. In six cases no improvement, or almost none occurred, and in three cases the data were insufficient for statistical use. The dates of improvement can be given approximately thus: Traces of sensibility were noted in from two to four weeks. Traces of motility in from sixteen days to sixty, in two cases more than a year. Complete restoration of muscle function was marked in one case as occurring in twenty-six days; in several cases not till the lapse of one or even more years. All the authors seem to agree that electricity and massage greatly favored the return of function in the paralyzed parts. If now we consider that three-quarters of all the reported cases were more or less successful, and still further consider that many of the cases were reported so soon after operation that the full results had not yet been realized; I think we are warranted in concluding that the proceeding promises a degree of success which we can count upon in very few of the operations which we are every day performing. When we take into account the serious and permanent disability for the cure of which the operation is recommended, the entire freedom from danger to life, and the large measure of success which has followed its performance, we are entitled, I think, to regard it as one of the best and most useful contributions to modern surgery.

ON THE USE OF BICHLORIDE OF MERCURY IN PHTHISIS.

By P. C. KALLOCH, M.D.,
ASSISTANT SURGEON, U. S. MARINE-HOSPITAL SERVICE.

The bichloride of mercury is not, I believe, in general use as a remedy in phthisis pulmonalis, but is, I think, of sufficient value to merit further investigation.

The only article written upon the subject that has come to my notice was that of Andrew H. Smith, M.D., of New York, in the *Medical Record* of September 20, 1884, in which he spoke of some experiments with the drug for the purpose of ascertaining the maximum dose that could be safely given, evidently with the idea of producing a favorable effect, by the germicidal action which the medicine is known to possess.

I have not used it with the same purpose in view, but rather with the expectation of promoting the action of the lymphatic system in removing deleterious matter from the blood and system at large, and of improving the quality of the blood.

Prof. Bartholow, in his *Materia Medica*, says that

> "Mercury increases the number of red corpuscles, and improves the quality of the blood, providing it be given in small quantities, not often repeated, but any considerable quantity administered a sufficient time will affect the quality and composition of the blood: the red corpuscles are diminished in number, the fibrin loses its plasticity, the proportion of water is increased, and various effete materials, whose nature is unknown, accumulate.
>
> "The metal has a selective action on the lymphatic system."

I am of the opinion that the lymphatic system is largely at fault in phthisis, and, indeed, the theory, that phthisis and scrofula are identical, is a very prevalent one.

I have, therefore, not considered the part taken by the bacillus tuberculosis in the use of this remedy, being first induced to use it, by noting its good effect in a case of suspected syphilitic phthisis.

I have used the following prescription, at times slightly modified, in thirty-three cases of phthisis, twenty of which were treated in hospital, the remain-

ing number as office cases, most of the latter being in the incipient stage of the disease:

R.—Hydrarg. bichlorid. . . . . gr. j.
Ammonium chloride . . . . ℥iiss.
Alcohol . . . . . f℥ij.
Glycerine and water to make f℥iv.

Of this, a teaspoonful was given after each meal, well diluted.

In addition to this, I have usually prescribed an embrocation of oleum morrhuæ and oleum terebinthinæ, to be used over the chest twice daily.

The result has been, I believe, in every case (with the exception of one of laryngeal phthisis, well advanced before treatment was begun, which ended fatally) most satisfactory, the symptoms improving with as much regularity as we expect in cases of malaria under the judicious use of quinine, though of course not so rapidly. I do not remember a single case (except the one noted above) under the treatment for any length of time without seeing most marked improvement in the symptoms and general condition. The most unsatisfactory feature in the use of the medicine in my hands has been the impossibility of keeping the patients in view until a final result was obtained. Those who were treated in the office, upon being relieved of the disagreeable symptoms (which I know occurred in many cases), have either neglected to return for a continuance of the treatment as directed, from carelessness, or have shipped to some part from which it was impossible to return, if they so desired. Those treated in hospital, upon reaching that point at which they were able to resume work, have in almost every case shipped and have not again been seen. This renders a report of the changes in physical signs impossible, as such changes are necessarily slow. I have, however, used the remedy sufficiently to be convinced that its effects are more satisfactory than those of any other drug, or combination of drugs, with which I am acquainted for tubercular affections.

The final result of the treatment, if it could be followed as long as desired, I have not been in a position to determine, although in three hospital cases, two of them possibly syphilitic, the cough has entirely stopped, flesh and strength have been gained, and the patients have resumed their employment. Only one of these at the present time has any symptoms of chest trouble, and he coughs only upon fresh attacks of cold. They all present some dulness by percussion of the chest and some want of normal vesicular breathing. These signs, I hope, will gradually disappear.

I will briefly notice the following cases in which the action of the medicine has been especially favorable:

Case I.—John Silva, aged 48 years, nativity West Indies, occupation seaman, admitted to the Marine Ward, City Hospital, November 13, 1884, is still remaining under treatment.

When admitted, he was suffering principally from diarrhœa, which had existed some length of time, and doubtless of a tuberculous character. He was extremely emaciated, had a troublesome cough, and was confined to bed for some time after being admitted. He had dulness at the apices of both lungs on percussion, with feeble breath-sounds over the upper lobes of both lungs. Under the treatment spoken of above, the diarrhœa very soon ceased to be troublesome, the cough has been remarkably improved, he has gained in flesh and strength, and if the improvement continues, will soon be able to ship again. An interesting feature of the case was a tympanitic distention of the abdomen, which came on about a month ago, during a time when the bichloride was not being used. This swelling during the last ten days, under the hypodermic use of the remedy, has steadily disappeared, the improvement, I think, being due to its action on the lymphatic glands of the intestines.

Case II.—Vicenta Tanda, aged 23 years, native of Spain, occupation seaman, was admitted to hospital December 22, 1884; discharged January 10, 1885. He has been at odd times under treatment as an office patient for phthisis, but neglected to return for medicine, not having received treatment since October 18, 1884. When admitted to the hospital he presented a distressed and shrunken face, of a pale bluish, unhealthy color, with heavy dark lines, and depressions under the eyes, glands in the submaxillary region indurated, painful, and the size of walnuts, a very troublesome, hoarse cough, and considerable expectoration of a tenacious character. His appetite was very poor; he was weak and emaciated. Dulness on percussion was noted over both lungs, generally distributed, and a corresponding lack of vesicular sounds on auscultation. Within three days of the time when treatment was begun (the bichloride hypodermically, and oil externally) a considerable change for the better was noticed, and when discharged, after twenty-one days of treatment, he looked and felt like a different man, the cough and other troublesome symptoms having disappeared to a remarkable degree.

Case III.—Andrew Taylor, aged 45 years, colored, was admitted to the City ward of the hospital, not being a patient of the Service, in June, 1884. He was in the last stage of consumption, delirious, extremely feeble in strength, with some fever, and was confined to bed.

The patient, under the bichloride $\frac{1}{32}$ grain, began at once to improve; in a few days was sitting up, and in about three weeks went home of his own accord.

From my experience in the administration of this drug in phthisis, I am of the opinion that if given internally, its dose should be not greater than $\frac{1}{32}$ grain three times a day, or only twice a day if it is to be continued for more than two weeks without an intermission. I believe it is better not to produce any of the characteristic toxic or inflammatory symptoms which follow the prolonged or over-administration of the remedy. I have recently, in a few cases, substituted the hypodermic for the internal method of giving it, and, from a limited experience, think the former has some advantages which the latter has not. It is, however, quite painful when used w th the needle, so much so that it would be hard work to induce many patients to submit to it for any length of time. The albuminate, made with the

corrosive sublimate and the white of egg, is less painful than the solution in water or alcohol.

Since the above was written, I have added to the albuminate injection, for the purpose of relieving pain, in one case, two drops, in another, four drops, of a two per cent. solution of hydrochlorate of cocaine, with the following result: In the first case the pain did not begin until an hour after the injection, lasted but one hour, and was less severe than usual. In the case in which four drops were used the patient reported very much less pain than on previous occasions.

If the hypodermic should prove the more valuable method of administration, the cocaine may, to a large extent, remove the principal objection to its use in that way.

MEDICAL PROGRESS.

Chinolin as a Remedy in Diphtheria.—Dr. Jul. Donath, in the *Wiener med. Presse*, of January 18, 1885, after reviewing the results reported by numerous physicians on chinolin as a remedy in diphtheria, and which are in the main favorable, gives his own conclusions as follows. Notwithstanding its favorable effect upon the local manifestation of the disease, it does not in all cases exert a similar beneficial influence upon the general infection, of which the most reliable symptom is the appearance of albumen in the urine. Whether the sequelæ and complications of the disease are less severe under the chinolin treatment, Dr. Donath is unable to decide. However, in no case in which the remedy was used, did the disease attack the larynx, nor to any extent, worthy of mention, invade the nose, or reach the middle ear through the Eustachian tube. Further, it is worthy of note that the mortality of the disease was, in the same epidemic, before the employment of chinolin, 35.2 per cent., and after its introduction 16.6 per cent. It, therefore, appears worthy of further trial.

Suggestions as to the Operation of Abdominal Section.—Dr. Thomas Savage, in *The British Medical Journal* of Jan. 31, 1885, after reviewing a year's work in abdominal surgery, comprising one hundred and four cases with nine deaths, concludes his paper as follows: We are learning, if we have not already learnt, to look on acute peritonitis as a symptom of some organic change, and not as a disease in itself. And this is well for our patients, because operative measures can do much for it. We shall, ere long, regard so-called "idiopathic peritonitis" almost as a curiosity.

To obtain success in abdominal section, the conclusion of another year's work impresses upon me more and more forcibly the importance of insuring that the peritoneum shall be kept "clean and dry." There must be in many cases a certain amount of oozing, which will become absorbed; and I always feel happier when I think there will be little or none. But much more dangerous than this are the small escapes, during the operation, of fluid or blood, if allowed to be left behind. I think I am more particular than formerly in my sponging. A sponge deep down in Douglas's space, before adhesions are separated and blood escapes, will catch some fluid which might escape extraction afterwards. I also endeavor to press, as I proceed, a sponge or sponges into the bed out of which I have picked adherent tumors. The sponge soaks up what is effused, and, by its pressure, tends to restrain further effusion. One principal advantage from washing out the pelvis with warm water, arises from the property that the water has of floating the small clots from the deep recesses up to the surface.

I am never afraid of my sponges; I attend to them myself, and so I know the life-history, as it were, of every one of them, from the moment they leave the shop where I purchase them, until they do service in an abdominal cavity.

Rheumatic Typhlitis.—Dr. E. de Bourgarde de la Dardye, in a memoir on Rheumatic Typhlitis, establishes definitely the pathological existence of this affection, which hitherto, though not denied, has not been adequately elucidated. The conclusions of his interesting work are as follows: The rheumatic principle may be specially localized in the cæcum and produce a typhlitis which may be designated as *rheumatic*; rheumatic typhlitis is very frequently preceded or followed by rheumatic manifestations in various organs, or in the articulations; it may originate without complication of other parts, but in this case it attacks almost exclusively those who have previously been subject to other manifestations of rheumatism. Rheumatic typhlitis has special characteristics by which it may easily be distinguished from other inflammations of the cæcum; it generally is not serious, and terminates by resolution after two or three weeks.—*L' Union Médicale*, Jan. 22, 1885.

Congenital Sacral Cyst.—Dr. George R. Fowler, in the *Annals of Surgery*, for February, 1885, reports a case of congenital sacral cyst, on which he operated without success. The case is interesting as well as rare, inasmuch as examination showed the entire absence of the lower sacral vertebræ and coccyx, and, in addition, the anterior cyst wall was adherent to, or, more properly speaking, formed a part of the pelvic peritoneum.

The plan of treatment followed was the only one from which any hope of benefit could be derived, Dr. Fowler concurring with Sir Benjamin Brodie in the opinion that unless the entire growth be extirpated, it is worse than useless to attempt to operate at all.

The case affords but another example of failure due to the impossibility of definitely determining beforehand the exact attachments of the growth.

The Recent Epidemic of Cholera.—At a late meeting of the Académie de Médecine de Paris, M. Prout concluded the reading of the medical reports upon the last epidemic of cholera. The conclusions arrived at are that:

1. Cholera was imported into many of the cities and towns mentioned in the reports.

2. Water has played an important part in the transmission of the disease.

3. The intensity of the epidemic has been in direct relation with the unsanitary condition of the contaminated localities.

4. The cessation of the epidemic in infected regions

can in great part be attributed to hygenic precautions and to disinfection.—*L'Union Médicale*, Jan. 29, 1885.

ENEMATA OF TANNIN AS AN ABORTIVE OF CHOLERA.—CANTANI, in the *Gazetta degli Ospitali*, 1884, No. 86, strongly recommends injections of tannin as an abortive of cholera. This method of treatment has been tried with great success by his colleagues, the diarrhœa incident to cholera being always checked.

The formula, according to which the preparation is made, is the following:

Warm water (boiled) . . .	2 quarts.
Tannin	45 to 90 gr.
Gum arabic	℥iss.
Laudanum	30 to 50 gtt.

Cantani and his colleagues have found that the cholera infection, at least in the late epidemic, begins in the colon. This is, moreover, confirmed by the investigations of Koch—who found pathological changes principally to exist in the neighborhood of the ileo-cæcal valve. The circumstance that a single enema of tannin is sufficient to destroy the infection, leads Cantani to the conclusion that it not only acts as an astringent, but also as an acid, and gives to the contents of the colon an acid reaction and thus hinders further production of the cholera germs. After serious secondary changes have taken place the abortive treatment does not give favorable results. After the great loss of fluids and a consequent dry state of the tissues, hypodermic injections constitute the only hope for recovery. These must be resorted to before the heart-muscle has undergone change, the chemical composition of the nerve centres altered, and before the destruction of blood corpuscles renders successful treatment impossible.—*Centralbl. für klin. Med.*, Jan. 17, 1885.

AGARICINE IN THE NIGHT-SWEATS OF PHTHISIS.—M. SEIFERT has found agaricine to be useful in controlling the night-sweats of phthisis.

He employs it as follows:

Agaricine	gr. $\frac{1}{12}$
Dover's powder	gr. 100
Mucilage	gr. 60

Divided into 100 pills.

In almost every instance the effect is manifested after the administration of one pill, and two pills never fail to exert a beneficial influence. M. Seifert also alternates agaricine and atropia with good results.—*Journal de Médecine de Paris*, February 7, 1885.

FACIAL NEURALGIA TREATED BY NERVE VIBRATION.—DR. W. H. NEALE reports a case of facial neuralgia, in which marked improvement and probably cure resulted from treatment by nerve vibration. Drugs after long trial being found useless, the treatment under consideration was resorted to. All drugs being abandoned percussion was resorted to, and a small white ivory disk with about ninety vibrations to the second was used and applied to the spots at which most pain was felt. The pain at first was intensified, but gradually disappeared, and after a treatment of about three weeks the patient was entirely cured, and, at the end of four months still continues well.—*Practitioner*, November, 1884.

OIL OF GAULTHERIA IN RHEUMATISM.—DR. LEUBUSCHER has reported a long series of cases of rheumatism of the joints, in which he has used the oil of gaultheria with as good effect, in every instance, as heretofore was obtained with salicylate of soda. Humming in the ears and difficulty in hearing were also observed as concurrent effects.—*Wien. med. Presse*, Jan. 4, 1885.

SULPHATE OF COPPER IN OBSTETRICS.—DR. CHARPENTIER proposes to employ this salt in solution of 1 to 500 as an antiseptic of the first rank and which will be of signal service in obstetrics.

Its effect, he says, when used for vaginal or intra-uterine injection is entirely harmless. It has also valuable properties as a hæmostatic and astringent, and may be substituted for the perchloride of iron. The solution for this purpose should be of 1 to 100 heated to a temperature of from 96° F. to 100° F.

The injection should be continued eight or ten days, at intervals during each day, unless other effects than reduction of temperature and diminution of the pulse rate be observed.

In surgery it is valuable as an antiseptic, especially in extensive thrombus of the vulva, and in fetid abscess of the urethro-vaginal septum, even where solution of carbolic acid has failed to be of service.—*Journal de Médecine de Paris*, February 7, 1885.

TREATMENT OF EPILEPSY WITH OSMIC ACID.—WILDERMUTH, in the *Berlin. klin. Wochenschr.*, reports having used osmic acid in the treatment of epilepsy for two years. The remedy was administered internally, and also in the form of osmiate of potassium, in pills or bolus, each pill containing $\frac{1}{60}$ grain of potassium osmiate, and increased up to a quarter grain. The acid was previously given in a watery solution.

Trial was first made upon ten aged epileptics; seven showed no results; in two cases the attacks became less frequent; in one an extremely severe attack followed the administration in large doses. This was succeeded by decrease and diminution of the attacks and their final disappearance with improvement of the mental condition. Of three cases whose treatment with osmic acid is published, two show marked improvement both in diminished frequency and severity of the attacks, while in the third no results are yet noted. Unfavorable sequelæ have never been noticed.—*Allgemeine Wien. Med. Zeitung*, January 20, 1885.

THE PREATAXIC PERIOD OF SYPHILITIC TABES.—PROF. FOURNIER, after reviewing the different manifestations of syphilitic tabes previous to the appearance of ataxia, makes the following *résumé:* The ataxic period of syphilitic tabes covers a period which may vary between some months and thirty years. It is characterized by an invasion of isolated symptoms on the part of the organs of sense and the cerebro-spinal system and the genito-urinary apparatus. These symptoms frequently pass unnoticed, and it is only by careful observation that they can be appreciated. Recognition of them is very important as the only means of determining the preataxic period, and as offering the only time at which treatment with hope of cure can be instituted.—*Révue Médicale*, January 17, 1885.

THE MEDICAL NEWS.

A WEEKLY JOURNAL

OF MEDICAL SCIENCE.

COMMUNICATIONS are invited from all parts of the world. Original articles contributed exclusively to THE MEDICAL NEWS will be liberally paid for upon publication. When necessary to elucidate the text, illustrations will be furnished without cost to the author. Editor's Address, No. 1004 Walnut St., Philadelphia.

SUBSCRIPTION PRICE, INCLUDING POSTAGE,

PER ANNUM, IN ADVANCE, ... $5.00.
SINGLE COPIES, ... 10 CENTS.

Subscriptions may begin at any date. The safest mode of remittance is by bank check or postal money order, drawn to the order of the undersigned. When neither is accessible, remittances may be made, at the risk of the publishers, by forwarding in *registered* letters.

Address, LEA BROTHERS & CO.,
Nos. 706 & 708 SANSOM STREET,
PHILADELPHIA.

SATURDAY, MARCH 14, 1885.

ENTERECTOMY AND ENTERORRHAPHY.

IN the issue of THE MEDICAL NEWS for February 21st, we made some editorial comments upon a successful laparotomy and enterorrhaphy for gunshot wound of the small intestine, which called forth a letter from an esteemed correspondent, published in the issue of the following week, in which we are credited with favoring, positively and without qualification, the resection of the injured parts and uniting the ends with sutures, to the exclusion of the formation of an artificial anus. The correspondent further states that there is not an unanimity of opinion upon the proper practice to be pursued in operations upon the intestines; he quotes Whitehead and Reichel as being opposed to resecting, suturing, and returning the gut, and pays us the compliment of asking that we present the evidence and teaching upon this most important point of progressive surgery. As the subject is really one of great practical interest, it gives us pleasure to comply with his request, particularly as we feel that the desired information will be appreciated by other surgeons.

At the outset we must declare that we did not express an unqualified and positive opinion in regard to an exclusive method of treatment of shot wounds of the intestines. In the article in question, we distinctly stated that after an exploratory laparotomy, "if the gut be opened the wound can be closed with sutures, and hemorrhage arrested, thereby materially enhancing the chances of recovery. When the perforations are in close proximity to each other, the affected portion of the gut should be excised, the divided ends be approximated, and the coil be returned into the belly. The formation of an artificial anus, as attempted by Lloyd, is not desirable."

The opinion as to suturing, with enterectomy, in shot injuries was based solely upon experiments upon animals, not a single example having, so far as we know, occurred in the human subject. In the experiments of Parkes upon dogs, which may be found in THE MEDICAL NEWS for May 17, 1884, there are several illustrations showing, first, most extensive and severe lacerations produced by bullets of small calibre, the entire circumference of the bowel being at some points entirely destroyed; and, secondly, multiple perforations so closely situated that only half an inch or less of the wall of the intestine separates them from each other. In all such cases the extensive laceration can only be treated by excision of the damaged part, if the wound be single, or by excision of a coil of the intestine when the wounds occur close together. Ordinary suturing under such circumstances will not answer, first because of the constriction of the gut which would ensue; and, secondly, because the wall of the gut would be liable to slough. Hence, in cases of multiple perforations occurring close together, Parkes successfully removed in several instances ten inches or more of the intestine, while, when the openings were widely separated, and much damage done at each point, several resections, just sufficient to include the injured portions, were made. The practice of Parkes, we take it, is eminently proper, and the rule of excision should be absolute if the mesenteric artery supplying the injured area be divided, since the gut will become gangrenous, as has happened in at least five cases of pylorectomy, in which death was due to mortification of the transverse colon from the cutting off of its arterial supply. In simple, uncomplicated wounds, on the other hand, the case of Bull shows that suturing alone will suffice.

In the letter of our correspondent it is stated that Reichel has collected 121 cases of resection of the intestines, the conclusion being that the two ends of the bowel should not be united at the time of resection, but that an artificial anus should be established. On referring to the original paper, contained in the *Deutsche Zeitschrift für Chirurgie*, Bd. xix., 1883, we find that the conclusion is based upon the very proper assertion that sutures should only be used upon sound intestine, and that as the coats of the bowel are diseased or softened in strangulated hernia, intestinal obstruction and tumors, resection and suturing are contraindicated. The management of shot wounds is not even referred to.

In THE MEDICAL NEWS for February 2 and March 15, 1884, we directed attention to enterectomy with enterorrhaphy for artificial anus and for gangrenous hernia. Since those dates, we have added other cases to our lists, and are now able to confirm the statements made in those articles. Of 85 operations for gangrenous hernia, 51, or 60 per cent., died,

while of 65 for artificial anus, 22, or 33.84, succumbed. These facts indicate, as pointed out by Reichel, that the damaged condition of the gut in the immediate vicinity of the mortified portion is the chief cause of the greater mortality of the former operation, through the giving away of the stitches and the consequent fecal effusion. Hence, Reichel suggests that before resection be practised the gut be drained and kept moistened with an antiseptic agent until its normal condition in the vicinity of the gangrenous part is restored. Whether this course be pursued or not, the success of the operation will greatly depend upon cutting through and suturing sound tissues, even at the expense of removing a large amount of the canal, which appears to be a matter of no moment. Even with this large mortality—nearly 60 per cent.—circular resection and suturing of the gut in gangrenous hernia is less lethal than the establishment of an artificial anus for the same condition, the mortality of which is placed at 80 per cent. by Benno Schmidt, and at 86 per cent. by Ill. In favor of the former operation, it is, moreover, to be said that, if successful, the recovery is absolute, and that a secondary operation for the relief of an artificial anus is dispensed with.

In the operations that have been practised for the relief of carcinoma of the large intestine, resection with suture also shows a lower death-rate than the establishment of an artificial anus. Thus, the cæcum and the ascending, transverse, and descending colon, and the sigmoid flexure have been excised and stitched in at least 18 instances, with 8 deaths, or a mortality of 44.44 per cent., the operators having been Billroth in 3 cases, Kraussold, Czerny, and Schede, each in 2 cases, and Reybard, Gussenbauer, Baum, Fischer, Credé, Thiersch, Treves, Rehn, and Sydney Jones, each in 1 case. In only one, that of Baum, was the fatal issue due to the sutures, only six, instead of about thirty, having been inserted, and death having occurred from fecal extravasation. In all the others, the patients died of shock, and the sutures were properly applied. How well they do their work is shown by the case of Treves, in which, on death in twelve hours, there was no leakage, although the colon at the site of the sutures was distended with fluid feces.

Colectomy, or cæcectomy, with the establishment of an artificial anus, on the other hand, has been done by Billroth in 2 cases, and by Volkmann, Bryant, Marshall, Martini, Maydl, Lammiman, and Whitehead, each in 1 case. Of the 9 cases, 5 or 55.55 per cent., died, the mortality being greater by 11.11 per cent. than for resection and suture, and this despite the fact that the belly was opened in the former cases and the loin in the latter.

These data, together with severe test of the efficacy of excision and suturing afforded by pylorectomy, show that the conclusion of Reichel is not sustained, and that, with the evidence before us, the operation of excision, with suture of the divided ends, and return of the bowel into the abdomen, is safer than the formation of an artificial anus in cases of strangulated gangrenous hernia and in examples of obstruction of the large bowel by carcinoma.

We regret that want of space compels us to refrain from entering into a description of the technical details of the operation, but we may refer our readers to papers on the subject by Treves, in the *Medico-Chirurgical Transactions*, vol. 66; by Marshall, in the *Lancet* for May 13, 1882; by Reichel in the *Deutsche Zeitschrift für Chirurgie*, Bd. 19; by Bouilly and Assaky, in the *Revue de Chirurgie*, Nos. 5 and 7, 1883; The Medical News for March 15, 1884, and by various authors in the *Verhandlungen der Deutschen Gesellschaft für Chirurgie* for 1882 and 1883.

DEATH OF THE FŒTUS FROM DELAY IN DELIVERY OF THE BODY.

Dr. Schultz contributes to the February number of the *American Practitioner* an instance of death of the fœtus from the delayed expulsion of the body caused by uterine inertia. The case reported is not an anomalous one; indeed, it is not improbable that this accident, though by no means frequent, is, on the other hand, not very rare, and that there are but few obstetricians who have not met with a greater or less number of cases of difficult delivery of the shoulders. They, indeed, are very fortunate who have never seen a death from the delay incident to it. The treatment of these cases is then a most important practical question. In its discussion we shall lay aside those examples of great disproportion between the fœtal body and the birth canal, as, for example, when tumors of the fœtus, or ascites, delay or prevent the expulsion of the body.

The history of the cases in which a failure of uterine force results in retention of the shoulders after the head is born, is in some instances that of a protracted labor, the uterus having become exhausted by long efforts, and almost entirely ceasing to act after expelling the head. In other cases, the head has been delivered by forceps, because of failure of uterine action; and in many such, failure has been brought about by the too free administration of an anæsthetic, this agent having been given to the extent of abolition not only of sensibility, but also of volition, and almost of uterine contractions, which at least have become feebler and less frequent. Indeed we believe that many a child's life has been lost by the unrestrained use of chloroform or of ether in labor.

The danger to the child arises from compression of the chest, or from pressure on the cord, which may

encircle the body once or oftener, and thus render it more liable to have its circulation arrested.

To understand how we are to relieve the child most quickly and safely from its imminent peril, we must recognize the mechanism of labor in the delivery of the shoulders, for after this no delay usually occurs in the expulsion of the body. The passive movement of the fœtus in the mechanism of labor after delivery of the head, is rotation of the shoulders from the pelvic transverse to the pelvic antero-posterior diameter. The uterine contractions, the most important and active factor in causing such rotation, being weak or absent, we substitute for the *vis a tergo*, a *vis a fronte;* that is, with our hands we draw the fœtal head farther out, assisting, it may be, by suprapubic pressure, the descent of the shoulders, and we may also endeavor directly in this traction to turn the occiput toward the mother's left or right thigh, according as the occiput was originally toward the left or right side of the mother's pelvis; but traction and pressure being well made, we may generally trust this turning to nature. This movement having been effected, the anterior shoulder will be found just emerging at the pubic arch, for we hold that in all cases of perfect perineum the anterior shoulder, notwithstanding the conflicting statements of some obstetric authorities, is born first. This shoulder, as well stated by Pajot, represents the occiput in delivery of the head, and as in the latter delivery the nape of the neck or the suboccipital region becomes the fixed point resting upon the pubic arch, so the part of the arm just below the shoulder rests upon the arch until the posterior shoulder and arm are delivered, while the body undergoes lateral incurvation, a movement corresponding to extension in the delivery of the head.

Once the anterior shoulder has taken the position mentioned, our efforts must be directed to the delivery of the posterior shoulder, and this end we seek to accomplish by raising the head and making slight traction in order to bring the posterior shoulder far enough down so that a finger can be introduced into the axilla and traction thus made. But if we fail thus to reach the axilla, we may, as advised by Spiegelberg, and as taught by the late Professor Hodge, push the anterior shoulder in behind the pubic joint, thus bringing the neck of the child in the pubic arch, and causing it to press against the subpubic ligament, and by this means the posterior shoulder can usually be brought to the margin of the perineum. This having been accomplished, the head is carried backward, when the anterior shoulder again comes just outside of the pubic arch, and delivery is easily effected.

In some cases a blunt hook placed in the axilla may be necessary, only one must be careful, as advised by Spiegelberg, not to act upon the humerus on account of the risk of detaching the epiphysis.

Jacquemier taught that after the head is born two methods are offered: the one, traction upon the head, —it sometimes succeeds, but often fails; the other, traction by the fingers in the axilla. He looked upon the latter proceeding as only preliminary to the disengagement of the arms, drawing upon which the trunk is delivered. He thought this method not only furnished the best means of exerting traction, but also very advantageous by lessening the size of the chest. Charpentier endorses the practice, but frankly states the occurrence of an accident in a case in which he pursued it—fracture of the humerus. He also mentions that traction by the finger in the axilla caused paralysis of the opposite arm; the fracture was cured in nine days, the paralysis in four months. Spiegelberg, wisely, as we think, rejected bringing out the arms, on the ground of danger of fracture of the bones, or injury to the epiphyses, holding that if there was room for this manipulation, there was room for delivery without it by other methods. If the child be dead, the only question as to delivery is to use those means which will be safest and best for the mother.

THE DIFFERENCE BETWEEN THE FALSE MEMBRANE OF DIPHTHERITIC AND THAT OF CROUPOUS LARYNGITIS.

Prof. Virchow has recently taken occasion, before the Berlin Medical Society, to express himself pointedly upon the difference between the tracheal membrane found in croup, and the so-called false membrane in diphtheria of the fauces. The former is a true fibrinous membrane found on the surface of the trachea, and, under favorable circumstances, can be expectorated. The latter is something altogether different. It is a necrotic surface which gradually separates itself, not by a process of simple exfoliation, but by ulceration. Diphtheritic, unlike croupous membrane, can never be forcibly separated from the fauces without leaving a raw surface of greater or less depth. Moreover, cases of diphtheritic bronchitis extending even into the parenchyma of the lung have been observed, in which the false membrane consisted of a necrotic layer penetrating the tissues to a varying depth, instead of the usual croupous process attended by the presence of the superficial easily separable false membrane.

As to the question of infection, Virchow held that while we have not yet been able to cultivate the parasite of diphtheria, it is true that the diphtheritic focus, let it be as small as it will, is full of small granules, which he does not hesitate to regard as parasitic organisms although he formerly regarded them as exudation granules. Certainly they can be very easily inoculated. To prove this one has only

to introduce them upon the surface of the mucous membrane, or on a wound in it, when there promptly succeeds a process in which similar granules are invariably present, just as is the case with other forms of parasitic inoculation. These granules are entirely wanting in the true croupous membrane.

For these reasons he considers the two to be totally different processes. He believes, however, that the diphtheritic process, if quite superficial, may also be accompanied by a fibrinous exudation, but not when deep-seated, because the bloodvessels of the mucous membrane are entirely occluded so that circulation, and therefore exudation, is impossible.

When the diphtheria, therefore, is superficial, the two processes are identical, so far as the formation of false membrane is concerned, but the moment the diphtheria is deeper they again differ, because the exudation ceases. Virchow further believes that the granules in the necrotic or diphtheritic membranes are probably insoluble in digestive and other fluids, while the fibrinous exudate is. Practically, however, this fact avails us little, because in the pharynx, where they could be reached, the true fibrinous membranes are least likely to occur, and in the trachea they are too remote to be influenced by available solutions.

GENERAL GRANT'S ILLNESS.

SINCE our report of last week, GENERAL GRANT'S condition, we regret to record, remains unimproved, and we find nothing in the history of the progress of the case upon which to base a hopeful prognosis. The ulceration in the right anterior pillar of the fauces, we are authoritatively informed, has progressed, and the mucous membrane of the hard palate is invaded by the induration, which varies from day to day, being sometimes less and sometimes greater. The induration of the tongue has undergone but little, if any, ulceration. The glandular enlargement, on the right side of the neck, is about one and one-half inches in its longest diameter, and has increased but little, if at all, in size since it was first observed in the autumn.

The diagnosis of the affection from which the General suffers, rests between epithelioma, lupus, and scrofulous or tubercular ulcer, specific infection being entirely out of the question. We think, however, that this expression of a doubt arises rather from reluctance to abandon all hope than from any actual uncertainty as regards the epitheliomatous character of the disease.

The only changes which the disease has undergone during the past week are the slight increase of the area of ulceration in the anterior pillar of the right fauces. The General has suffered from loss of sleep; and his nights have been bad, although there has not been much pain. The question of operative interference is not considered, but it may be deemed advisable to divide the lingual nerve for the relief of pain, in case it becomes a prominent symptom.

THE QUESTION OF VIVISECTION.

ANTIVIVISECTION literature grows apace. As the antivivisectionists do not think and reason, but only feel and declaim, as they are happily oblivious of facts, and mistake a vague sentimentality for scientific knowledge, the only limit to their productive activity is the boundary imposed by the credulity of their followers. The medical members of this cofraternity of hysterical enthusiasts and humanitarian sentiment drivers seem to be actuated by two designs: the desire to enjoy the sensation of a personal goodness superior to that of their benighted medical brethren; the attempt to pose before the public as reformers with a lofty mission.

The latest production of this sentimental school has recently been published in this city, and is entitled "The Question of Vivisection. Was the Act of the British Parliament in Restricting Vivisection Inconsiderate and Unnecessary?" It is not only characterized by monumental ignorance of the "question," but it misrepresents, in the most barefaced manner, the opinions of well-known authorities. That this severe judgment is justified, is fully confirmed by a comparison of the author's statements with the published record. Thus on page 8 of this remarkable pamphlet, we find the following sentence:

"Neither can this cause any surprise when an Owen, a Ferguson, a Ferriar [Ferrier], a Darwin, a Bernard, and others, having similar experience, have been frank and independent enough to confess the inadequacy of experiments upon living animals to establish a reliable diagnosis, and, as a sequence, a reliable therapeutical treatment of disease. In this view, the preëminent experimentator, Virchow, concurs," etc.

This blundering attempt to make Bernard an opponent of vivisection is simply ludicrous. If its author, or any of our readers, will consult Bernard's *Introduction a l'étude de la Médecine Expérimentale*, Paris, 1865, p. 218, he will read that, of which the following is a literal translation:

"Experiments on the higher animals in our day throw light on the questions of special physiology and pathology, which are applicable to practice—that is to say, to hygiene or to medicine. . . . The experiments on animals with deleterious or noxious substances are very useful and perfectly conclusive for the toxicology and hygiene of man. The researches on medicaments or toxic agents are equally applicable to man, from the therapeutic point of view; for, as I have shown, the effects of these sub-

stances are the same in animals as in man, except the difference in degree."

Who, besides the author of this pamphlet, does not know that Ferrier's title to fame rests on his experimental work in animals, done to establish cerebral localizations? Do we not all rely on this work to fix the site of cerebral lesions, and was it not utilized but the other day to determine the situation of an intracranial growth removed by the trephine and knife of the surgeon guided by the same information? Is it not equally absurd to quote Virchow in the same breath, when the ink has scarcely dried on his elaborate paper defending the practice of vivisection?

The antivivisectionists should seriously ponder the weighty words of Mr. Matthew Arnold on "clear thinking and straight seeing." They should learn to appreciate this fundamental truth—that it must be quite as meritorious to employ animals to improve the mind as to nourish the body, or do they believe that man's intellectual powers are of less importance than his somatic functions? We doubt if they impugn the humanity of the butcher, unless the matutinal steak proves to be tough to the teeth and unsatisfying to the stomach.

SOCIETY PROCEEDINGS.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, March 5, 1885.

The President, A. Jacobi, M.D., in the Chair.

Dr. William C. Jarvis read a paper on

THE ETIOLOGY AND TREATMENT OF NASAL CATARRH, WITH SPECIAL REFERENCE TO THE DEVIATED SEPTUM; WITH PRESENTATION OF INSTRUMENTS.

The impression, he said, had become quite prevalent among the public, and to a certain extent in the profession, that chronic nasal catarrh was incurable. Such was by no means the case, however, when the affection was treated in a rational manner, which involved the discovery and removal of the cause giving rise to it. In a paper on hypertrophic nasal catarrh, which he read before the American Laryngological Association in 1880, he had referred to deviated septum as a very prominent factor in the etiology, and described a treatment by novel methods. His subsequent experience had only confirmed him in his conviction of the very great importance of this factor. As to the character of the abnormal condition of the septum, it might be osseous, cartilaginous, osteo-cartilaginous, and hypertrophic. In situation, the deviation might be localized or general throughout the septum. The purely osseous form was rarely met with, being almost invariably associated with the cartilaginous. The cartilaginous was by far the most common of all.

The factors concerned in the production of deviated septum were, first, pressure-irritation; and, second, defective nasal drainage. Of the effects of pressure, he had spoken particularly in the paper referred to. Although the turbinates might not be found pressing upon the tissue over the septum, the existence of this form of hypertrophy afforded, he thought, clear proof of contact at some period of the disease; a certain amount of turbinated hypertrophy was always found in connection with it. He had a drawing taken from a patient, the right side of whose vomer was occupied by a cup-shaped hypertrophy, the depression on its surface being the impress of the inferior turbinate lying opposite. The inferior turbinate bone of the other side was enlarged and pressed against the vomer, the tissue over which had already commenced to thicken.

In speaking of the matter of defective nasal drainage, Dr. Jarvis described the peculiar anatomical formation of the parts below the nose, which gave them their adaptation to drainage. Thus the palatine prominence divided the passage into two gutters to conduct the mucus when it left the cavity of the nostrils, while the discharge was prevented from entering the larynx by the slight elevation made by the arytenoid cartilages, the cartilages of Wrisberg, and the folds of mucous membrane. The importance of this system of nasal drainage, he said, was very clear, and any disturbance of its balance would certainly give rise to trouble. Prominent among such disturbances was deviated septum.

Among the causes of the latter, he mentioned heredity and traumatism. Deviated septum might also be acquired. In regard to the first cause, he said that malformation of the hard palate was often transmitted from parent to child, and that it was not infrequently associated with deviation of the septum. No two palatine arches were exactly alike, but while there might be considerable variation without positive abnormity, the formation of the part in which there was an abrupt elevation along the line of the median raphé was the one which caused difficulty, because it was almost necessarily combined with a corresponding deviation of the septum, giving rise to chronic rhinitis. He then referred to a number of instances in which he had observed this malformation of the hard palate in several members of the same family, all of whom were the subjects of old catarrhal trouble. As a result of his observations, therefore, he dissented from the hypothesis that there was a constitutional diathesis which transmitted nasal catarrh. He had found that remarkable mental capacity was apt to be associated with chronic nasal catarrh, because a large cranial vault was not infrequently attended with unusually contracted nares. Early acquired catarrh, therefore, instead of being of scrofulous or diluted syphilitic origin, was likely to be due indirectly to unusual cranial development.

Traumatic deviation of the septum was most frequently met with among the lower classes of society, and he said he had yet to meet with the first professional sparrer or prize-fighter, however healthy he might be in other respects, who was not the subject of chronic nasal catarrh.

Acquired or induced deviated septum was the result of prolonged intranasal pressure from hypertrophied tissue, polypi and other tumors, the repeated introduction of the finger, etc.

Passing on to speak of the treatment of deviated septum, he said that no single method was suited to all

cases. To cure the catarrh dependent on it, it was necessary to remove the deviation. His ring-drop speculum was of service in dilating the nostril. The instrument which he most used for removing tissue was the écraseur, which he had described on previous occasions. The piano-wire which he now employed with it was of a very fine size. Combined with the écraseur, it was invariably required to use his transfixion needles, which were from one to four inches in length, straight and of various degrees of curvature. In order to economize time in certain cases, he had devised other instruments, such as his fenestrated cartilage forceps and beaked scissors, which were bent at the proper nasal angle for operating and observing. As bone blunted their keen edges, when osseous tissue was to be cut through he employed the *rongeur* forceps, which removed it by a kind of biting process. When the deviation was extreme, there was considerable danger of perforating the septum, and on this account he preferred the stellate punch in such cases.

The cutting was usually the simplest part of the operation; the great difficulty being the proper approximation and adjustment of the fragments. Ordinarily the pain produced by the écraseur was not great, but he had found cocaine of the greatest possible service, as a rule, in relieving it. He was in the habit of using Farcard's ten per cent. solution. In any case in which the pain was extreme, however, there was nothing so good for producing local anæsthesia as rhigoline, applied with a spray; pain being an absolute impossibility when this was employed. The objection to the use of rhigoline is its liability to explode when its vapor comes in contact with the light used to illuminate the nasal cavity. This, however, had now been obviated by an electric light, enclosed in a glass bulb, which he had devised, and which he now exhibited. It was maintained by the Foster battery, which was in reality a combined battery and accumulator. It was especially valuable on account of the long continuation of the current, and its inventor, Mr. Foster, claimed that it was not necessary to refill it more than once a year. In conclusion, Dr. Jarvis exhibited his rhinometer or nose measurer.

Dr. Francke H. Bosworth said that he must take issue with Dr. Jarvis on some points. He thought that it was about time to drop the use of the word "catarrh," which meant simply a discharge, but was made to cover the whole area of nasal diseases. The catarrh was merely a result of these various diseases. As to pressure-irritation in connection with deviated septum, in the number of the *American Journal of the Medical Sciences* for January, 1876, Dr. Harrison Allen had published a paper which excited a great deal of controversy, in which he concluded that two mucous surfaces coming into contact with each other give rise to the results claimed by Dr. Jarvis. For his own part, he did not believe that this pressure was the cause of trouble, and there were numerous instances that could be observed in which two mucous surfaces come in contact with each other without producing evil results. Pressure irritation, he was convinced, was of no weight in this connection until very late in nasal disease. As to the matter of defective nasal drainage, the nasal fluid was about as benign and unirritating a one as could well be imagined, and the cause assigned by Dr. Jarvis did not go down to the ultimate source of the truth. The points most dwelt upon in the paper, he thought, were merely adventitious features of deviated septum. In nine cases out of ten, in which this existed there was catarrh. The use of cocaine, as now resorted to for the last three months, enabled us to eliminate swollen mucous membrane by its local effect on the parts, and permitted us to make a thorough examination of the exact condition present. He believed that a primary factor in the etiology was an interference with the normal respiratory function in the nose; the rarefaction of the air in the nasal passages leading to dilatation of the neighboring venous sinuses. He did not himself believe in a diathesis causing nasal diseases; but, unfortunately, Dr. Jarvis in speaking of the matter of heredity, had referred to the ulceration of the palatine arch, which was well known to be one of the effects produced by *mollities ossium*. In this case there was undoubtedly struma, resulting in softening of the bone, and the nasal catarrh was one of the adventitious results of the struma. The indication in the treatment was to remove the obstruction occasioning the nasal stenosis, and, of course, a great variety of instruments and methods might be employed for this purpose. In performing these operations, he was constantly in the habit of using cocaine, and almost invariably with complete success in abolishing pain. On account of the great expense of the drug, he used only a two per cent. solution; but by applying it to the parts to be operated on for twelve or fifteen minutes before commencing, he found that it acted in a perfectly satisfactory manner.

Dr. S. O. Vanderpoel, Jr., referred to an article by Dr. Roberts, of Philadelphia, published in the *Boston Medical and Surgical Journal*, in which he described an operation for deviated septum consisting of division of the septum with a bistoury, and subsequent retraction of the parts by means of a pin introduced through the concave nostril. He had himself now employed it with very fair success in four cases. In a fifth (that of a small child) the pin was inadvertently pulled out by the attendant. In one of the cases the nostril was so occluded that he found it necessary to employ Adam's forceps to break up the septum before resorting to the pin. The pin, he thought, possessed a great advantage in the fact that when it was used it was not necessary to have any large foreign body in the nares, such as the usual nasal splints.

Dr. D. Bryon Delavan said that he would have to take exception to the treatment advocated by Dr. Jarvis. He believed that deflection of the septum was due to a deviation of osseous structures, and many skulls that he had examined showed an extreme degree of deflection of the septum. But there are other changes involved, such as enlargement of the turbinated bone and the arch of the nose where the cavity was the wider; and he had observed that patients with deviated septum often breathed better through the narrower nostril than through the wider one. The bony structures thus being involved, it was not enough to remove merely the soft tissue, but it was also necessary to take away a portion of bone. It was impossible to replace a deviated septum when there was an enlarged turbinated bone on the narrow side. It seemed to him, therefore, that in many cases the method described by Dr. Jarvis was not equal to the exigencies of the situation.

Dr. Jarvis remarked that his paper had evoked less

hostile criticism than he had anticipated. He quite agreed with Dr. Bosworth that the name catarrh was objectionable; but, as he himself had said some time ago, he thought it well to employ it on account of its long continued and generally accepted use, though not attaching any pathological significance to it. Moreover, in the paper, instead of always speaking of chronic nasal catarrh, he had alluded to hypertrophic rhinitis as a frequent condition. As to the fact of pressure-irritation resulting from prolonged contact of the parts, he was fully convinced of its existence and importance, not only from pathological researches, but from the physiological action of the turbinated bone which he had repeatedly observed in the living subject. He quite agreed with Dr. Bosworth that normal mucus was not irritating; but thickened mucus of an increased specific gravity would invariably cause irritation by toppling into the larynx and closing up the nostrils. In regard to the production of local anæsthesia, if cocaine was too expensive, rhigoline would prove perfectly satisfactory, and that could be purchased for sixty cents a pound. If the electric light described could not conveniently be obtained, operations could be done in strong sunlight, although, as a rule, artificial light was preferable. He believed that the osseous turbinated enlargement referred to by Dr. Delavan did occasionally occur; but it was the rare exception, not the rule, and he had personally seen only two instances of it. If the condition existed, the methods he had mentioned (particularly the use of the *ronguer* forceps) would be found sufficient for the purpose of removal. As to the association of mental capacity with chronic catarrh, he thought that enlargement of the cranial dome was apt to be combined with contracted bones of the face and a high-arched hard palate.

Dr. George G. Hopkins, of Brooklyn, reported

A CASE OF FIBROMA OF THE BREAST AT SEVEN AND ELEVEN YEARS.

The patient was a child eleven years of age, living in the West, who four years previously had had removed from the right mamma a hard tumor, by a physician who had since died. It was almost an inch in diameter, situated in the structure of the gland to the right and on a line with the nipple, and was pronounced to be of a malignant character. About six months after its removal (in 1881), a tumor of the left breast was first noticed, which continued to increase in size until 1883, when it was an inch in diameter. There was then apparently no further growth until last June, when it began to increase rapidly. Dr. Hopkins first saw the girl on the 1st of September, 1884, when he found that the glands of the axilla were already implicated. On the 6th of October, assisted by Dr. J. C. Hutchison, he removed the entire mamma, including the nipple and areola, and also four of the axillary glands. The operation was performed with antiseptic precautions, and the entire dressing was removed on the ninth day, when it was found that the wound had healed. Some of the catgut sutures employed had already dissolved, and the remaining ones were dissolved by the eleventh day, while the drainage opening closed up on the sixteenth day. Under the microscope the tumor showed the characteristic fibroid structure, and the interest of the case lay in the early appearance of the disease, as there could be little doubt that the tumor which had been removed from the right breast was identical in character. In his work on mammary tumors, Dr. S. W. Gross stated that fibroma might appear as early as the age of twelve. Six per cent. of the cases recorded by him were under sixteen. Personally he pronounced the present growth to be fibroma, and said that he had heard of no previous case as early as seven years. The amputated breast and microscopic specimens from the tumor were exhibited. Dr. Hopkins stated that the mother of the child was the subject of uterine fibroids.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

Stated Meeting, February 5, 1885.

The President, B. F. Baer, M.D., in the Chair.

CALCULI IN THE FEMALE.

Dr. J. W. Snowden exhibited the stones and related the history of the case. He was called, June 1, 1884, to see Mrs. L., aged 23 years. She was born and has resided in a limestone region in New York.

Up to 13 years of age she was troubled with enuresis; wetting the bed almost nightly. After this she ceased passing her urine during sleep, but was obliged to rise for this purpose two or three times during the night. She could not retain her urine night or day after the desire to pass it came on. If she could not reach a convenient place, she would wet her clothes.

She married when seventeen years old. Two months after marriage she began to have cystic irritation and soon passed sabulous matter and small calculi. These symptoms continuously increased. Physicians whom she consulted said she had catarrh of the bladder, but none made an examination for stone. Once she was obliged to have a calculus removed which had become impacted in the urethra.

Two years ago she spent a summer in New Jersey, during which time she passed no gravel, but the irritation of the bladder continued. When he first saw her she was urinating very frequently, with more or less pain. She passed stones daily, with a great deal of sabulous matter. The urine looked as if there was a quantity of ordinary sand in the bottom of the vessel. He proposed an examination for stone, which she refused, peremptorily. He gave her benzoic acid, which entirely stopped the passage of the sabulous matter and relieved her in every way, but she still occasionally passed a small calculus. This marked relief lasted two or three months, when the irritation of the bladder became worse than ever. She could only pass her urine in the erect position and with as much effort as a woman in labor. He insisted upon an examination for stone, but the slightest touch excited such intense pain even when she was well etherized, that being alone he could not manage her, and he sent for Dr. Baer in consultation.

A calculus measuring about one and a half inches in its longest diameter was found in the bladder and removed by Dr. Baer after rapid dilation of the urethra. This afforded marked relief and she soon seemed entirely cured; but in a short time her urine began to dribble continually while she was in the recumbent position at night. During the day she retained and

passed her urine naturally. He advised her to get up at stated intervals and empty her bladder, which has gradually relieved this trouble. She is now quite well except that she urinates rather more frequently than is natural.

NEW YORK SURGICAL SOCIETY.

Stated Meeting, February 24, 1885.

The President, Robert F. Weir, M.D., in the Chair.

FIBRO-MYXO-SARCOMA OF THE TENDONS OF THE WRIST.

The President presented a patient, married, eighteen years of age, who four years ago first noticed a tumor on the posterior surface of the left wrist. In 1882 she came under Dr. George A. Peters's care, who removed the tumor, and about three months afterwards, while the patient was yet in the hospital, he extirpated some cervical lymphatic glands which had undergone cheesy degeneration. The growth at that time was examined microscopically, and pronounced a myxo-sarcoma. It recurred within a year and a half, when the patient came, temporarily, under Dr. Weir's observation. Last fall she entered the New York Hospital. There was then a tumor lying over the wrist-joint, on the dorsal surface, about two inches in length, oblong in shape, and which had somewhat the feel of a compound ganglion. Pressure at the lower part of the tumor gave a sense of fluctuation, and at the upper portion the sensation of the presence of rice bodies could be detected to a slight extent. Dr. Weir resolved to extirpate the growth, and did so by making a long incision, and when he had reached the tumor he found that it was adherent closely to the tendons of the extensor communis digitorum, and dipped down into the tissues below, so that in removing it one of the tendons (the thumb's inner extensor) was divided and the wrist-joint opened. From the extent and general appearance a question arose as to its exact nature. It presented thickened tissue with a number of small growths from its inner surface, with a certain amoun of gelatinous fluid in its substance. No free rice bodies were found. From the gross appearance it was thought possible, since Koenig had shown that the tubercle bacillus may give rise to ganglionic formations, that this might be one of those varieties of tumor, and the growth was subsequently examined with reference to this particular point.

The interest of the case centred not only upon the rarity of the lesion—that is, sarcomatous disease of the tendons, but also upon the somewhat apparent conflict of opinion with reference to the nature of the tumor. Dr. Peabody, the pathologist of the hospital, who had examined both the first growth removed and the present one, reported that it was a myxo-sarcoma. Two other pathologists had examined the tumor and reported that they found only granulation tissue. Dr. Hall, who had been much interested in surgical diseases of tubercular origin, had taken special pains in the examination of the neoplasm, and had presented the following report:

Gross appearance is that of gray gelatinous granulation tissue, closely resembling so-called fungoid granulations. A microscopic examination shows large bundles of white fibrous tissue, wavy, and containing large spindle cells. The bundles cross each other in different directions, so that some are cut across transversely, some longitudinally, and some obliquely. Between these are masses of tissue consisting of small round and spindle cells, with abundant granular intercellular substance. Here and there throughout the section are small masses of adipose tissue. The tissue is moderately vascular, some of the vessels having well developed walls, and others having very thin or no true wall, resembling those usually found in sarcoma. Diagnosis: fibro-sarcoma.

October 8, 1884, inoculated two guinea-pigs with the fresh material in the left inguinal region, subcutaneously. A similar wound, without inoculation, was made just previously on a third guinea-pig, for control. All wounds were closed with catgut stutures, and healed per primam. January 2, 1885, one of the inoculated guinea-pigs found dead in box. On examination body well nourished, lymphatic glands not enlarged. No trace of tubercle in the internal organs or elsewhere. The other two guinea-pigs are well nourished, and show no glandular enlargements.

The patient herself shows no recurrence of the growth, and has full use of her hand. The function of the thumb is also perfect.

Dr. G. A. Peters remarked that the tumor which he extirpated was connected with the sheath of the tendon, and presented the appearances described by Dr. Weir.

Dr. T. M. Markoe then read a paper on

SECONDARY NERVE SUTURE.

(See page 285.)

Dr. Briddon referred to a paper which he read before the Society two years ago, and in which he reported a case of secondary suture of the ulnar nerve, performed several months after the injury, which was produced by the patient falling and striking upon a broken glass tumbler. At the operation a small piece of glass was found between the severed ends of the nerve, and the proximal end was bulbous. No benefit whatever was derived from the operation. The man died a year afterwards from phthisis, and at the time of his death there had been no return of either sensibility or motion. He was unable to obtain an autopsy.

Dr. L. A. Stimson thought that the long-delayed return of function was a point to be borne in mind constantly. In one of his own cases, injury of the musculospiral nerve was followed by complete motor paralysis which lasted for more than three years, and then was succeeded by complete recovery of function by the muscles supplied by this nerve.

Dr. Markoe thought that the question of the possibility of natural restoration should be always borne in mind, and it is quite possible that many cases operated upon would have recovered after a long period. It was this fact which induced him to wait until one hundred and thirty days in one of his cases before operating. There were not, so far as he was aware, any statistical statements of the results of section of nerves in which no operation was performed.

Dr. Poore asked with regard to the longest time that had elapsed after an injury in which an operation had been performed with any success.

Dr. Markoe replied that in Dr. Weir's case the operation was performed nine years after the injury, and in another case the operation was performed six years after the injury. Certain it was that some of these sections produced paralysis which was permanent. How we were to ascertain whether any given section would terminate in recovery or not, he was unable to say; and he thought, therefore, that, granting the possibility that the nerve might recover its power, the operation should be performed after waiting a reasonable length of time to see what nature could accomplish.

Dr. Poore remarked that about one year ago he saw a child eight years of age who, five years previously, sustained a fracture of the head of the radius, and the bone had united at an angle. At the time of the injury pulsation of the radial was lost, which was shortly followed by ulceration of the hand and arm, accompanied with total paralysis of the extensors, which has persisted, and at time of examination the muscles on dorsal surface of forearm were atrophied.

Dr. G. A. Peters asked if additional damage had been done in any cases by the operation.

Dr. Markoe replied that no further impairment of function had resulted from the operation, and in no instance had death occurred as a result of the operation.

The President called attention to two points in the technique of the operation. In his case he found great difficulty in overcoming the gap between the divided ends of the sciatic nerve which, after they had been trimmed off, were separated to the distance of two and a half inches, and which could only be overcome by liberating the nerve to a considerable extent and strongly flexing the limb; but, in addition to the sutures applied to the nerve itself, extraneous sutures in the soft parts outside were used, and were especially serviceable.

From the difficulty in approximating the ends of the nerve in that case, he was all the more disposed to resort to a suggestion that had been made, namely, to make a bayonet section in one of the nerves, splitting the nerve not quite to its free extremity, and turning it over and thus effecting the desired elongation. This has since been tried, and had been found to require the additional precaution in its employment, that when the nerve was so stretched a suture should be inserted into the free end to prevent it from tearing completely through.

CHOPART'S OPERATION.

Dr. L. A. Stimson presented a cast of a stump left by a medio-tarsal amputation, together with the dissected member. They were taken from a cadaver found in the dissecting-room. There is no history, but the stump was evidently an old one. The body was that of a man 50 or 60 years old. The cicatrix is horizontal, and fully half an inch above the line of pressure in walking. The face of the stump was covered with a thick, well-padded layer formed of the flesh of the sole; had a thick layer of epidermis; and showed no signs of present or previous ulceration. On dissection, the tibialis anticus was found much more wasted than the other anterior muscles, and its tendon was reduced to a small end adherent to the soft parts of the upper flap. The other anterior tendons were adherent to the cicatrix. The head was drawn upward, so that the anterior face of the os calcis was directed downward and forward, lying in a plane inclined about midway between the vertical and horizontal planes when the limb was erect. The astragalus showed a corresponding degree of plantar flexion, and the range of motion in the ankle-joint was about 10°. Its scaphoid articular surface was firmly attached to the flap. There was a small osteophyte on the upper outer anterior border of the os calcis. The stump appears to have been a thoroughly useful one, notwithstanding the well-marked plantar flexion.

Dr. Markoe remarked that the specimen illustrated in a striking manner one of the objections which had been urged against the operation, namely, change in the position of the heel.

Dr. Sands said that the cicatrix did not seem to have been presented to the ground.

Dr. Stimson remarked that the point of pressure was well protected.

Dr. Sands asked if the specimen did not rather refute than sustain the objection urged against Chopart's operation by showing that the retraction had not been such as to cause the cicatrix to come into contact with the ground in walking.

Dr. McBurney remarked that some time ago he presented to the Society a patient upon whom he had performed Chopart's operation, and the result did not exhibit any of the defects said necessarily to accompany the operation; that is to say, the patient had complete control over the bones of the foot left, and was able both to flex and extend the stump. He could also present the original plantar aspect of the foot to the ground. At that time he made a statement, which he still felt like adhering to, namely, that the greatest importance was to be attached to the manner of treating the stump immediately after the operation, and not to allow the limb to rest with the muscles at the back of the leg having entire control. The stump should be firmly flexed throughout the healing process, so that the anterior tendons will become attached as low down as possible.

Dr. C. A. Peters asked how the flexion was secured.

Dr. McBurney replied that it was secured by the application of a posterior splint, the part presented to the sole of the foot turned upward to the ankle and fixed it in that position. The immediate splint was made of pasteboard, and secured with plaster of Paris. Even upon the dead subject, when Chopart's operation was performed, if the limb was held free there would be a noticeable dropping of the os calcis, with a bending downward of the anterior portion of the stump.

Dr. Markoe remarked that he understood that the objection to the operation was not because the original stump presented a badly situated cicatrix, but that by the contraction of the gastrocnemius, and also from the irregular face of the os calcis, it was gradually pushed back and came finally to press upon the ground in an unfavorable position.

Dr. McBurney said that Dr. Sabine, in one of his recent visits to the West India Islands, found that the operation was performed in that locality very frequently for the relief of certain diseases which affected the toes of negroes, necessitating amputation of the anterior part of the foot. He was told by local surgeons that the results were good, and that they had never seen twisting of the os calcis upon itself. The patient whom he pre-

sented to the Society could run upon his stump, and he had never had any artificial support.

DR. STIMSON called attention to the fact that the preservation of motion of the ankle-joint diminishes the friction of the face of the stump against the ground in walking.

HYDATIDS OF THE LIVER AND MESENTERY; LAPAROTOMY.

THE PRESIDENT presented a specimen accompanied by the following history:

Richard H., a native of England, twenty-six years of age, resident of New Jersey, was admitted to the New York Hospital January 21, 1885. The patient's personal history is negative. There was no special history with regard to diet, although he preferred rare meat to that which was well cooked. In June last he first noticed that his abdomen was beginning to increase in size, and the fulness was first noticed over the region of the liver. There was no pain in the enlargement, and it inconvenienced him only on account of its weight and dragging. Whether the patient had had more than the ordinary association with animals, dogs and sheep, said to be infested with the parasite which gave rise to hydatids, Dr. Weir was unable to make out.

At the time of admission the patient was a rather thin but healthy looking man, weighing one hundred and fifty-eight pounds. His abdomen and lower part of the thorax were much distended. The circumference of the abdomen at the umbilicus was thirty-six and a half inches; at the lower border of the ribs thirty-nine inches. The right lower ribs bulged outwards very much more than the left. On palpation a large tumor, the size of a man's head, was felt in the right upper part of the abdomen, and another, nearly as large, occupying the lower part of the abdomen, and between these tumors another, about the size of an egg, could be distinctly felt, which was freely movable over an area of several inches. The large tumors extended over beyond the median line toward the left side for several inches. On palpation a sensation of fluctuation could be detected, but it did not apparently communicate from one tumor to the other. No hydatid fremitus detected. A hypodermic needle was introduced and perfectly clear fluid withdrawn, which was negative by microscopic examination. Examination of the urine was negative. Diagnosis of cystic tumor of the abdominal cavity, probably hydatid, and probably involving the liver. Whether the tumors were independent or united was a matter of some doubt.

The question arose mainly with reference to the treatment; that is, whether puncture or incision should be made. After considering the matter, Dr. Weir resolved to resort to incision, and on the 24th of January he made an opening through the abdominal wall two inches and a half in length in the epigastric region, and when the tumor was reached it showed itself as a thickened white mass. The peritoneum was first secured to the edges of the abdominal wound by sutures all round, and then a large-sized trocar was plunged into the cyst, but only a few drops of clear fluid escaped. Had he succeeded in obtaining fluid with the trocar, he had intended to draw the tumor up as high as possible, open it freely, evacuate its contents, and sew its walls to the peritoneal surface of the abdominal wound. After the canula was removed the edges of the opening were seized with the forceps and lifted up out of the incision, and the opening in the cyst was then enlarged to the size of the abdominal wound. Hundreds of amber-colored and transparent cysts escaped, varying in size from a pea to an orange. The quantity was not noted, as considerable escaped so that it could not be measured, but the entire quantity was estimated at from four to five quarts. The edges of the sac were then sutured to the external wound, and two large-sized rubber drainage-tubes inserted. Peat dressing was applied. The operation was begun with full antiseptic precautions, but had not proceeded far before the steam atomizer gave out, and it was continued without the further use of spray.

Jan. 25th, the patient complains of much pain in the head, and requires to be catheterized. January 25th, pain in the head continues, but the patient passes his urine. No peritonitis. Temperature rose this afternoon to 103.4°. The wound discharges hydatid cysts. Dressings are changed under spray when necessary. January 27th, urine contains about ten per cent. albumen. The wound was dressed under the spray, and more hydatid cysts were discharged. On the third day there was suppression of urine with elevation of temperature, and from this time the case progressed unfavorably, and the patient died ten days after the operation. On the eighth day after the operation the cyst cavity was washed out thoroughly with a bichloride solution, 1 to 5000. At that time it was discovered that the lower tumor was diminished in size. Until this time it had been considered a separate tumor.

The autopsy showed that the tumor was a large bilobed formation with a separate tumor which was in the mesentery, and that in the walls of this large mass, which had invaded completely the substance of the right lobe of the liver, quite a large number of hydatid cysts were found projecting into the abdominal cavity, so that if the patient had recovered it would have been only temporary. The liver was forced downward so that its upper surface looked forward and was adherent to the under surface of the diaphragm, and to the upper surface of the diaphragm the lower lobe of the right lung was adherent, a fact which pointed somewhat toward an effort of nature to effect evacuation of the tumor in this direction.

There were two points in the operation which Dr. Weir regretted not having observed. First, in not having made a more liberal incision in the abdominal walls for exploration, and into the tumor, by which it could have been evacuated more thoroughly, and which also would have enabled him to have lifted out more of the cyst wall and removed it. He believed that the patient's death was caused primarily by the noxious influence which all abdominal operations are apt to exert upon the kidney secretion, and, secondarily, by the septic processes in the contents, and that this latter could have been diminished by the removal of a large portion of the cyst. This would also lessen the chances of recurrence of such growths.

In the second place, it had been stated that kidney complications were more liable to occur in operations done under the spray of carbolic acid than when carbolic acid is not used. He did not think that the carbolic spray in this instance was a factor in the produc-

tion of a fatal result, as it gave out early in the operation; moreover, only a space of two and a half inches of cyst wall was exposed to its influence in even this short time. The renal symptoms occurred prior to the use of the spray employed when the dressings were changed.

Dr. G. A. Peters remarked that he was able to get a pulsation between the two large tumors, and regarded them as a single cyst.

CORRESPONDENCE.

DUDGEON'S SPHYGMOGRAPH.

To the Editor of The Medical News.

Sir: In a review of Bramwell's work on *Diseases of the Heart and Thoracic Aorta*, in the *American Journal of Medical Sciences* for January, 1885, "J. C. W.," after stating that the author gave preference, in writing of sphygmographs, to "the convenient and portable little instrument of Dudgeon," goes on to say, "We confess that the latter has been a disappointment to us." This comment induces me to think it worth while to call attention to the following slight addition which I have made to the instrument:

In the specimen of Dudgeon's sphygmograph which I obtained, attachment to the wrist was made by a strap and buckle. In adjusting the strap, I found difficulty in getting the proper degree of pressure, and in avoiding displacement of the apparatus. These difficulties I have obviated by the use of a small tourniquet placed upon the strap. With this addition the instrument is very easily applied.

The cost of the instrument in London is £2 2*s*, in New York (imported) $25. It would seem from these figures that it might be made here and sold, tourniquet included, for $20 or less. Its simplicity of construction (any watch-maker could repair it), cheapness, compared with the $40 Pond or $75 Marey instruments, etc., and with the above-mentioned addition, its ease of application, are very material advantages. Yours truly,

R. Van Santvoord, M.D.

26 E. 125th Street, N. Y City,
March 6, 1885.

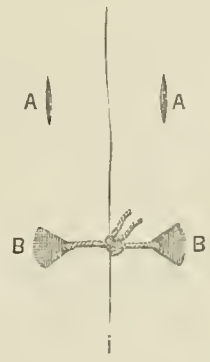
NEW INVENTIONS.

DESCRIPTION OF THE FLAT-CURVED NEEDLE AND OF A SUITABLE NEEDLE-HOLDER.[1]

By DR. HAGEDORN,
of Magdeburg, Europe.

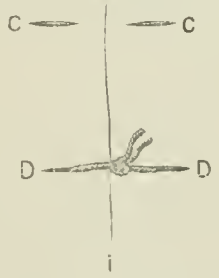
The needles which were formerly used for surgical sutures were either round or oval. They were curved on the surface flat, with a double cutting edge, and finished to a sharp point. The cutting edges and the flat surface were in the same plane. The small wound made by the puncture of the needle lay parallel with the edge of the united wound, as in Fig. 1, A. Such a punctured wound was, by tying the suture, converted into a triangular wound (see Fig. 1, B), and formed often a small fistula when the wound did not heal by first intention. As the needle point is smooth on the concave side of the curve, it loses strength and power of resistance, and is bent in hard tissues out of the course it was intended to follow. Besides this we have not had a needle-holder which would hold firmly and securely the needle without frequently breaking it.

Fig. 1.



The new needle, invented by Dr. Hagedorn, differs very much from the old needles. The sides are flatter, wider, parallel to one another, and also strong from point to eye. The anterior concave and posterior convex surfaces are smaller. The needles are also bent on the edge, and therefore are capable of withstanding more strain than other needles, which are bent on the flat surface. At the point the cutting edge is oblique on the convex side of the needle. The lower or inner border of the cutting edge is straight. The cutting edge is two or three times as long as the needle is wide. The needle point has nearly the shape of a broad cataract knife, if you suppose the back to be thick. This is important and necessary, because then the point of entrance of the needle remains in the same relation to the wound, and the cutting edges of the needle will produce widening of the canal through the opposing edges. If the point were lancet-shaped, strong pressure or accident might cause the needle to cut a canal undesirably close to the edge of the wound, or even through the edge. The puncture of this needle is a slit at right angle to the edge of the wound, like the button-hole on a coat (Fig. 2, C), which is closed by the knot on the thread. In many cases this flat needle will do less injury in suture of the nerves and tendons, which is not

Fig. 2.



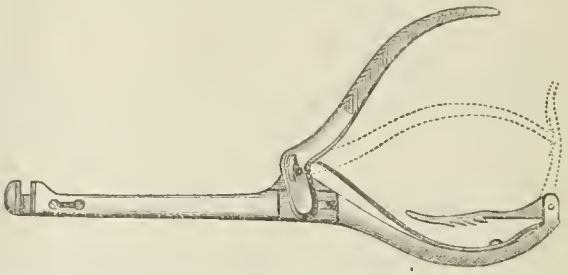
[1] Translated by R. S. Sutton, of Pittsburg, Pa.

unimportant. Moreover, this needle is easy to sharpen, because the point and cutting edge lie in the same line. It cannot be injured by pressure, and is easier to carry about. Only those needles for intestinal suture have an entirely round point, instead of a cutting edge. The eye on these flat needles can be made larger. It is a large, well-proportioned, wide, oval opening. Moreover, the end of the needle containing the eye is wedge-shaped, the outer end tapering off thin. On account of this, a strong double thread will follow the needle without difficulty through the canal it makes. On account of its construction, the needle can be fastened on any surface with security and firmness, and is very easily used (Fig. 3).

All the needle-holders now used secure curved needles in this manner, so that the flat surface of one jaw rests upon the concave surface and the other on the convex surface; therefore, by strong pressure, the needle is easily broken, and with weak pressure the needle slips out of the holder. This new, unique needle-holder presses on the broad sides of the above-described flat needles, and as the jaws of the holder remain continually parallel with each other, all flat needles of any curve can be fastened in the same manner; and breaking of the needle, by the strongest pressure with the needle-holder, is not possible. The needle can be fastened so well that one may hold it as if in a handle, and yet it is easy to loosen it. No other needle-holder fastens and fixes the needle at any desirable point with such a firm grip, and it is just as easy to catch it and hold it at the point. With some experience, it is possible just as easily to seize the needle with the needle-holder as to use another instrument, or the hand to assist in seizing it. In sewing, when the point of the needle has gone through one side of the wound, the point of the needle can be grasped by the holder without risk. One not only prevents accident by drawing the needle through, but protects the surrounding soft parts from injury, which is important in sewing in a cavity. Hence it is possible that the holder seize the needle from its concave border, and, while the cutting edge lies on the convex side, both the cutting edge and point are secure from any pressure.

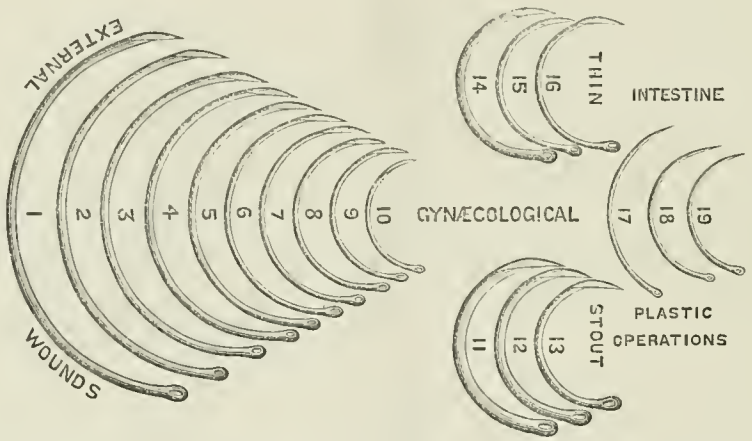
The needle-holder (Fig. 4) is made from a small piece of iron, ending in a handle, to which is attached a second piece, shorter and movable. The two pieces at their front ends form the jaws of the holder, which stands at

Fig. 4.



right angles to the axis of the instrument. The inner surfaces of the jaws are plated with copper. The movement of the two pieces on one another opens and shuts the jaws. This action is produced by means of a movable handle acting as a lever, which is fastened by a joint to the immovable handle. A serrated snap, which can be used or not, binds the two hand-grips together. Strong pressure with the full hand is sufficient to fasten any flat needle. The thick needle is firmly held at the first tooth of the snap; thinner ones by the lower teeth. Slight pressure of the little finger on the end of the snap easily loosens it and lets the needle loose. One must remember that the needle lies in the long diameter of the jaws, and lies firmly fixed on the piece of iron between the jaws. Therefore the needle has an additional support, and cannot change the position of its concave side, which it is inclined to do in cutting through. Moreover, the curved needle is easily adjusted, if one brings the jaws of the holder against the concave side of the needle, as is proper, and then turns the holder a little to the right before fastening the needle in the jaws. *Then only, if the needle is fastened in this manner, and the eye end of the needle shaft lies against the piece of iron behind the jaws, is the fastening of the needle absolutely safe.* The holder takes in little space, and is easily handled.

Fig. 3.



But for our particular suture, what is already said is not sufficient, if one wishes to apply a suture deep in a cavity in the sagittal plane of the body, for instance in a vesico-vaginal fistula high up. For such cases the sides of the

jaw, and consequently the opening between, stand obliquely, firmly fixed to a long handle; in this way a very oblique opening between the jaws is obtained. By reason of the obliquity of the opening, it is possible to apply such a suture if one will only turn the handle a little to the side. The catching and holding the point of the needle by this oblique opening between the jaws is not so easy as with the other holder, but is sufficiently easy after a little practice. For the various purposes, longer or shorter holders will be required.

1. The ordinary, 6½ in. long, strong holder, of which the mouth is $\frac{8}{25}$ in. wide, and ¼ to ⅓ in. deep, is sufficient for all ordinary surgical purposes, and can be used daily for years without repair.

2. The smallest, 5 in. long, holder, of which the mouth is ¼ in. wide and ⅓ in. deep, is for plastic and ocular operations, as well as for intestinal operations.

3. For practising physicians, who prefer to combine in one instrument the advantages of both needle-holders, not requiring to sew so much, an intermediate size would be desirable, which is 6 in. long, and in the mouth $\frac{7}{25}$ in. wide, and ¼ in. deep.

For gynecological and operations in deep cavities, the following sizes are suitable:

4. One, 8 in. long in the mouth, $\frac{7}{19}$ in. broad, and ⅓ in. deep; and,

5. One, with oblique mouth, $8\frac{2}{5}$ in. long; in the mouth $\frac{9}{25}$ in. wide, and $\frac{8}{25}$ in. deep.

As the flat curved needles, made in every form, possess many advantages which other needles do not possess, they are used in every form and of every strength; so this holder, with suitable needles included, will be found a suitable sewing instrument for any demand. In practice these needles have already found approval. Prof. Bardeleben (text-book for surgery and surgical operations, 8th edition, 1879, vol. i., addition to page 125) says, "If one perforates the margin of a wound with a double-edged cutting needle, the small wound produced is parallel with the edge of the wound, and gaps, in a triangular form, when the sutures are secured. One should always introduce a straight needle, so that one of the cutting edges looks towards the wound, the other away from it, and the wound through which the suture passes should stand at right angles to the wound when closed. To do the same with curved needles, Hagedorn has contributed an excellent apparatus, in which only the point and convex side of the needle cuts, and the whole results from side to side is flat, and a needle-holder accompanies these needles."

Prof. Fritsch (*Krankheiten der Frauen*, 2d ed., page 112) says: "As a needle-holder for all gynecological operations, I recommend highly Hagedorn's needle-holder. After many years of experiment, and having constructed many instruments myself, I have turned away from all, my own included. I cannot too highly recommend Hagedorn's needle-holder to the gynecologist. The needle-holder with straight mouth is employed for plastic operations; the one with the oblique mouth is to be preferred in operating in deep cavities and on irregular fistules, Fig. 56."

Prof. Olshausen writes, in his recently issued *Klinishen Beiträgen zur Gynäkologie und Geburtshülfe*, page 32, concerning operations on the cervix uteri, "The most useful needles to be recommended for these operations are the flat Hagedorn's needles, with an appropriate needle-holder. These only are able to afford the many demands which will be made by the severe bending pressure in operations in dense cervical tissue."

In Dr. Wittelhöfer's *Wiener med. Wochenschrift*, No. 33, 1883, Dr. Riedel, Oberartz der Chirurg of a department of the city hospital in Aix la Chapalle, expresses himself concerning utero-vesical and vesico-vaginal fistulas: "I use exclusively for sutures the Hagedorn's holder, with oblique mouth, and his flat needles. I do not think that any one who has worried himself with Simon's and other needle-holders will ever abandon this beautiful instrument, which is extraordinarily useful in all operations in deep cavities."

NEWS ITEMS.

MONTREAL.

(*From our Special Correspondent.*)

Ontario Anatomy Act.—For some years past there has been a great scarcity of subjects for anatomical purposes in the medical schools of Toronto. The students have yearly increased, but the amount of anatomical material has decreased. Never was it so inadequate as during the present session. To remedy this state of affairs a revised Anatomy Act has been framed, and will be shortly introduced into the Provincial Legislature. It provides that the bodies of those dying in public institutions, or found dead and not claimed by relatives or friends who are willing to bear the funeral expenses, shall be handed over to the medical schools for anatomical purposes. As during the past year over one hundred corpses were buried at the expense of the City of Toronto, it is thought that if this amended act passes the supply of anatomical material will hereafter be abundant.

The Annual Examination for the license of the College of Physicians and Surgeons of Ontario commenced at Toronto and Kingston on Tuesday, April 7th.

Dr. Lovell has been appointed Warden, and Dr. O. S. Strange, Surgeon, of the Kingston Penitentiary.

The Hon. Dr. Robitaille, ex-Lieutenant-Governor of the Province of Quebec, has been appointed to the Dominion Senate.

Nephro-lithotomy.—Prof. L. McLane Tiffany performed the operation of nephro-lithotomy on February 21st, at the Hospital of the University of Maryland, upon a male, aged 26. The stone, which weighed 556 grains, was removed from the pelvis of the right kidney. The *Maryland Medical Journal* reports the patient as doing well.

Bellevue Hospital Medical College.—The Twenty-fourth Annual Commencement of this Institution was held in the Metropolitan Opera House, New York, last Monday evening. Ex-Congressman Dorsheimer delivered a short address, in which he referred to the new pathological laboratory, built through the generosity of Mr. Andrew Carnegie. Mr. Carnegie subsequently delivered the address to the graduates. He was received by the class with a treble cheer, to which the audience added their applause. Dr. Isaac

E. Taylor conferred the degree of M.D. upon one hundred and thirty-four graduates.

University of the City of New York.—At the Annual Commencement of the Medical Department of the University held on March 10, the degree of M.D. was conferred on one hundred and seventy-five candidates.

University of Tennessee.—At the Annual Commencement of the Medical Department of the University of Tennessee, held at Nashville, February 24th, the degree of Doctor of Medicine was conferred on fifty-nine graduates of the institution.

University of Nashville.—The degree of Doctor of Medicine was conferred upon one hundred graduates of the University of Nashville and Vanderbilt University at the annual commencement, held at Nashville February 26th.

Memphis Hospital Medical College.—The Fifth Annual Commencement of the Memphis Hospital Medical College took place on February 25th. Thirty-three graduates received the degree of M.D.

The Arkansas Industrial University.—The Sixth Annual Commencement of the Medical Department of the Arkansas Industrial University, at which eight graduates received the degree of M.D., took place at Little Rock, March 4th.

Court Martial of Ex-Surgeon-General Wales.—The court martial to try Ex-Surgeon-General Wales, of the U. S. Navy, on the charges of culpable inefficiency and neglect of duty, met on Monday, and upon the request of counsel adjourned until April 14th, to give time for preparation of the defence.

Marine Hospital Service.—The Secretary of the Treasury, on Tuesday last, appointed Surgeons Bailhache, Purviance, and Austin, a board to examine applicants for appointment as Assistant-Surgeon in the Marine Hospital Service, to meet in Washington on March 23.

Dr. Osler's Gulstonian Lectures.—This year's lenten lectures at the Royal College of Physicians, London, were opened on Thursday, February 26th, by Dr. Osler, of Philadelphia, who choose for the subject of his Gulstonian Lectures the fascinating disease known as ulcerative endocarditis. His first lecture was devoted to the naked eye and microscopic pathology of the affection, its clinical history and etiology being left for discussion in the lectures to be delivered on Tuesday and Thursday in the following week. The lecture was mainly *ex tempore*, lasted the ideal forty-five minutes, and was unusually well attended. Dr. Osler, as might have been expected, was most cordially greeted, and there can be no doubt that his lecture was such as was well worth while his coming across the water to deliver. —*London Medical Times*, February 28, 1885.

Koch's Laboratory.—Under the terms of the liberal grant of money made by the German Government for the prosecution of his investigations of the cholera germ and related subjects, Dr. Koch is to admit thereto small classes of the medical men of Germany, for the purpose of studying the comma-bacillus and its method of cultivation. Through the efforts of Minister Kasson and the courtesy of Prince Bismarck, Dr. George W. Lewis, of Buffalo, N. Y., has also been admitted to these classes, and in the current number of the *Buffalo Medical and Surgical Journal* he publishes an account of Dr. Koch's cultivation experiments.

Obituary Record.—Died, in this city, on March 10, Ellerslie Wallace, M.D., Emeritus Professor of Obstetrics and Diseases of Women and Children in Jefferson Medical College, Philadelphia. Dr. Wallace was born in this city on June 15, 1819. He received his education at Bristol College, and was engaged for a time in the profession of civil engineer. He studied medicine in the office of his brother, Joshua Wallace, who, at the time, was Demonstrator of Anatomy in the Jefferson College, and graduated at that institution in 1843. After graduation Dr. Wallace was appointed Resident Physician at the Pennsylvania Hospital. In this place he remained three years, when in 1846, he was selected as Demonstrator of Anatomy in Jefferson College, a position which he held until 1863. In the latter year he was elected to the chair of Obstetrics, rendered vacant by the resignation of Dr. Charles D. Meigs, and he filled the duties of that position until June 1883, when he retired on account of failing health. He also filled the office of Dean at the College. Dr. Wallace had been in bad health for some months past, but the immediate cause of death was an erysipelatous affection of the face and head. Dr. Wallace was a fluent lecturer, and a popular teacher, and was much beloved by his class.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 3 TO MARCH 9, 1885.

Byrne, Charles C., *Major and Surgeon.*—Ordered to Department of the East, on expiration of his present leave of absence. —*S. O. 50, A. G. O.*, March 3, 1885.

Brown, H. E., *Major and Surgeon.*—Granted leave of absence for one month, with permission to apply for two months' extension.—*S. O. 48, Department of the East*, March 6, 1885.

Woodruff, Ezra, *Captain and Assistant Surgeon.*—Ordered for duty at Fort Maginnis, Montana Territory—*S. O. 23, Department of Dakota*, February 25, 1885.

Porter, J. Y., *Captain and Assistant Surgeon.*—Sick leave of absence further extended fourteen days on account of sickness. —*S O. 51, A. G. O.*, March 5, 1885.

Ewing, C. B., *First Lieutenant and Assistant Surgeon.*—Having relinquished unexpired portion of leave of absence, ordered for temporary duty in the field.—*S. O. 23, Department of the Missouri*, March 2, 1885.

Raymond Henry I., *First Lieutenant and Assistant Surgeon* (recently apppointed).—Ordered for duty in Department of California.—*S. O. 50, A. G. O.*, March 3, 1885.

ORIGINAL LECTURES.

GULSTONIAN LECTURES.
ON MALIGNANT ENDOCARDITIS.

Delivered at the Royal College of Physicians, London, on Thursday, February 26, 1885.

BY WILLIAM OSLER, M.D.,

PROFESSOR OF CLINICAL MEDICINE AT THE UNIVERSITY OF PENNSYLVANIA, PHILADELPHIA.

LECTURE I.

MR. PRESIDENT AND GENTLEMEN: It is of use from time to time to take stock, so to speak, of our knowledge of a particular disease, to see exactly where we stand in regard to it, to inquire to what conclusions the accumulated facts seem to point, and to ascertain in what direction we may look for fruitful investigations in the future. With your permission, Sir, I propose to do this in the case of that most interesting disease generally known as ulcerative endocarditis, a disease the phenomena of which were first clearly explained by the late Dr. Kirkes, from whose investigations, in 1851–52, we date our accurate knowledge of the affection. Some of those who listen to me to-day can doubtless recall, and recall with pleasure, the Gulstonian Lectures of 1851, in which Dr. Ormerod dealt so fully and so ably with valvular affections of the heart; but a reference to them will show how much the past twenty-five years have done to widen our view of cardiac disease, more particularly in regard to the effects of emboli and the association of valvular inflammation with grave constitutional disorder, and the probable connection of the disease with the presence of microörganisms. By the labors of Drs. Ogle, Wilks, Simpson, Moxon, Bristowe, and others, in this country; of Charcot, Vulpian, and Lancereaux, in France; and of Virchow and a host of observers, in Germany; a large amount of material has been accumulated, and we may assume that the etiological, clinical, and anatomical characters of the disease have been fairly well ascertained, and that we have got about as far towards a full knowledge of the affection as the ordinary means at our disposal will permit. The inquiry now enters upon another stage, and it remains for experimental investigation to determine, if possible, the relation of the endocarditis to those diseases with which it is most frequently associated. This being the case, the present time has seemed to me a favorable opportunity to summarize our knowledge to date, and for this purpose I have reviewed the records of over two hundred cases, which, from the description of the symptoms and lesions, were evidently of the type of malignant endocarditis; and these, with the considerable experience I have had at the General Hospital at Montreal, may perhaps enable me to give a somewhat more comprehensive account, in some respects, than has yet been attempted.

In discussing the subject of endocarditis we are met at the outset by difficulties of nomenclature and classification. The designation *acute* may be used to indicate those forms which are accompanied by proliferation of and exudation upon the endocardial surface, with or without loss of substance, as opposed to *chronic*, in which there are sclerotic changes without vegetations. Subdivisions of the acute form have been arranged on an anatomical basis as the terms *plastic*, *papillary*, *verrucose*, *fungous*, *ulcerative*, indicate. On the other hand, from an etiological point of view, the forms of endocarditis are as numerous as the diseases in which it occurs, and we constantly hear the expressions *puerperal*, *rheumatic*, *scarlatinal*, etc. Some speak of primary and secondary forms, while from a clinical standpoint they are arranged in two classes, simple and grave. Anatomically there appear to be no very essential differences in the various forms of acute endocarditis. Between the small papillary excrescence and the huge fungating vegetation with destructive changes all gradations can be traced, and the last may be the direct outcome of the first; the two extremes indeed may be present in the same valve. They represent different degrees of intensity of one and the same process. A classification of cases based on the ordinary macroscopic characters of the inflammatory products into warty or verrucose and ulcerative will in many instances group together cases widely different [in their clinical aspects, and contrariwise, a clinical subdivision into cases of simple and cases of malignant endocarditis by no means of necessity implies that the lesions in the former case are all of the plastic or warty variety, and in the latter of the ulcerative or destructive. The term *ulcerative* has come into very general use to describe the grave form, and it expresses well an anatomical feature present in a large proportion of cases; but in others it is very inapplicable, as there may be no actual loss of substance, and no more destruction than occurs in the verrucose form; and, on the other hand, there may be great destruction and ulceration from causes of an entirely different nature. The numerous other terms employed, *septic*, *infectious*, *diphtheritic*, *mycosis endocardii*, *arterial pyæmia*, while each expressing some special feature, and so far suitable, have never come into very general use. On the whole, it seems to me that the names *simple* and *malignant*, which we use so often to separate the milder and severe forms of many diseases, might appropriately be employed in describing the cases of acute endocarditis; the *simple* being those with few or slight symptoms, and which run a favorable course; the *malignant* the cases with severe constitutional disturbance and extensive valve lesions, whether ulcerative or vegetative, the term being more clinical than anatomical.

Malignant endocarditis occurs under the following conditions: 1. As a primary disease of the lining membrane of the heart or its valves, either attacking persons in previous good health or more often attacking the debilitated and dissipated or those with old valve

lesions. 2. As a secondary affection in connection with many diseases, particularly rheumatic fever, pneumonia, scarlet fever, diphtheria, ague, etc. 3. As an associated condition in septic processes, traumatic or puerperal. We shall discuss first the anatomical characters, then the clinical features, and lastly the etiological and pathological relations.

The lesions of malignant endocarditis are by no means uniform, and may be vegetative, ulcerative, or suppurative; and these various forms may occur alone or in combination. The belief that there is always ulceration has led to some confusion, and we must recognize that there are cases with the clinical history of the malignant form in which, post-mortem, the valvular condition has been that of a severe vegetative or verrucose endocarditis. Such a case was a lad aged eleven, a patient of Dr. Molson's, from whom I obtained the specimen which I pass round. He had chorea in July, 1880, the second attack. Rapid movement and recovery under Fowler's solution five minims every four hours hypodermically, took place. There was a slight murmurish condition of the first sound. When seen again on March 3, 1881, the chorea had returned, having begun ten days before. The patient improved until the 10th, when he began to get feverish; had exacerbations each evening; temperature rising to 104° F. He became unconscious. There was slight paresis of the left side, and death took place on the 16th. The temperature on the 15th was nearly 106°. There were irregular, soft, grayish-white vegetations on the mitral valve, infarcts in spleen and kidneys, and a small spot of red softening in the right corpus striatum. These photographs from a case of Dr. Musser's, illustrate a more advanced condition of the same kind; the vegetations were larger and more abundant, and some were a little irregular and soft on the surface, but unless a mass was removed no actual loss of substance was seen. Even in the smallest vegetation there is some destruction of endocardial tissue, if only of the endothelium and superficial layer, while the larger outgrowths are more deeply set in the valve, or may involve the entire thickness. More commonly with or without vegetations there is ulceration, the frequency of the occurrence of which has given the name most often attached to this form of endocarditis. The loss of substance may be superficial, involving only the endocardium, or it may be deep and destructive, leading to perforation of a valve, of the septum, or of the heart itself. On the valves extensive outgrowths usually accompany the process, and may conceal the ulcer or project as fungating masses from its edge, as is well illustrated by this colored drawing. In many instances the process appears simply ulcerative, without any vegetations to speak of. In the slightest form only a superficial abrasion exists, perhaps scarcely recognizable, in others a process of erosion may go on by which half a valve may be destroyed, or there may be (as shown in this drawing) a deep excavation extending beyond the valves and destroying the muscle substance of the heart, leading to perforation of the septum of the wall of the ventricle. These are well-known features, however, upon which I need not dwell. In two instances I have seen superficial necrotic changes without ulceration or vegetations, circumscribed patches, the size of a sixpence, opaque yellow-white in color, resembling the necrotic pleura, over a pyæmic infarct of the lung or portion of dead peritoneum at the base of a deep typhoid ulcer. Doubtless these would in time have formed ulcers. I find this condition noted by one or two observers. Lastly, the process may be suppurative, in which case the deeper tissues of the valve appear first involved and the endocardium only implicated by contiguity. The occurrence of small abscesses at the base of extensive vegetations is not uncommon, but there are also instances in which the suppuration seems the initial step. The combination of ulcerative and fungating outgrowths is perhaps the most common condition. The vegetations vary a good deal in appearance and consistence. Soft grayish-white masses with roughened friable surfaces, to which thin blood-clot adheres, are numerous, or there may be large cauliflower excrescences with deep jagged fissures; or again, long pendulous stalactitic masses. In the latter form we often see, as Dr. Moxon pointed out, the effects of friction, and such a long vegetation from an aortic cusp may produce by contact a whole series of smaller outgrowths along the ventricular wall. The pressure of the valves against each other and the action of the blood tend to loosen and break the vegetations, and one can sometimes see where masses have been torn off either entire or by a gradual process of disintegration. Considering the force with which the valves come together it is curious that the soft vegetations, occupying, as they generally do, the lines of closure, can resist the constant compression to which they are subjected. Some vegetations present a remarkable greenish-gray or greenish-yellow color. Changes in a conservative direction may go on when the disease is much prolonged. Fibroid induration may take place in the deeper parts, while the superficial portions remain unchanged and necrotic, perhaps also getting a little harder and shrinking. Such a process can be seen in this specimen of endocarditis from an ox, in which there were most extensive vegetative and destructive changes. Not unfrequently the vegetations are gritty from the deposit of lime salts, which may take place in very acute cases, and is not necessarily an indication of age. It is interesting to note how often inorganic material is deposited in the neighborhood of microörganisms, as here on the endocardial outgrowths, in the tonsillar crypts, and about the tufts of actinomyces. Two conditions must be distinguished from the lesions of malignant (mycotic) endocarditis; the atheromatous degeneration in sclerotic valves, which leads to ulceration and extensive destruction of segments—a process which has nothing in common, except in its effects upon the valves, with the acute ulcerative changes above described, but is similar to the atheromatous processes in the aorta. It must not be forgotten, however, that an acute mycotic process may be engrafted, and indeed often is, upon old sclerotic valves, the seat of atheromatous changes. The firm white globular thrombi of the auricular appendices and of the interstices of the columnæ carneæ of the ventricles, have sometimes an appearance closely resembling endocardial outgrowths, and when softened in the centre and ruptured the resemblance may be very close indeed. It is possible that the granular débris of an atheromatous abscess or a softened thrombus may possess irritating properties when discharged into the blood.

Histological characters.—The study of a small fresh endocardial vegetation shows it to be made up of cells derived from the subendothelial layer, round and fusiform, which by their proliferation have produced a small nodular projection on the surface of the endocardium. Varying with the rapidity of the growth, the mass will present the characters of a soft granulation tissue or a tolerably firm fibrous outgrowth. Usually the round cells predominate, but there may be many elongated, spindle-formed cells with three or four processes. What part the endothelium plays in this growth has not been determined. Tiny outgrowths may be seen in which the process appears to be entirely subendothelial, but usually before the mass attains any size the smooth surface is lost, and there is deposited upon it a cap of fibrin in the form of a granular, sometimes stratified, material, of variable thickness. Though this resembles an ordinary coagulable exudation, it is probably deposited directly from the blood, and is of the nature of a thrombus. Upon and in this layer may be found, sometimes in large numbers, those remarkable little bodies which have so long been known, when collected together, as Schultze's granule masses, and which have of late become so prominent as the blood-plates of Bizzozero and the hæmatoblasts of Hayem. Occasionally they are very abundant, and I have seen soft warty vegetations composed (superficially) in great part of them. As their connection with endocardial and endarterial outgrowths has not, so far as I know, been referred to, I may be permitted to call attention to these two drawings, which further illustrate this point. The first represents the aorta from an old man dead of carcinoma, in which just above the bifurcation three irregular masses are shown, one nearly an inch in length, which projected fully a quarter of an inch from the intima of the vessel. They were attached to atheromatous ulcers, were soft, grayish-white in color, and were composed exclusively of the elements of Schultze's granule masses, with fibrin fibrils, and here and there a few white corpuscles. The second drawing illustrates a small aneurism of the aorta, which has perforated the œsophagus. On the wall of the sac the artist has represented a number of irregular whitish lines, which were narrow elevated ridges, also made up microscopically of these small discoid elements, the connection of which with fibrin formation has been so strongly insisted upon by Bizzozero. Scattered in and beneath the fibrinous exudation are numerous small granular bodies, which have the appearance and reaction of micrococci.

The larger vegetations, more characteristic of malignant endocarditis, consist of a granular material composed of altered and dead tissue elements, fibrinous exudation, and colonies of micrococci; the deeper parts present the appearance of a granulation tissue, while at the attachment in the valve there is always more or less infiltration and increase of the cell elements. The granular substance is structureless, and resembles diphtheritic exudation, the resemblance at times being so close that one can readily understand the application of the term "diphtheritic" to the inflammation. It may be distinctly laminated, and with a high power fine filaments can be seen, though usually the granules conceal all appearance of structure. Strands of translucent material may occur throughout the mass, as if portions had undergone a sort of hyaline transformation. In some instances this is very marked. Pale spheres filled with granules also occur, and may be very abundant. They have been described as colonies of micrococci, but some regard them as altered endothelial elements. I have seen them too numerous to be explained on this view. At the attachment of the vegetation there is a zone of tissue deeply infiltrated with leucocytes, and deeper still the tissue elements of the valve present an increase of nuclei and cells. The destruction of tissue appears to result in two ways: first, a gradual extension inwards of the necrotic process, doubtless induced by the micrococci; secondly, the softening and separation of valve tissue caused by the rapid development of leucocytes at the base of the vegetation.

The micrococci are constant elements in the vegetations. All granules of a uniform size met with in the sections are not microörganisms, nor, indeed, are all which stain by some methods recommended for the detection of these bodies. By far the most satisfactory method is that of Gramm,[1] in which the section after staining in gentian violet, is transferred for a few minutes to a dilute solution of iodine and iodide of potassium, and then to the alcohol, when it is found that the color has been extracted from all tissue elements and nuclei, leaving only the microörganisms stained. They vary a good deal in number and arrangement, and may be scattered singly in the granular substance or arranged in groups. They are usually very numerous at the deeper part of the vegetations, just where the structureless material joins the granulation tissue, and they may penetrate deeply into the substance of the valve. Sometimes the smaller vegetations seem made up exclusively of them. Several of my specimens appear to confirm the view of Klebs,[2] that the micrococci lodge first on the endocardium and penetrate into the substance, often as distinct columns. In their immediate vicinity there is a zone of necrosis, and beyond this an accumulation of leucocytes and signs of reactive inflammation. The microörganisms found in connection with malignant endocarditis are not all of the same kind. Klebs distinguishes two forms, one met with in septic, and the other in rheumatic cases. In some instances the micrococci are all arranged in zoöglœa-like masses, in others, particularly the septic cases, they are in chaplets. Some present distinct capsules. Small elongated bacilli have also been found; I have seen them in one instance—short, stout rods often joined in pairs. Delafield and Prudden[3] have recently noted the presence of bacilli in the vegetations of a very acute case of malignant endocarditis. Cornil, in a recent lecture,[4] stated that the bacillus tuberculosis had been found in the vegetations on the valves in cases of phthisis, and expressed the opinion that before long we should have accurate knowledge of a variety of microörganisms in endocarditis depending upon the nature of the primary disease. By culture experiments alone can we hope to have the question settled.

The following figures give an approximate estimate of frequency with which different parts of the heart are affected. The aortic and mitral valves were affected

[1] Fortschritte der Medicin, Berlin, Bd. i.

together in forty-one cases, the aortic valves alone in fifty-three, the mitral alone in seventy-seven, the tricuspid in nineteen, the pulmonary valves in fifteen, and the heart-wall in thirty-three. The right heart is rarely affected alone, in only nine instances, in which five the tricuspid and four the pulmonary valves were involved. The valves are most often attacked along the lines of closure, as in simple endocarditis, the auricular faces of the mitral flaps and the ventricular surfaces of the aortic cusps suffering most severely. Mural endocarditis is most often seen at the upper part of the septum of the left ventricle, just below the aortic ring, in which situation some of the most extensive and deep cardiac ulcers occur, leading to perforation of the septum. Next in order is the endocardium of the left auricle on the postero-external wall, as noted by Lepine.[1]

The local effects of the ulcerative changes are important. Perforation of a valve segment is extremely common, sometimes there is a clean-cut, punched-out hole with scarcely any irregularity of the edges; more frequently, however, there are great fungous vegetations which completely close and conceal the perforation. Erosion of the chordæ tendineæ is frequently met with, and an entire group passing to the papilla may be destroyed, the ends curled and encrusted with vegetations. Ulceration of the heart muscle leading to perforation of the septum or of the wall of a chamber is a much less frequent occurrence. I have collected notes of eleven instances; three of the septum close to the aortic ring. Ulcers at the aortic ring perforated the left auricle in three instances, the right auricle in one, and the right ventricle in one. In a remarkable case of Dr. Stephen Mackenzie[2] the left ventricle was perforated by an ulcer at the apex. In a case of Dr. Curnow,[3] the ulceration extended between the coats of the aorta, and then perforated into the lumen of the vessel, and in one of the Montreal cases there was perforation of an aneurism of the aorta by ulceration, an instance of extensive ulcerative endarteritis with the production of multiple aneurisms. Another common result of ulceration is the production of valvular aneurism. The anterior flap of the mitral is most frequently affected, and then the aortic cusps. In the records of the cases which I have reviewed, I was surprised not to find this condition noted oftener, only in about 12 per cent. of the cases; but in very many cases the record of the anatomical condition was meagre. I shall not refer further to this interesting point, as Dr. Legg has dealt with it very fully in a recent lecture at this College.[4] I may observe, however, that the atheromatous ulceration is also a frequent cause of aneurism of the valves.

It was Sir James Paget,[5] I think, who first referred to the frequency with which sclerotic and malformed valves are attacked by acute disease. Chronic valvulitis is met with in a large number of cases of malignant endocarditis. The records which I have examined give only a percentage of about twenty-five, but the condition of the valves, except as regards ulceration, was often omitted, and this represents a very much smaller percentage than actually occurs. In more than three-fourths of the Montreal cases sclerotic changes were present, and Dr. Goodhart found[1] in a series of sixty-nine cases that sixty-one presented old thickening of the valves. In very many of the cases the condition of fusion of two of the aortic cusps was present. This abnormality is almost invariably accompanied by sclerotic changes, and to the existence of these is probably due the frequency with which they are attacked by ulceration. In seventeen instances of fusion of two of the aortic cusps, of which I have notes, there were ulcerative changes in eight, in two or three of an atheromatous nature.

In a few instances the aorta is involved with the heart. The most frequent site is the sinuses of Valsalva, the vegetations growing through the segments spread on to the aortic wall, or it is affected by friction. It is rare for the vegetations to extend into the arch. I have met with one remarkable instance of ulcerative endocarditis in which there was also ulcerative endarteritis, involving the arch and producing multiple aneurisms. The specimen which I here demonstrate was taken from a man about thirty, who had been the subject of syphilis and was known to have had aortic incompetency for some time. He was admitted to the General Hospital, Montreal, on June 4, 1880, with diarrhœa, chills, headache, cough, and fever. Temperature 104°. There were signs of pneumonia at the left base. He became delirious, a low typhoid condition supervened with chills at intervals, and death took place on July 1st. The aortic valves were curled and hard, and presented extensive recent vegetations, the arch of the aorta presented four aneurisms, three small, not larger than cherries, and one the size of a billiard ball. The small ones were not noticeable as aneurisms from the internal surface, but presented the appearance of fresh fungous vegetations, on separating which little slits could be seen leading to saccular dilatations of the middle and outer coats. The large aneurism was thin-walled with no laminated fibrin, and presented at the edges of the orifice and over the whole lining membrane of the sac, many grayish-green vegetations, some of which had perforated the sac and caused a rupture into the pericardium. It may be presumed that in this instance the ulcerations led directly to the production of the aneurisms, certainly in the case of the smaller ones, and the larger sac presented a condition of mycotic endarteritis unique in my experience of aortic aneurisms.

Of associated pathological changes we have, in the first place, those connected with some primary disease, to which the endocarditis is in the majority of cases secondary. Thus, in the endocarditis of septic processes there is the local lesion, a suppurating wound, a phlegmonous inflammation, or puerperal processes of a septic nature. In a very considerable proportion of cases there is evidence of recent pneumonia, in others rheumatic affections of joints, and in a few diphtheritic processes. In the group of primary cases the lesions are entirely those of endocarditis, local and general. In the second place, there are the extensive pathological changes due to embolism, and these constitute interesting features in the disease, and may produce a

very great variety of lesions in every portion of the body. I do not propose to deal very fully with these, but to call attention only to some special points. The cases may be divided into those without any embolic processes, cases in which the infarcts are simple, not suppurative, those in which there are innumerable suppurative infarcts, and cases in which some of the infarcts are simple and some suppurative. It is remarkable how variable these embolic features are. They may be entirely absent in well-marked malignant cases. They are not necessarily associated with suppuration; indeed, in a very considerable number of cases they present the characters of ordinary hemorrhagic infarcts, but in the traumatic and puerperal cases the infarcts are invariably septic. They may be few in number, only one or two perhaps in the spleen or kidney, or they may be in thousands throughout the various organs of the body. When suppurative, micrococci, in my experience, are always present; but the micrococci may exist in the vessels without inducing this change. In severe forms of the disease hemorrhages are very frequent upon the skin, serous and mucous surfaces. The cutaneous ones will be referred to again in connection with the symptomatology. They appear, in many instances, to be due to the effect of the poison, just as in other infectious diseases; in others they are undoubtedly embolic, and a minute necrotic or suppurative centre can sometimes be seen. In the membranes of the brain I have twice met with extensive superficial extravasation. Litten[1] has called attention to the frequency of retinal hemorrhages, particularly in the endocarditis of puerperal sepsis. In some instances there are innumerable miliary abscesses, more particularly in the heart and kidneys. They are often associated with hemorrhage, and the smaller ones look like little extravasations, but the presence of micrococci and suppuration can be easily determined in stained sections. The spleen is most often the seat of infarction, and next in order the kidneys. The lungs are usually affected when the endocarditis is on the right side, and there may be suppuration or even extensive gangrene, but even with destructive lesions of the pulmonary valves there may be no suppurative infarcts in the lungs, as in a case of Dr. Church.[2] Or again, as in a case of Dr. Moxon's,[3] there may be with aortic valvulitis suppurative infarcts in the lungs, and simple ones in the other organs. The gastro-intestinal canal may present very remarkable changes, due to the presence of numerous infarctions, from the size of a pin's head to a split pea. They are slightly elevated, grayish-yellow in color, often surrounded by a zone of deep congestion or extravasation, and on section may show a suppurative centre. Micrococci are present as in other biliary abscesses, and in several instances I was able to find small embolic plugs in the arteries of the submucosa. The abscesses may discharge and leave a small ulcerated surface. In the stomach there may be similar minute infarcts, and occasionally larger ones. Carrington[4] has described a remarkable case in which there was a gastric ulcer, apparently due to embolic process, in a case of severe endocarditis; and Magill,[1] a case in which the stomach was intensely inflamed, the mucous membrane at the greater curvature being black, almost gangrenous. The liver may present minute abscesses, and in a number of cases in which there has been jaundice degeneration of the cells has been observed.[2] The serous surfaces are often inflamed, pleurisy and pericarditis being not uncommon complications. The pericardium is most frequently affected in rheumatic cases, in which endocarditis and pericarditis may occur simultaneously. Pleurisy is met with chiefly in connection with the traumatic and puerperal cases, and also with pneumonia, which, as I shall show, plays such an important part in the history of this form of endocarditis. The cerebral lesions are of the substance and of the membranes. Embolic softening, simple or suppurative, is extremely common, and in very many cases head symptoms supervene, and there is paralysis of one side or the other. There may be a single embolus, producing extensive suppuration or red softening, or there may be multiple infarcts in various regions.

The meningeal complications of endocarditis have not received much attention. Considering the frequency with which it has occurred in the Montreal cases, five instances out of twenty-three, I was quite prepared to find such a large number as twenty-five cases—*i. e.*, in somewhat over twelve per cent. In the majority of these cases it occurred in connection with pneumonia. It is almost always cortical, but may extend to the base and involve the nerves, leading in one case, which I saw with Dr. Ross at the Montreal Hospital, to strabismus, and also to ulceration of the cornea from involvement of the fifth nerve. In rare instances the spinal meninges are involved, and the clinical picture may be that of an acute cerebro-spinal meningitis.[3] Acute suppurative parotitis was noted in three cases.

ORIGINAL ARTICLES.

A YEAR'S WORK IN LAPAROTOMY.

By WILLIAM GOODELL, M.D.,
Professor of Gynecology in the University of Pennsylvania.

From the subjoined table it will be seen that I have had during the past year twenty-two ovariotomies, making a total of one hundred and thirty-two cases. Of the former, ten were performed in the Hospital of the University of Pennsylvania, with three deaths; seven at my private hospital, with one death; and five at the home of the patient, with one death.

In eleven both ovaries were removed. Seventeen had adhesions, which in seven were of the most formidable character, requiring many ligatures and very careful and prolonged dissection. There were also four women whose ages were respectively sixty, sixty-one, sixty-three, and sixty-four years; of these one died.

In not a single instance did I refuse to operate, however low the patient. This statement will, I think, be borne out by the following brief history of the five fatal cases:

Case 118 was operated on in the Hospital of the University. Death ensued on the third day, from hospitalism, I believe, because the operation was not a difficult one and the adhesions were merely omental. There was considerable ascitic fluid and perhaps a drainage-tube should have been used.

Case 121 was that of a lady aged sixty-three, who had been worn down to a skeleton by a large tumor weighing about sixty-five pounds. She also had albumen in her urine, and was operated on in the Hospital of the University. There were very extensive and firm parietal and omental adhesions, which needed many ligatures. She did extremely well for sixty hours, when, without warning, she suddenly became comatose and died in five hours from acute uræmia. The autopsy revealed one kidney riddled with abscesses and the other affected with interstitial nephritis. The abdominal cavity was wholly free from inflammation.

Kidney disease is a frequent cause of death after ovariotomy. Yet I think that no ovariotomist would be justified in refusing an operation merely on that ground, unless the patient's condition were already a hopeless one from the renal lesions. But it is not always easy to determine whether the disease of the kidney is due to the pressure of the tumor or whether it exists independently. In suspected kidney trouble it would perhaps be safer to administer chloroform in the place of ether, which tends to arrest the action of these organs, and I greatly regret not having done so in this case.

Case 123, when first put in my hands was in an advanced stage of septicæmia, and I operated on her sheerly from a sense of duty, as her physician, Dr. J. W. Wilson, and the Resident Physicians of the Hospital of the University will, I am sure, attest. She gave birth to a child on July 24, and after her delivery a tumor was discovered by Dr. Wilson. It grew so rapidly, and the woman's health failed so much, that on August 22 he was obliged to tap, removing two and a half gallons of fluid. This operation, while relieving the woman from pressure symptoms, did not improve her health, which became worse and worse. On September 19th, she was carried to the Hospital of the University, never having left her bed from the day of her delivery. Her temperature was over 103°; her pulse never under 130. She had night-sweats, the glassy eyes of septicæmia, and two large bed-sores. She was also very pale and weak. On September 22d, with many misgivings that she would die on the table, and with every preparation made to avert such an end, I operated on her, being assisted by Drs. James F. Wilson, Joseph Stokes, and C. W. Richardson, and by my son. Several times during the operation she seemed to be dying, and hypodermic injections of ether, brandy, and the tincture of digitalis, were liberally used. The cyst weighed about fifty pounds, and was attached everywhere, to abdominal wall, intestines, and omentum. Its walls were rotten, and its contents gave off a sickening odor. Very little blood was lost, but the shock was too great, and she died fifteen minutes after being put to bed.

Case 130 was another forlorn hope. Five years previously, as Case 8 of my total series, this woman had been operated on by myself for a very large colloid cyst of the left ovary. A year ago her health began to fail coincidently with the appearance of another abdominal tumor. Early in December, when I first saw her, she was so thin, sallow, and reduced in strength, and the fluctuation was so obscure, that my diagnosis was colloid degeneration of the right ovary, probably malignant. On December 13th, I operated at the home of the patient, being aided by Drs. J. E. Bauman, of Telford; H. G. Groff and Vincent Z. Keeler, of Harleysville; Slifer, of North Wales; and by my son. On opening the abdomen, I found its cavity full of a thick jelly, which had escaped from the main cyst evidently some time before. The bowels, agglutinated together, were roughened with papillæ, and enveloped with this colloid material. In addition, the womb, broad ligaments, bladder, and the parietal peritoneum were studded with papillomatous masses. Even the pedicle, which was short, was so covered with papillomata that I had to scrape them off with my thumb-nail in order to find a place in which to lodge the ligature. I did not see her again, but Dr. Bauman informed me that the wound healed perfectly; no abnormal symptoms set in; yet she grew weaker and weaker, dying from sheer exhaustion on the sixteenth day after the operation.

This case is the only one in which I performed ovariotomy twice in the same patient. But I have at present under treatment a lady from whom, four years ago, I removed the left ovary for cystic degeneration, and in whom the right ovary is now rapidly enlarging. The liability of the remaining ovary to cystic disease, which in my cases amounts to a little over 1.5 per cent., strengthens me in the conviction that in women approaching the climacteric, both ovaries should, as a rule, with but few exceptions, be removed. Had this been done, my patient would not now be exposed to the risk of a second operation, and would have been saved grievous disappointment.

This case also makes my third one of colloid degeneration in which the sac had burst some time before the operation. In each the disease was evidently malignant. One survived the operation, and went home; but died a few weeks afterward with a reaccumulation of the colloid material in the peritoneal cavity, and a sprouting out of a crop of papillomata from the cicatrix in the abdominal wall. In the second one both ovaries were removed, and from great emaciation and weakness, the woman became plump and hearty. For two years she did extremely well. Then a tumor made its appearance in the left broad ligament. It gave much pain, caused obstinate costiveness, and rapidly exhausted her strength. I offered to make an exploratory incision to see what could be done, but she refused, and died not long afterward. The history of these cases goes to show that colloid cysts of the ovary are liable either to start with malignancy, or to

degenerate into malignancy, and should, therefore, always arouse suspicion.

Case 132, from the outset, held out but little prospect of success. Two months previously, the lady had been etherized by several physicians with a view to an operation; but, after a careful examination, it was not attempted. For diagnostic purposes, however, a hypodermic syringe was used to abstract a little of the fluid contents.

When I operated on her (December 21st), she had septic fever, with night-sweats, and her legs were greatly swollen. The tumor, not larger than a child's head, but bulging down into Douglas's pouch, proved to be a suppurating dermoid cyst of the left ovary. It was adherent at every point to the bowels, appendix vermiformis, broad ligament, pelvic fascia, and to the whole hind portion of the womb. In the stripping of the cyst off from the womb, the raw surface bled so freely that Paquelin's cautery had to be resorted to, and, in addition, some of the vessels were tied *en masse*, the needle penetrating uterine tissue. The pedicle was the left cornu of the womb, which was transfixed and tied. The patient did fairly well for a week, giving good promise of recovery; but on the eighth day she began to vomit green matter, and died in a few hours quite unexpectedly.

to occur in the abdominal cavity than within the sac, as in dermoid cysts.

A few words are needed about Case 126. She had a rheumatic heart and the goggle eyes of exophthalmic goitre. The operation was performed at the patient's home in the country on October 25th. On account of the cardiac disease ether was administered with great caution. The operation was an easy one; adhesions did not exist, and both ovaries were readily removed.

I did not see her again, but I learned by a letter from Drs. Meschter and Gerhard, her physicians, that she died on November 27th, thirty-three days after the operation, from inflammatory rheumatism and her cardiac affection. "She seemed to have perfectly recovered from the operation."

With regard to the causation of ovarian cysts, I feel more and more convinced that single life, sterility, or unfruitfulness, whether natural or enforced, has more to do with it than is generally supposed. Thus out of my 22 cases, there were 9 unmarried women and 1 widow. Of the married, there were 1 without a child, 1 with 1 child, and 3 with 2 children. These figures go to show that unless the cycle of reproduction is completed in woman she is plainly violating some great law of her being.

Number.	Name and Residence of Previous Medical Attendant.	Age.	Condition.	Number of Children.	Place of Operation.	Date of Operation.	Nature of Disease.	Result.	Remarks.

In my experience, dermoid cysts are very liable to have firm and extensive attachments, which make their removal far from easy. They are also very vulnerable, taking on inflammation on the slightest provocation. I have had two cases of a small cyst in Douglas's pouch in which violent inflammation followed the use of the aspirator, putting my patient's life in jeopardy, but fortunately ending in obliteration of the sac. In the present case, suppuration was probably due to the use of the hypodermic syringe. Several cases of fatal inflammation have also been reported after an analogous use of the hypodermic syringe in ovarian cysts. But in such cases, owing to the escape of a thinner fluid from the tense cyst, the inflammation is more liable

Of other laparotomies, I had one successful hysterectomy and eight oöphorectomies with two deaths.

The hysterectomy was performed in the hospital of the University on May 22d, and I was aided by Drs. E. Martin and Barber and by my son. The woman was single and forty-seven years old. She had multiple fibroid tumors of the womb, causing menorrhagia and a constant pain which crippled her. The tumors had very firm parietal, intestinal, and omental adhesions, and the incision needed for their removal was a long one. The stalk formed by the cervix uteri was about four inches in diameter. It was brought outside of the wound and secured by two long pins together with Koeberlé's wire

clamp. The whole mass, drained of its blood, weighed thirteen and a half pounds. The recovery was prompt.

The oöphorectomies were performed for the following reasons: Three for multiple fibroid tumors of the wound; two for pernicious menstruation, which crippled the patients for three out of four weeks; two for ovaralgia, and one for ovarian dysmenorrhœa and threatened insanity. The two which died were cases of multiple fibroid tumors of the womb. The ovaries were greatly lengthened out from the growth of the tumors; they had very short and broad pedicles, and were very hard to get at, owing to adhesions contracted by the uterine tumor. Case 8 presents the anomaly of the extirpation of the ovaries for ovaralgia, resulting in a recovery, but not in a cure. My explanation is this, that while I believe the pain was ovarian, it had persisted in the ovarian nerves on account of the opium habit, which the patient had not given up. The left ovary, to which the pain was referred, was prolapsed and had also undergone cystic degeneration. The right ovary seemed healthy. In all the eight cases some evidence of disease, either of the ovaries or of the tubes, was invariably found.

Besides the above, I had a fatal case of exploratory incision. The woman was a great sufferer and much reduced. The tumors proved to be malignant and were not touched. Three days afterwards she died suddenly with symptoms of embolism.

PRELIMINARY REPORTS OF THE COMMITTEE ON DISINFECTANTS OF THE AMERICAN PUBLIC HEALTH ASSOCIATION.

VI.

CARBOLIC ACID.

By CHARLES SMART, M.D.,
SURGEON U. S. A.

Carbolic acid may be said to have been recognized as an antiseptic from the time of its discovery by Runge, in 1834, in the distillate from coal-tar. This is sufficiently attested by the analogies which led to the use of the name *coal-tar creasote* and the well-known preservative action of the product from wood. In Watt's *Chemical Dictionary* we are informed concerning the properties of carbolic acid, that "fish and leeches die when immersed in the aqueous solution and their bodies subsequently dry up on exposure to the air without putrefying." The deodorant action of the acid was recognized as due not to a destruction of the offensive products of putrefaction, as in the case of some chemicals, but to an influence on the process which gave rise to them. When this process was shown to be dependent on the development, growth, and multiplication of certain bacterial forms, a destruction of their germs, or at least an interference with the conditions congenial to their growth, was of necessity assumed. On this Professor Lister, in 1867, based the use of the acid in Antiseptic Surgery. The success attending his method of treatment spread the fame of carbolic acid; and its known and well-proved antiseptic properties led to its investiture with disinfectant properties which were by no means proved. It was used largely as a disinfectant in Europe, and for several years was held in a similar high repute in this country.

The first experiments to test its value failed to distinguish between the antiseptic and disinfectant properties. As late as 1870, Crace Calvert's experiments[1] had a reference only to the delay in the exhalation of putrefactive odors from organic substances. Albumen and flour-paste, which became offensive in five and seven days respectively, when exposed to the air, were preserved for eleven and twenty-five days when mixed with five per cent. of the acid. Even the experiments of Schroeter,[2] in 1878, seem mainly directed to define an antiseptic value. A liquid characterized only as teeming with bacteria, had its contained organisms rendered motionless and precipitated by the addition of 0.05 per cent. of the acid—a dilution of 1 : 2000. Raw flesh in a dilution of 1 : 10,000=0.01 per cent., began to putrefy at the end of six days; in 1 : 2000=0.05 per cent., the liquid, notwithstanding the presence of the flesh, remained clear and without odor for four weeks; in 1 : 1000=0.1 per cent., the preservation was prolonged for from six to eight weeks, while in 1 : 500=0.2 per cent., the liquid remained clear and free from all organisms for many months. Hence he considered that a solution containing 0.1 per cent. of the acid is one in which no low organisms can exist, and that a dilution of 0.01 per cent. will retard their development for some time.

The acid was recognized as being specially destructive to the moulds, a much smaller quantity sufficing to destroy them than was requisite to insure protection from the bacteria of putrefaction. Thus, Baxter[3] quotes Manassein as authority for the statement that one-sixteenth of one per cent. deprived the spores of penicillium of their germinating power; and Schroeter found that the vapor of the acid arrested the development of penicillium and mucor and destroyed their spores. One thorough fumigation of a mould-infected chamber acted so radically that for six weeks afterward no trace of the fungi was discovered.

It became evident, however, to the experimenters having this matter in view, that the acid might interfere with the development of the bacteria of putrefaction without destroying their power of multiplication when transferred to a more congenial environment. Hence, culture experiments were instituted on the bacteria that had been subjected to the influence of the acid. Moreover, it was recognized that experiments on the bacteria of putrefaction were by no means satisfactory as arguments on the vitality of the disease germs which were concerned in the process of disinfection. Hence were instituted experiments on certain infective matters.

Braidwood and Vacher investigated the action of

the acid on vaccine lymph in 1870, and verified their results in 1876.[1] On four children vaccinated with lymph containing 2.5 per cent. of acid, six vesicles were obtained at ten points of insertion. In these instances the lymph was removed from the arm, mixed in a watch-glass with the acid and applied at once. A second group of children, five in number, were vaccinated in a similar way; but the mixtures used had been preserved in Husband's capillary tubes for seventeen days, three weeks, four weeks, and six weeks respectively. These inoculations all failed and the children afterwards underwent successful normal vaccination. Similar results were obtained by trying the carbolated lymph on a heifer.

Meanwhile, Dougall, in 1873, operated on vaccine lymph, making use of subsequent vaccination as the test of the action of the carbolic acid on the virus. He exposed the lymph in a bell jar of one cubic foot capacity for thirty-six hours, and after mixing it with glycerine and water, sealed it up in capillary tubes until used for vaccination. The lymph thus treated produced satisfactory vesicles. Led by this result, he then treated fresh vaccine with one per cent. of pure carbolic acid and found its infective property undiminished. But about the same time Hoppe Seyler[2] determined that two per cent. of the acid destroyed the activity of vaccine virus; and two years later Baxter, in his careful work for the British health authorities, was also successful in destroying the virus, as proved by subsequent inoculation with the disinfected matter. He exposed dry vaccine to carbolic acid vapor in a bottle one-third filled with the acid and found that when the period of exposure was less than thirty minutes the infection was but slightly if at all impaired. When the exposure extended to thirty minutes, disinfection was effected in one specimen, while another produced two vesicles for three insertions. In two instances in which the exposure was prolonged for sixty minutes the virus proved inefficient when subsequently used. He also found that while the presence of one per cent. of carbolic acid in liquid vaccine exerted no influence on its activity, two per cent. destroyed its infective power with certainty.

Dougall, returning to this subject in 1879,[3] concluded from some of his experiments that if the vaccine were used immediately after its exposure to the carbolic acid, or if hermetically sealed in the meantime, the virus would fail, but that if exposed to the air after being carbolized it would recover its activity. Thus sixty parts of vaccine and forty of acid, when used immediately after mixture, gave no results, but when used after a free exposure to the air during fourteen days, it was found to have recovered its active properties. He therefore concluded that the infective particles of the lymph became covered with the coagulated albumen of the vaccine liquid, and that in vaccination the free acid coagulated the contents of the dermal capillaries and rendered absorption impossible. But these experiments of Dr. Dougall did not succeed in the hands of J. W. Miller, of Dundee.[1] He prepared four specimens, each containing two parts of carbolic acid and three of vaccine. The mixtures were exposed to the air for fourteen days before use; and in each of the four experiments the lymph was barren. Two experiments were made with vaccine which had been exposed to the air for fourteen days after its admixture with five per cent of the acid; in one of these the lymph was barren, in the other an imperfect vesicle was obtained. One experiment, however, appeared to verify Dr. Dougall's results; equal parts of vaccine and glycerine of carbolic acid, after exposure to the air during fourteen days, yielded a good vesicle. But Miller was inclined to view this result with suspicion, and attributed it to pure lymph rubbed off by inadvertence from some of the other points of insertion on the child's arm.

But other liquids containing germs or infective matter were used by the investigators. Rosenbach,[2] in 1873, injected dogs and rabbits with unhealthy pus, to which five per cent. of the acid had been added, the general tenor of his results showing that disinfection had been accomplished. Baxter, two years later, experimented with the virus derived from the peritoneal cavity of guinea-pigs that had succumbed to infective peritonitis. The length of time during which the virus was exposed to the action of the acid varied from thirty minutes to three hours, thorough admixture having been effected in the meantime. In one set of experiments, two per cent. and one per cent. of the acid destroyed the infection, as the animals inoculated with the mixture did not suffer. In a second series of experiments, one per cent. was efficient for protection, but with a virus containing only 0.5 per cent., the animal died in forty hours from acute cellulitis. In a third series, one per cent. was efficient, but death occurred with 0.5 per cent. in eighteen hours. In the fourth series, one per cent. proved again protective against the infective material. Similar inoculation experiments with the virus of glanders showed that two per cent. of carbolic acid destroyed its infection, while 0.5 per cent. failed to act as a disinfectant.

By culture-experiments, Sternberg, in 1883,[3] showed that the micrococcus of pus has its vitality destroyed so that it fails to develop when introduced into a sterilized bouillon after an admixture of two hours with 0.8 per cent. of the acid, while with 0.5 per cent. its subsequent cultivation was successful; and that the micrococcus of septicæmia is destroyed by 0.5, but not by 0.25 per cent. This defines the germicide limits of the acid in respect to these organisms. On the other hand, when carbolic acid was added to the sterilized culture-liquid, a much smaller percentage than was needful for a germicidal action sufficed to prevent the development of the micrococci of pus and of septicæmia when implanted for cultivation. Thus, 0.2 per cent. prevented the development of the organisms, while 0.1 per cent. failed to protect the culture-liquid from its attack. Similar results were obtained with the micrococcus

of septicæmia. This defines the antiseptic limits of the acid in respect to these organisms.

Baxter was of opinion that the length of time during which the acid was permitted to act upon the infective material was of no importance, provided that thorough mixture was insured. This implies a belief in the instantaneous action of the acid on the active principle of the virus. Some experiments by Koch[1] in 1881, Salmon[2] in 1883, and Schell and Fischer[3] in 1884, indicate that time of exposure, as well as strength of solution, enters as an element into the question of disinfection. Thus the last-mentioned investigators, operating on fresh tubercular sputa, found that disinfection was accomplished by treatment with three, two, or even one per cent. of acid for twenty hours; but that five per cent. failed to disinfect when the period of digestion was limited to two hours. Post-mortem examinations discovered sound organs in the animals inoculated with the former mixtures, and tubercular disease in those of the specimens treated with the latter and stronger mixture. Salmon, operating on the micrococcus of fowl cholera, obtained the destruction of the virus by one per cent. of the acid, the test being inoculation. In some experiments in which the test was cultivation, one per cent. succeeded and 0.5 per cent. failed to destroy the power of germination when the digestion with the acid was continued for one and a half hours; but 0.5 per cent. was successful when the digestion was prolonged for twenty-four hours.

The bacilli and spores of anthrax have been subjected to a number of experiments, of which those of Davaine[4] are the earliest. The blood of an infected animal, diluted with one hundred parts of water, was used. This was found to be speedily fatal to guinea-pigs when injected under the skin, but its virulence was destroyed on treatment for an hour with one per cent. of carbolic acid. Koch found that the *spores* of anthrax had their vitality destroyed by immersion for twenty-four hours in a five per cent. aqueous solution of the acid. A two per cent. solution was not efficacious; but after five days' digestion in this solution the development of the spores was somewhat retarded. Further experiments showed entire failure of disinfection with a one and two per cent. solution; success after seven days with three per cent.; after three days with four per cent. and after two days with a five per cent. solution. Culture in gelatine was the test employed in these instances. On the other hand, the *bacilli* were destroyed by exposure of from two to twenty-five minutes in aqueous solutions containing from five to one per cent. of the acid, the test being culture in solidified blood-serum. The culture in gelatine of the anthrax *spores* was not prevented by their antecedent immersion for one hundred and ten days in oil containing five per cent. of the acid nor by seventy days in alcohol of the same carbolic strength. An oleaginous five per cent solution diminished the development of the *bacilli* in three or four days, and accomplished disinfection on the sixth day, as shown by the failure of subsequent efforts at cultivation. Even a one per cent. solution in oil destroyed their power of development on the sixth day, but it is to be observed that a similar result followed the use of pure olive oil. Arloing, Cornevin, and Thomas[1] found that the virulence of anthrax spores persisted after an immersion of forty-eight hours in alcohol containing two per cent. of the acid, while it was destroyed by the action of the same percentage in water. Blyth[2] also experimented with these spores. He showed the inefficiency of the carbolic acid powders—Calvert's, Jeyes's, and McDougall's. The spores invariably developed notwithstanding contact with the powder for twenty-four hours. A one per cent. carbolic solution had no effect on their development; five per cent. retarded their growth; twenty-five per cent. in alcohol rendered them incapable of germinating in broth.

While these investigators were testing the power of carbolic acid on certain disease-producing substances, many series of experiments were performed on the bacteria of putrefaction, with a view of determining the germicidal as well as the antiseptic powers of the acid on the organisms, the latter being expressed by the quantity of acid required to be added to a nutritive liquid in order to restrain their growth, and the former to prevent them from multiplying when subsequently transferred to a suitable culture-liquid.

Baxter's experiments showed that 0.5 and 0.1 per cent. were required for the germicidal action, the larger percentage being requisite when the liquid was albuminous. Hamlet[3] operating on Pasteur's liquid containing B. punctum, B. termo, and M. crepusculum, found a slight diminution in the number of moving bacteria after standing five days mixed with one per cent. of carbolic acid, while with five per cent. few of the bacteria showed signs of movement. Nevertheless, in this last experiment their vitality persisted, for when a little of the solution was transferred to a large quantity of Pasteur's liquid the whole was in two days teeming with bacteria. Notter's[4] results were to the effect that 3.3, 5, and 6 per cent. of carbolic acid did not destroy the movements of the bacteria in a putrid infusion of beef, even after the lapse of seven days. Jalan de la Croix[5] found that when two drops of a liquid teeming with bacteria are added to a sterilized meat-juice, the acid must be present in the proportion 1 : 669 to prevent development; but to produce a germicidal effect in this weak bacterial liquid, acid in the proportion 1 : 22 had to be added. The bacteria in broken-down meat infusion were killed by immersion for twenty-four hours in a solution of 1 : 22, although not in 1 : 42; but to prevent the development of germs when this liquid was introduced into a sterilized infusion it was necessary to give them a preparatory soaking for twenty-four hours in an acid of the strength 1 : 2.66, for a solution of 1 : 4 did not deprive them of their

fecundity. To prevent the decomposition of boiled meat-juice by germs falling into it from the air 1 : 402 was required; but for an unboiled infusion 1 : 502 sufficed; and to prevent the development of the germs in the former when transferred to a sterilized liquid, 1 : 22 was required, while those in the latter were not deprived of their germinating power by 1 : 10. Vallin[1] justly remarks of De la Croix's experiments, that they must be accepted with some reserve, since it is contrary to the general experience that a boiled liquid should require more of an antiseptic to preserve it than one which had not been boiled. Sternberg found that 0.2 per cent. was antiseptic in view of B. termo, but one per cent. was required for action as a germicide. He further found that the bacteria in broken-down beef-tea retained their vitality after an exposure of two hours to a four per cent. solution.

Turning from these experiments in which the carbolic acid was used in the form of liquid to those in which its vapor was employed, we find the following, in addition to those already mentioned in connection with antiseptics, the destruction of moulds, and of the vaccine efficiency.

Perrin and Marty[2] failed to prevent the decomposition of barley-water, milk, blood, urine, etc., by the atomization of a five per cent. carbolic liquid. Schotte and Gärtner[3] volatilized carbolic acid by heat in a closed chamber in which were exposed to the action of the vapor liquids containing bacteria and woollen cloths that had been dipped in these liquids, determining at the close of the exposure whether the fecundity of the bacteria had survived by transferring them to a sterilized culture liquid. For efficient disinfection rapid evolution of the carbolic vapors was required. The bacteria in the exposed liquids were destroyed by the diffusion of 7.5 grammes of carbolic acid per cubic metre, but those in the impregnated cloths required a stronger diffusion, 12.5 grammes, when the fabrics were damp, and 15 grammes when they were dry.

From a survey of these experiments on carbolic acid performed since the introduction of methods of precision in testing germicidal or disinfectant properties the value of the acid in these respects may be determined.

One per cent. in an aqueous solution has destroyed with certainty the virulence of septic and purulent matters, of the tubercle bacillus, and of the micrococci of fowl cholera; some of the organisms related to putrefaction have also been destroyed by solutions of this strength. But to produce these results in some instances the contact with the disinfectant had to be continued for many hours. Two per cent. of the acid in an aqueous solution was required to destroy the infection of vaccine and glanders; but some of the experiments on the former seem to indicate that no destruction of the virus was effected, but merely a suspension of its powers, which were recovered on the dissipation of the acid by subsequent prolonged exposure to the air. The spores of anthrax did not lose their ability to germinate unless treated with a five per cent. solution for twenty-four hours or with a weaker solution for a longer time. Lastly, as showing how little reliance can be placed on carbolic acid as a disinfectant except in special instances, as in those above mentioned, where its effects have been determined, the organisms in broken-down beef-tea were not deprived of their reproductive powers by treatment with four per cent. acid, Sternberg, nor with six per cent., Notter, nor with ten per cent., De la Croix; the last observer indeed asserts that about thirty per cent. (1 : 2.66) was needful to effect this object.

The large percentage of the acid required for disinfectant or germicidal action when applied directly in the liquid form, prepares us for its failure when used in the form of vapor. Douglas and Baxter, from the results of their experiments on vaccine, concluded that aërial disinfection by carbolic acid vapor was practically impossible. The atomizer, however, offered better facilities for the diffusion of the vapor, and Strott[1] in 1876, and Wernich[2] in 1883, recommended the use of the spray as protective against albuminoid contagious principles. But the experiments of Perrin and Marty and of Schotte and Gärtner demonstrated its inutility as against bacterial life.

The valuable antiseptic properties of the acid do not come within the scope of this article, although they have been in a measure indicated incidentally.

NOTE ON THE TREATMENT OF ONYCHIA.

BY CHARLES W. DULLES, M.D.,

SURGEON TO THE OUT-PATIENT DEPARTMENTS OF THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA, AND OF THE PRESBYTERIAN HOSPITAL

PRACTICE in the out-patient departments of two hospitals has brought to my notice a number of cases of this stubborn disorder, and has led to my adopting a method of treatment which is so satisfactory that I think it worth while to call attention to it. It is not new in principle, but I think the details of it are not to be certainly gathered from the suggestions which are to be found in some of the works on surgery.

The plan I refer to consists in washing the usually stinking finger or toe-end with a weak solution of permanganate of potassium, trimming the nail back to where it is attached to the matrix, dusting on a *fine powder* of iodoform, and covering the whole in with turns of a narrow strip (not more than quarter of an inch wide) of adhesive plaster. The plaster I prefer is the rubber adhesive plaster, which fits better, because it is softer than ordinary adhesive plaster, and is much easier to apply, because it requires neither heat nor moisture to fix it.

By this means, I have succeeded, so far in every instance, in getting rid of the pain, which is often excruciating; of the odor, which is almost intolerable; of the evidences of high inflammation, which are always present; and in securing a speedy re-

[1] Ventilation und Disinfection der Wohnsäume, Holtzminder, 1876, p. 19.

[2] Real-Encyclopädie der Gesammte, Heilkunde, 1883, B. 15, S. 170 et seq.

covery of what by other methods has proved an exceedingly intractable disorder.

The secret of success, I believe, lies in attention to the details of this method. The finger or toe-end must be thoroughly cleansed with the permanganate solution; the nail must be gently, but thoroughly, trimmed back till all of it that is dead is removed; the iodoform must be *finely powdered*; the adhesive strip must be smoothly applied, and in such a way as to cover the whole of the end of the finger or toe.

This latter step is accomplished by taking the thin strip of plaster, and applying it first on the proximal side of the nearest interphalangeal joint, *obliquely to the long axis of the finger or toe*, and carrying it up toward the end and round until it begins to return; by continuing these turns, the strip, with a little guidance, will gradually make first a latticed covering, and then cover up the interstices of this lattice, so as to make a complete cap. If necessary, a few strips may be applied directly over the end of the finger or toe, so as to fill up any gaps which would require too much plaster to be covered-in in the, so to speak, natural way.

Such a dressing should be removed as soon as the pain or the stinking is renewed. But usually it will give immediate and entire relief from both; in which case, I think, it is advisable to remove it at any rate in two or three days to see how the part is getting along. The second dressing, of the same kind, will often be applied to a healthy granulating surface, and form a dry, clean scab, under which the member will heal up perfectly.

I have experimented in cases which were doing well under this treatment, and have found that the adhesive plaster part of it is indispensable. As soon as it was left off the cases did badly.

Toes, I have found, are harder to cure than fingers, for obvious reasons. But in the case of both fingers and toes, I have seen children cease their complaints, resume their plays, begin to get good sleep at night, and recover the appearances of health which pain had robbed them of.

Finally, I would say that I think it important in these cases to see that the patient's bowels are once well cleared out, and then kept in good order, and to give a ferruginous tonic.

This may seem an insignificant kind of surgery, but it is not insignificant to the little sufferers, nor to their parents, nor, my observation would lead me to believe, to the medical men under whose care the patients come.

A CASE OF DOUBLE NARCOTIC ADDICTION—OPIUM AND ALCOHOL. IMBECILITY. RECOVERY.

By J. B. MATTISON, M.D.,
of Brooklyn, N. Y.

Through the courtesy of Drs. T. Gaillard Thomas, of New York, and Wm. Bayard, of St. John, N. B., there came under the writer's care, last year, a case of combined opium and alcohol taking, presenting a history and result of such importance as to render its recital probably one of interest.

Mrs ——, of Canada, æt. 34, in the summer of 1881 passed through her second accouchement during the eighth month of gestation. Her recovery was tedious, involving four or five months, during which she had much discomfort from alvine torpor, and also underwent an operation for the relief of fistula in ano. The latter was attended by severe pain, to relieve which her medical advisers gave morphia, hypodermically, and supplying her with a syringe, instructed her and the attendant in its use. This was in July, and the initial dose of the morphia was an eighth of a grain, repeated three or more times daily when the pain was severe.

She made a fair recovery from this illness, except that the power of the lower limbs was largely lost, due, it was thought, to the morphia—which she had steadily taken—and a lack of active exercise.

She had now become a confirmed habitué, and during the next two years used her opiate in increasing quantity and frequency, often repeating it every three or four hours.

During the autumn of 1883 she came under the care of a medical gentleman who was called to relieve her of severe abdominal pain and nervous derangement. Prior to this time no attempt had been made to abandon the morphia. Her new professional adviser, appreciating her situation, strongly urged an effort in that direction, but without success. Her condition had steadily grown worse, aggravated as it was by an immoderate use of brandy, of which she took at times from twelve to sixteen ounces daily.

From October, 1883, her mental and physical decline was marked, the most prominent symptoms being anorexia, insomnia, nausea, incessant thirst, subsultus, loss of memory, delirium, hallucinations, and partial imbecility. Her physician now insisted on stopping her stimulants, and succeeded with the brandy, while the morphia, which had been increased to several grains—three to five per diem—was reduced to one or two injections daily.

Despite this treatment her mental and physical status steadily deteriorated until she became completely imbecilic, and in this condition, on December 21, 1883, she came under the writer's care. So weak was she prior to leaving home, that some of her friends deemed it hazardous to make the effort—fearing she would not survive the journey—but, under the watchful care of Dr. Bayard, it was safely effected. Her physical debility on arriving was so great that she was carried from her carriage. Mentally she was a wreck. Delusions were prominent and hallucinations of sight, sound, and touch almost constant, that of touch being especially marked; patient fancying bugs and reptiles crawling over her. Her expression was idiotic; she was utterly unable to converse intelligibly, and her voice in speaking speedily sank to a whisper and was lost. In fact, such mental ravages from opium we never met.

Physically she was partially prostrated, pulse frequent and feeble, marked anorexia, furred tongue and alvine torpor: in fine, all the symptoms before noted, except delirium and subsultus. During her coming, in order to maintain strength, she had taken milk-punch freely, and was given one or two half

grain injections of morphia daily. Such was her status on arrival.

There was no history of hereditary insanity. The case seemed clearly one of profoundly, pernicious results from her double addiction, aggravated by a laudable effort to remove the cause. This being our belief, the prognosis was favorable, an opinion endorsed by Dr. John C. Shaw, Superintendent of the Kings County Insane Asylum, who was called in consultation, and verified by the result, as the further record of the case will show.

As a prelude to active treatment, the patient was given a mild mercurial, which acted well. No alcohol was allowed from the outset, and at the end of a week the morphia, which previously had been given in small doses by mouth at bed-time, was quite abandoned, and reliance placed on large doses of Indian hemp to secure sleep. As tonics, she was given daily seances of electricity, with syr. hypophos. iron, strychnine, and quinine, in two drachm doses, ter die, and full feeding.

The good effect of this regime soon declared itself, for in less than a fortnight signs of improvement presented. The earliest of these were mental. The delusions lessened and hallucinations departed, the last to leave being those of touch, which persisted for some time after the patient was able to realize that they were only the vagaries of her disordered brain. With this amendment came a better brain status in other ways. The imbecile look gave place to one of increasing intelligence, the power to converse rapidly returned, and within six weeks all traces of mental aberration had vanished. Meantime her physical condition gradually improved, though not so speedily as the mental. The appetite was slow in returning, but her muscular strength, especially in the lower limbs, the loss of which for two and a half years had prevented exercise, increased steadily, so that at the end of eight weeks she was able to take walks, drives, go shopping, attend church, etc., in fact, more out-of-door exercise than she had enjoyed for years. Her improvement in every way was notable, and persisted with little interruption until March 4, nearly eleven weeks from the date of her coming, when she left our care. Tidings, direct and indirect, received of late report her doing well.

This case presents several points worthy of detail. In our judgment, the course of the medical gentleman in supplying this patient with a hypodermic syringe and solution of morphia, with instructions for self-taking, unless absolutely unavoidable, was—to put it mildly—exceedingly indiscreet. Such action and advice are almost *certain* to end in addiction. The effect, even under professional attention, is too often disastrous, and the chance of escaping when left to caprice of the patient is small indeed. We believe that patients should *never* be allowed to give themselves injections, if at all possible to avoid.

When her initial illness ended, this patient was an opium habitué. A much more limited time than that will often suffice. We have repeatedly known as many weeks to beget addiction.

This case adds another to the instances in which addiction to one narcotic tends to excess in another. While these are infrequent as compared with those in which one is used, they are sometimes quite notable. We recall that of a Canadian gentleman who some time ago consulted us, who had taken for several years 10 to 20 grs. of morphia, subcutaneously 60 to 90 grs. of chloral, and 1 to 2 pints of whiskey daily. Physical examination disclosed organic heart lesion, and care of this case was declined. As a rule, the ruinous results exceed those of a single addiction, while the prospect of permanent cure is always less hopeful. In our patient the pernicious effect on the brain was notable, more so than we have ever observed. While deviations from normal cerebral action are sometimes observed in cases of confirmed opium-taking, it is rare that they are so pronounced as in this instance. Doubtless they were aggravated by the alcohol, yet morphia was the main factor. And it is of interest to note that the attempt at renouncing the narcotics intensified the mental disorder. Obersteiner (*Brain*, Oct. 1882), demurring to Levinstein's statement that the psychical disturbances caused by morphia cease within a few hours, affirms that "mental diseases arising in the course of morphinism are of the most intractable kind when once fully developed. Not only do they not disappear on depriving the patient of morphia, but they then usually get worse." This case tends to prove the latter part of his statement. As one medical gentleman informed us, "the condition in which you saw her was the result of the addictions aggravated by the attempt to quit them." But the mental disorder was not of the "most intractable kind," for improvement was prompt and progressive, much more so than anticipated, as it was thought several months rather than weeks would be needed to repair the damaged brain.

Regarding alienation caused by opium, Obersteiner thinks it frequent, asserting that "a man who consumes large quantities of morphia during a number of years will display many nervous symptoms, and that the continued intoxication attacks the psychical much more constantly than the somatic life." He further states: "The degree of mental aberration arising from protracted use of the drug is very variable. There may indeed be individuals who retain their power of mind in spite of it, but the number is much greater of those who betray a marked alteration of their intellectual and moral life, and in not a few cases finally the point of distinct aberrations is reached. This usually consists of a depressed state with suicidal tendencies, occasionally with violent excitement and hallucinations;" and he sums up his views with the statement that "in most cases the protracted use of morphia in large doses is followed by psychical alterations of a lasting nature which may amount to decided insanity."

With these opinions we are not in full accord. Our experience has been much more favorable. We have observed many cases of opium addiction, among those who had taken morphia in large amount for several years, yet the number with marked mental derangement has been small. Depression has been common, so, too, irritability of temper, but we recall only one instance in which suicidal or homicidal tendency existed, and but a single case that we deemed "decided insanity." Far oftener,

physical symptoms presented. In some form these have been almost constant, so that on this score also, our observation has been at variance with Obersteiner.

Regarding treatment, one point deserves special mention—that is, the effect of Indian hemp in large doses. In this instance it quite maintained the power ascribed to it by Moreau of removing hallucinations. Again and again—often by the patient—was this noted. Its hypnotic action also was very satisfactory. As a soporific in ex-opium habitués, Cannabis Indica is of great value. They may be peculiarly susceptible to its good effect, but certain it is we know of nothing equalling it, and employ it almost exclusively. For details regarding its use, vide *Canada Medical Record*, Jan. 1885.

Finally, the history of this case is of value as warranting hope of entire recovery under conditions that seemingly offer little promise of success.

HOSPITAL NOTES.

MEMORIAL HOSPITAL, ORANGE, N. J.

Service of Dr. William Pierson.

HERNIOTOMY PERFORMED UPON A PATIENT HAVING FACIAL ERYSIPELAS; RECOVERY.

(Reported by James Y. Simpson, M.D., House Surgeon.)

Mary C., æt. 28, servant. The day before her admission, which was the 12th of December, the patient noticed a tumor in her right groin, which gave her much pain. The pain continued during the night, and was accompanied by vomiting. It was impossible to ascertain whether the vomiting was stercoraceous or not. No intestinal evacuation occurred after the appearance of the tumor, and a large enema failed to produce one. On admission, the patient was found to have a tumor in the right groin, which was dull, elastic, painful, and as large as an egg. On the face was a well-marked erysipelatous inflammation, confined chiefly to the left side and sufficiently intense almost to close the eyes; this, the woman said, had appeared three days previously. The patient was placed upon the table, and reduction of the hernia attempted under an anæsthetic. This, however, proved unsuccessful, and, after due consultation of the surgeons, it was decided that, in view of the pain and vomiting, the intestine was strangulated, and inasmuch as taxis had failed, the only resort was herniotomy—this operation offering a much better chance than delay, in spite of the facial erysipelas. After shaving the part and washing it with a solution of mercuric chloride, the usual incision was made, and the tissues divided upon a director until the sac was reached.

Digital exploration then showed that the hernia was femoral, the band of constriction being internal and anterior to this ring. The constricting band was easily divided and the intestine returned without opening the sac. The edges of the wound were brought together with a continuous catgut suture, and the wound dressed with carbolized gauze, absorbent cotton, oakum, and a spica bandage. The operation was performed by Dr. William Pierson, assisted by the surgical staff. A solution of bisulphite of soda was applied to the erysipelas. During the night the patient vomited a few times, and had a temperature of 103½° the next morning. Her pain was slight and easily controlled by sulphate of morphia administered hypodermatically.

The following day her temperature was 102¾°, and she complained of "uneasiness" across the abdomen. The erysipelatous condition of the face was more marked, one or two blebs appearing on the ear. On the next morning, her temperature was 100°, and the "uneasiness" of the bowels continuing, an enema was given and followed by relief.

From this time on her temperature remained normal, and the erysipelas was so near well on the seventh day after her admission that no further treatment was necessary. On the tenth day after the operation, the original dressing was removed from the wound and union found to be complete, with the exception of its lower extremity, which was discharging a small amount of pus. After a few days, the patient was able to return home, having entirely recovered from the operation and the erysipelas. This result is noticeable, as antiseptic precautions alone were employed to obtain it.

MEDICAL PROGRESS.

Impacted Caseous Glands in the Trachea causing Sudden Death.—At a recent meeting of the London Pathological Society, Dr. Percy Kidd showed this specimen, taken from the body of a boy aged 7. He was noticed to have a croupy cough, and somewhat stridulous breathing during life. No physical examination had been made. One night, after running about in the daytime, and having complained of no urgent symptom, he suddenly awoke, screaming, coughing, and struggling for breath. He died in about ten minutes. At the autopsy the mediastinal glands were all enlarged and caseous; the enlargement was most marked on those glands lying in front of the trachea; the lower end of the trachea was blocked up by an oval, partially softened caseous gland, which had been extruded through an ulcerated opening in the anterior wall of the trachea, just above the orifice of the left bronchus. The perforation led into an encapsulated space in front of the trachea, which contained caseous débris and traces of gland tissue. The heap contained a few miliary tubercles in their upper lobes, but were otherwise healthy. The heart was firmly contracted and practically empty, and was quite healthy. All the other viscera were healthy. It was remarkable that although the child evidently died of asphyxia there was no distention of the right side of the heart found after death.

Dr. Goodhart had seen a very similar case; an ulcer had formed in the left bronchus through which some softening caseous gland had been squeezed, and plugging the bronchus had caused sudden death. In another case he had reason to suspect this condition, but there was no *post-mortem* examination.—*Med. Times*, Feb. 21, 1885.

Pulsatile Angioma.—M. Laedrich, in the *Archives de Med. et Pharm. Militaires*, summarizes the treatment of pulsatile angioma by electricity as follows:

1. It must be certain that the point of the needle is in direct contact with the blood to be coagulated. A Pravaz needle is useful for this purpose.

2. The positive pole must be in relation with the tumor.

3. The negative pole is advantageously placed at a distance from the tumor—*e. g.*, in the palm of the hand.
